BURNING GLASSES,

OR

BURNING MIRRORS.

Burning Glasses.

THE name of certain glasses or mirrors which have the property of inflaming combustible substances by the action of the sun's rays, being so formed as to collect all the rays which fall over their whole surface into a single point or spot, more or less distant, according to the form of the glass. In this point the natural heat of the sun is found to be so augmented, owing to such a multitude of rays being all concentrated in so narrow a space, that it produces an intense temperature, and such as is quite sufficient, even with very ordinary glasses, to inflame wood or other combustible substances. There is always one particular point at a certain distance from the glass where the heat is the greatest. If we place the burning body nearer the glass the heat diminishes, till it will no longer take fire; and if we place it farther from it, the same effect takes place. Hence this point, where the heat is the most intense, has received the name of the *focus* of the glass.

Focus.

Refracting and reflecting glasses.

This property of burning glasses, however familiar it may now appear, is certainly very remarkable, and must, at the time of its invention, have excited no small degree of astonishment and of interest, from the striking nature of the effect, and from the uses to which it might be applied. The operation is now perfectly understood from the principles of optics, and is indeed extremely simple. See OPTICS. The rays of light are collected either by refraction in passing through a transparent glass, or by reflection from the polished surface of a mirror. Burning glasses are hence divided into two kinds,—refracting glasses, which can only be made of glass or other transparent substance; and reflecting glasses, which are either made of glass silvered behind, or of polished metal, or any other reflecting substance. Reflectors of polished metal are generally termed *specula*. In the former kind the glasses are of a convex form, and collect the rays of the sun into a focus behind the glass, as at fig. 1, Plate CLII.; each ray, as it strikes more or less obliquely on the surface of the glass, being more or less bent out of its natural course by the refractive medium, so that they are all made to converge to one point or focus of refraction. Reflecting glasses, again, are all concave, and the rays of the sun are collected into a focus in front of the mirror by reflection; each ray, as it strikes more or less obliquely on the surface of the mirror, being reflected back, but at the same time inclined to the centre so that they are all made to converge to a point or focus of reflection in a similar manner, as at fig. 2.

In both these cases it is by the peculiar shape or figure of the glass or mirror that the convergence of all rays to one point is produced; and to ascertain therefore the figure which would do this most perfectly becomes an important object in the construction of glasses, and is, besides, a curious mathematical problem. In the case of refracting glasses, where we have a double surface, one on each side of the glass, it was first shown by the celebrated Descartes, that a glass having its exterior surface convex, and a portion of an elliptic curve, while its interior surface was concave, and formed a portion of a circle, would cause parallel rays, or those of the sun, to converge to a perfect focus, as at fig. 3, where the exterior surface of the lens BAC forms a portion of an ellipse, whose

greater axis AX is to the distance between the foci Ff, as the index of refraction is to unity, and a circle whose centre is at F. Various other forms have been proposed, but, owing to the great difficulty of forming glasses of these compound curves, it was found more convenient in practice to rest content with the exterior surface BAC, a portion of the simple curve of the circle or sphere, particularly as in large glasses, or those of slight convexity, the sphere approaches very nearly to that of the ellipse. Each side of the glass, therefore, is carefully turned and ground into the portion of a sphere, forming together what is termed a *lens;* and the greater the radius of convexity is, the greater is the distance of the focus from the glass. It happens by a curious coincidence, that in glass the focal distance of parallel rays, usually termed the *principal* focus of the lens, in a double convex lens, is just equal to the radius of convexity. In every burning glass, therefore, of this description, it is easy to find the focus by measuring from the centre of the lens a distance equal to the radius of curvature. In the case of burning mirrors, the true figure for converging the rays to a perfect focus is that of the parabola; a form which is frequently constructed, the mirrors being either turned or hammered out of metal, and the figure therefore more readily attained than in glass. The focal distance is always equal to the radius of the concavity at the centre of the mirror. Hence in large mirrors of a shallow concavity, or with a large radius, the spherical form will approach very nearly to that of the parabola, and will therefore produce very nearly the full effect of it.

Focal Image.

The focus may also be found practically by holding the glass up to the sun, and observing where the concentration of the light is the greatest. In doing this a remarkable circumstance is observed. However perfect the figure of the glass, the rays in the focus are never converged to a mathematical point; they are always diffused over a certain space, forming a spot of determinate magnitude. The reason of this will appear very obvious, when we consider that the sun presents a very sensible magnitude, even at the enormous distance at which he is viewed. The rays from different parts of the body, from the opposite limbs, for instance, instead of being parallel, subtend sensible angles. Though all the rays therefore from any one point in the sun are sensibly parallel to each other, and those which fall on different parts of the glass from this single point are all converged to a mathematical point in the focus, this is not the case with rays coming from different points of the sun. These not being parallel, cannot by any means be thrown together in the focus, but each to a distinct point corresponding to that from which it issues in the sun, whether by refraction or reflection, so as to form on the whole an image or figure of the sun, subtending the same angle at the glass as the sun does. This is evident from an inspection of figures 4 and 5, where the rays from each limb by refraction cross one another in the centre of the glass, and again diverge, forming the boundary of the focal image at the same angle as the image itself, or by reflection meet and diverge in returning at the same angle. Hence it follows that the magnitude of the focal image will depend entirely on the focal distance, and in no respect on the magnitude of the glass or mirror. The greater the focal distance the larger will the image be. In every case it will be proportional to the sine of 32′, the angle at which the sun subtends at the glass; and hence the focal diameter will be very nearly $\frac{1}{100}$th part of the focal distance. Hence the reason of a very curious fact, that in any large glass or mirror, though we were to cut off a zone from the exterior circumference, it would not alter in the least the magnitude of the focal image; it would only diminish the intensity of the light. Whether the figure of the glass also be square, or circular, or elliptical, or any other shape, the figure of the image will be invariably a circle.

Limit of concentration.

Such then is the limit of concentration even for the most perfect glasses; and hence we see that it is not absolutely necessary to have the glasses of the perfect figure required by theory, at least it is not of such essential consequence as in the case of telescopes or microscopes, where the distinctness of the image is of as much consequence as the concentration of rays. Here, though the image be ever so confused, seeing it is heat only which we want, it is of no consequence, so that they fall within the limits of the focus. If the spherical figure, then, has been adapted with success to the nice purposes of vision, by using spherical lenses and reflectors of gentle curvature, much more may it suffice for burning glasses, where any imperfections of this kind are of less importance; the only effect of these being to produce in the focus a somewhat less powerful concentration of the rays. In practice, however, the difference with small glasses, such as four, five, or six inches diameter, and focal distances of two or three feet, is really hardly measurable. Even with very large glasses it is far from being considerable. In the great burning glasses of Tschirnhausen, for example, three or four feet in diameter, the focal distance was twelve feet; and hence a perfect image of the sun should have been $\frac{144}{100}$ inches $= 1{\cdot}44$ inches; and it was actually about an inch and a half. The famous lens of Parker had a focal distance of six feet eight inches; and hence the perfect image should have been 0·8 inches, and the actual burning focus was one inch diameter. In reflection, again, the mirror of Vilette had a focal length of about thirty-eight inches, and therefore an image by calculation of 0·38 inches; it was actually about the size of half a louis d'or.

Heating power.

In regard to the actual heating power of burning glasses, if this depended only on the concentration of the rays it would be easily calculated. The degree of concentration is in every case proportional as the square of the diameter of the glass to the square of the diameter of the focal image. In an ordinary reading glass, therefore, say of two inches diameter and six inches focal distance, the focal diameter being thus 0·06, the concentration would be as four to ·0036, or as one to 0·0009, or nearly 1000 times. No wonder, then, that such a glass should so readily produce inflammation. Even in some of the large burning glasses the actual concentration did not so much exceed this as might be imagined. In the compound burning glasses of Tschirnhausen the diameter of the first glass being three and four feet, and the focal diameter of the second glass only eight lines or two thirds of an inch, the concentration would be as 2304 and 1296 to 0·44, or 5184 times in the one case, and 2916 in the other. In Vilette's burning mirror the diameter was thirty inches, and the focal diameter about half an inch. The concentration would thus be 3600 times. But the most powerful of all these glasses is the compound one of Parker. In this the diameter of the first glass was thirty-two and a half inches, and the focal diameter of the second three eighths of an inch; hence the concentration was equal to 7168 times.

Effect of the natural heat of the sun.

In order, however, to calculate the actual increase of temperature, we must first know the effect of the sun's natural heat. The most accurate experiments on this subject are those made by Professor Leslie with his photometer, an instrument of great delicacy, peculiarly adapted for measuring the heat of the sun, as it is entirely free of any extraneous impression from the surrounding atmosphere. "In the latitude of Edinburgh," he says, "the direct impression of the sun at noon, during the summer solstice, amounts to 90° (= 16·2 Fahrenheit); but it regularly declines as his rays become more oblique. At the

Burning Glasses.

altitude of 17° it is already reduced to one half; and at 3° above the horizon the whole effect exceeds not 1°. In the same parallel of latitude, the greatest force of the solar beams in the depth of winter measures only 25°"[1] (= $4\frac{1}{2}$ Fahrenheit). Taking the average effect, then, at 10°, it would appear that the above reading glass would be capable of producing a heat of 10,000°, which is far above the melting point of brass, copper, silver, and lead. The glasses of Tschirnhausen would produce a heat of 29,160° and 51,840°, the mirror of Vilette 36,000°, and Parker's glass the enormous heat of 71,680°, which is nearly double the highest heat measurable by Wedgewood's pyrometer.

Effect of concentration modified.

But the temperature due to the mere concentration of the rays will evidently be considerably modified, according as the accumulating heat is more or less rapidly dissipated from the focal point into the surrounding medium; and this will depend chiefly on the conducting power of the substance receiving heat, and of those with which it is in contact. This effect is observed, indeed, in the case of a body exposed to the natural heat of the sun. As the accumulating heat raises the temperature of the body, this causes a dispersion both by radiation and contact into the surrounding atmosphere, so that there will be a stream of heat continually escaping from the body, as well as one running in; and when the final temperature is attained, these two effects will exactly balance each other, the quantity dispersed being exactly equal to that which is received during the same time. Now, the quantity dispersed must evidently be proportional to the excess of temperature of the body above the surrounding atmosphere, and also to the surface exposed. Hence a slow conducting body exposed to the sun,—a ball of wood, for instance,—will acquire a higher temperature than a similar ball of copper. In the latter the heat will be quickly diffused over the whole mass, and dispersed into the atmosphere from every part of its surface: in the former it will pass very slowly through the mass, and accumulating more at one side, and having a smaller surface to disperse itself by, will produce there a greater elevation of temperature; or if the copper be surrounded by any slow conducting substance,—if it be bedded in a mass of charcoal or brick, the temperature acquired will be greater, as in the case of fruit-trees on a wall, the brick confining the heat, and causing a greater accumulation and a higher temperature, just as the damming up of any stream of water raises the level of the fluid. The same thing must take place with the rays of light concentrated by the burning glass. The temperature in the focus must continue rising until the dispersion of the heat from the focal point equals what is constantly received; and the more, therefore, this dispersion can be retarded by the interposition of slow conducting substances, the higher will the temperature rise. It has always been found, accordingly, that refractory metals, or stones, melt much more readily when laid in a mass of charcoal. This circumstance explains a fact first proved by Buffon, and invariably experienced in burning glasses, that, even with the same degree of concentration of rays, the effect will be much greater with a large focus than with a small one. The latter operating in a very narrow space, and dispersing the heat rapidly into the surrounding mass, there is little left for accumulation. In the former, the heat increasing as the square of the diameter, while the dispersion into the surrounding substance only increases merely as the diameter, much more remains to accumulate in the centre; and the central portion of the focus, indeed, being surrounded by a zone almost as hot as itself, much less dispersion can take place, and the temperature, therefore, will rise much higher. If we take, for example, a glass two inches diameter, with a concentrating power of 300, and another six inches diameter of the same power, the one will inflame paper in two or three seconds, while the other will hardly accomplish it at all. These circumstances, therefore, greatly modify the effects of concentration, and serve to account for the very feeble powers of small glasses, and the intense heat of larger ones not greatly differing in concentrative action. The most powerful glass, for instance, ever constructed, was that of Parker, and yet its concentrative power was only seven times greater than that of an ordinary reading glass; and this is the reason also, as we shall see, that the reflecting mirrors of Buffon for burning at a distance produced such powerful effects, the concentration being small compared with that of single glasses, but the focal image much larger.

History and description of burning glasses.

Such being the general principles of burning glasses and mirrors, we shall now describe some of the principal instruments of this kind which have been constructed, and their effects. The invention of mirrors or looking-glasses, constructed probably of polished brass, remounts to a very remote antiquity, as they are mentioned by Moses in the sacred writings. At what period they were employed in a concave form to concentrate the solar rays by reflection is not known, but it is very probable that mirrors of this kind were used to rekindle the vestal fires. Plutarch, in his life of Numa, 700 years before Christ, describes the σκαφεῖα, or dishes which were employed for this purpose, and which appear to have been concave segments of a sphere; and he states that the combustible matter was placed in the centre, meaning, no doubt, the focus or centre of concentrated rays. In the time of Socrates, 430 years before Christ, the manufacture of glass had made considerable progress; and it appears from a passage in one of the plays of Aristophanes, that the use of burning glasses was common. The author introduces Socrates as giving lessons in philosophy to Strepsiades, a citizen of Athens, and a man of low cunning. The subjects of these lessons are silly trifles, intended to make Socrates appear ridiculous. Strepsiades, after having asked him how he should avoid paying his debts, proposes the following expedient himself:—"*Strepsiades*, You have seen at the druggists that fine transparent stone with which they kindle fires? *Socrates*, You mean glass, do not you? *Strepsiades*, The very thing. *Socrates*, Well, what will you do with that? *Strepsiades*, When a summons is sent to me, I will take this stone, and, placing myself in the sun, I will melt all the writing of the summons at a distance." The writing, as we know, was traced on wax spread upon a more solid substance.

This description must refer to a burning glass by refraction. Several other ancient observations on the same phenomenon exist. Pliny mentions globes of glass or of crystal, which, being exposed to the sun, would burn clothes, or the flesh of a patient when cauterization was requisite. *Hist. Nat.* lib. xxxvi. and xxxvii. Lactantius, who lived about the year 303, says, "a globe of glass filled with water, and exposed to the sun, will kindle a fire even in the coldest weather." (*De Ira Dei.*)

Burning glasses of Archimedes.

But the most memorable account of burning glasses, and of their effects in all antiquity, and what has excited no small degree of speculation in succeeding times, is the extraordinary achievement ascribed to Archimedes, of setting fire to the Roman fleet engaged in the siege of

[1] *Experimental Enquiry into the Nature and Propagation of Heat*, p. 440. Also, by the same author, *An Account of Experiments and Instruments depending on the relations of Air to Heat and Moisture.*

Syracuse, "launching against it," as Buffon says, "the fire of the solar beams." This, if it can be proved, must, without doubt, be viewed as the most surprising effort of genius and practical skill which the history of human invention presents. By modern opticians, at the head of whom stood Descartes, the fact was long treated as fabulous, chiefly on account of its supposed impracticability; and no doubt this would be the case with single concave mirrors or reflectors, as they imagined Archimedes to have used, and which could not obviously be constructed of sufficient magnitude and focal distance to have any sensible effect. But if we suppose, as is far more probable, and as it is actually described by some authors, that the effect was produced by a number of plane mirrors arranged in a curve, and all uniting their rays in a focus, the impossibility of such a combination is by no means clear; and in fact its perfect practicability, first suggested by Anthemius, and rendered extremely probable by Kircher, was demonstrated by Buffon, and the apparatus actually constructed by him, so as to kindle wood and other inflammable substances at the distance of 200 yards. No doubt, therefore, can remain as to the possibility of producing the effects described. The only question now is in regard to the probability of the fact itself, and the evidence advanced for its support. In the first place, there is nothing improbable in the situation of the place; for Kircher, in his great zeal to throw light on this curious subject, actually made a voyage to Syracuse, in order to examine the situation of the hostile fleet, accompanied by his pupil Scholtus, and they were both satisfied that the ships of Marcellus could not have been more than thirty paces distant from the place where Archimedes might have stood; and in regard to an objection which has been stated, that the vessels might have moved out of the way of the glasses, this does not seem to have much weight, as a moment might have been chosen when they were off their guard, and the glass could have been turned so as to follow them to a certain extent; besides that, the vessels might have been at anchor, or even aground at the time, and not capable of moving away with sufficient expedition. Let us just consider, therefore, the evidence for the fact itself. On the one hand, we have Polybius, Livy, and Plutarch, all silent on the subject, affording certainly a strong proof against the fact, when we consider also that the two former describe so particularly the mechanical contrivances of Archimedes; on the other hand, it has been positively affirmed by Vero, Diodorus Siculus, and Pappus; and though the works of the latter, which speak of the siege of Syracuse, are now lost, they existed in the twelfth century, and the passages which speak particularly of the burning glass of Archimedes are quoted by Zonaras and Tzetzes, writers of that period, and who appear incapable of inventing such a story of themselves. Zonaras states that "Archimedes burnt the fleet of the Romans in an admirable manner, for he turned a certain mirror towards the sun, which received its rays. The air having been heated on account of the density and smoothness of the mirror, he kindled an immense flame, which he precipitated on the vessels which were in the harbour, and reduced them to ashes." He then adds that Proclus, taught by this example, burnt with mirrors of brass the fleet of Vitellius, who besieged Constantinople under the emperor Anastasius in the year 514. Tzetzes, referring to the same authorities, states, that "when the fleet of Marcellus was within bow shot, the old man (Archimedes) brought out a hexagonal mirror which he had made. He placed at proper distances from the mirror other smaller mirrors, which were of the same kind, and which were moved by means of their hinges and certain square plates of metal. He afterwards placed his mirrors in the midst of the solar rays precisely at noon-day. The rays of the sun being reflected by this mirror, he kindled a dreadful fire on the ships, which were reduced to ashes at a distance equal to that of a bow-shot. Dion and Diodorus, who wrote the life of Archimedes, and several other authors, speak of this fact, but chiefly Anthemius, who wrote on the prodigies of mechanics. It is in these works that we read the history of the conflagration occasioned by the mirror of Archimedes."

Testimony of Anthemius.

This passage contains evidently a description of a combination of plane mirrors, so adapted and set to the position of the sun as to unite all the rays reflected from them into one focus. Besides these, we have the direct testimony, as above noticed, of Anthemius of Tralles, an eminent architect, and one besides deeply learned in the mathematical sciences, particularly mechanics. He flourished about the end of the fifth century, in the time of Justinian, with whom he was a favourite, and who employed him in the erection of various edifices, particularly the church of St Sophia at Constantinople, which he carried on for some time in conjunction with Isidore, and, after his death, finished himself. He was also a disciple of Proclus, from whom he may have received information regarding burning mirrors. In a fragment entitled περι παραδοξων μηχανηματων, *Of Wonderful Machines*, and translated and illustrated by Dupuy, a member of the Academy of Belles Lettres in 1777, Anthemius treats particularly of the burning mirrors of Archimedes, on the effects of which he never seems to entertain any doubt. After acknowledging that it was universally admitted in his time that Archimedes had destroyed the Roman fleet by means of burning mirrors, Anthemius observes, "Let us, therefore, bring and collect at one point other different rays, by means of plain and similar mirrors, in such a manner that all these rays, united after reflection, may produce inflammation. This may be effected by means of several persons holding mirrors, which, according to the positions indicated, send the rays to one point.

"But, in order to avoid the embarrassment resulting from intrusting this operation to several persons (for we shall find that the matter intended to be burnt does not require less than twenty-four reflectors), the following construction may be followed: Let there be a hexagonal plain mirror, and other adjoining similar mirrors, attached to the sides of the hexagonal mirror by the smallest diameter, so that they may be moved on these lines by means of plates or bands applied, which unite them to each other, or by means of what are called hinges. If, therefore, we bring the surrounding mirrors into the same plane with the mirror in the centre, it is clear that all the rays will undergo a reflection similar and conformable to the common position of all the parts of the instrument. But if, the centre mirror remaining as it were immovable, we dexterously incline upon it all the other mirrors which surround, it is evident that the rays reflected by them will tend towards the middle of the place where the first mirror is directed. Repeat the same operation, and around the mirrors already described placing other similar mirrors, all of which may be inclined towards the central mirror, collect towards the same point the rays which they send, so that all these united rays may excite inflammation in the given spot.

"But this inflammation will take place better if you can employ for this purpose four or five of these burning mirrors, and even seven, and if they are all at the same distance from the substance to be burnt, so as that the rays which issue from them, mutually intersecting, may render the inflammation more considerable. For, if the mirrors are all in one place, the rays reflected will intersect at very acute angles, so that all the place around the axis

Burning Glasses.

being heated, the inflammation will not take place at the single point given.

"It is therefore possible, by means of the burning mirrors just mentioned, to carry inflammation to a given distance. Those who have made mention of the mirrors constructed by the divine Archimedes, have not said that he made use of a single burning mirror, but of several; and I am of opinion that there is no other way of carrying inflammation to any distance."

Leonhard Digges.

These testimonies are certainly very favourable, and the subject has been still further explained and illustrated by the labours of succeeding inquirers. About the end of the sixteenth century we find mention of a burning glass on the plan of that of Archimedes, in a work by our countryman Leonhard Digges, entitled *Pantometria*, published in London in 1571, and republished by his son Thomas Digges in 1591. In the preface to the second edition the latter observes, "Archimedes also (as some supposed), with a glasse framed by revolution of a section parabolicall, fired the Roman nauie in the sea, comming to the seige of Syracusa. But, to leaue these celestial causes, and things done of antiquitie, long agoe, my father hath at sundrie times, by the sunne beams, fired powder and discharged ordnance *half a mile* and more distante; which things I am the boulder to report, for that there are yet liuing diuerse of these his doings (*oculati testes*, eye-witnesses), and many other matters far more strange and rare, which I omit as impertinent to this place."

In the twenty-first chapter of the first book, the subject of burning glasses is resumed. "Some have fondly surmised that Archimedes burned the Roman nauie with a portion of a section parabolical, artificiallye made to reflect and unite the sunne beames a great distance off; and for the construction of this glass, toke great peins with high curiositie. to unite large and many intricate demonstrations; but it is a mere fantasie, and utterly impossible with any one glass, whatseuer it be, to fire any thing only one thousand paces off, no, though it were an 100 foote over; marry true it is, the parabola, for his small distance, most perfectly doth unite beames, and most uehemently burneth, of all other reflecting glasses. But how by application of mo glasses to extend this unitie or concourse of beames in his full force, yea to augment and multiply the same, that the farder it is carried the more violently it shall pearse and burne. *Hoc opus hic labor est*, wherein God sparing life and the time which opportunitie serving, and minde to impart to my countrymen some such secrets, as hath, I suppose, in this our age been reueled to very few, no lesse seruing for the securitie and defence of our naturall countrey, than surely to be maruailed at of strangers."

Napier of Merchiston.

A few years after the publication of the *Pantometria* of Leonhard Digges, our illustrious countryman Baron Napier of Merchiston drew up a list of "Secret inventions, profitable and necessary in these days for the defence of this island, and withstanding of strangers, enemies of God's truth and religion." The first and second of these inventions are burning mirrors, which are very briefly described in the following words:—

First, "The invention, proof, and perfect demonstration, geometrical and algebraical, of a burning mirror, which receiving of dispersed beams of the sun, doth reflect the same beams altogether united and concurring precisely in one mathematical point, in the which point most necessarily it engendereth fire; what an evident demonstration of their error who affirm this to be made a parabolic section. The use of this invention serveth for the burning of the enemy's ships, at whatsoever appointed distance."

Secondly, "The invention and sure demonstration of another mirror, which receiving the dispersed beams of any material fire or flame, yieldeth also the former effect, and serveth for the like use."

It does not appear that Napier ever condescended to give any further account of these burning mirrors; for when he was solicited a short time before his death, by one of his most particular friends, "not to bury such excellent inventions in the grave with him," he replied, "that for the ruin and overthrow of man there were too many devices already framed, which, if he could make to be fewer, he would with all his might endeavour to do; and that therefore seeing the malice and rancour rooted in the heart of mankind will not suffer them to diminish the number of them, by any new conceit of his they should never be increased."

Labours of Kircher.

The next author whom we find treating on the subject of the burning glasses of Archimedes, is the learned and indefatigable Kircher, whose zeal we have already mentioned as having led him to Syracuse to examine the practicability of the project on the spot, and who besides investigated the subject by a great variety of experiments. "He began with combining a number of parabolic specula; but this method was quickly abandoned, and he resorted to the use of plane mirrors. Having procured a number of plane and circular glasses, he placed them upon a wall, at such degrees of inclination that they all reflected the light of the sun to one point, and produced a considerable heat. His principal experiments, however, were made with five plain specula fixed in a frame, so that they collected the solar rays at the distance of more than one hundred feet. At this distance he produced a degree of heat which sufficiently convinced him, that by increasing the number of his mirrors, he could have consumed inflammable substances at a much greater distance. He informs us in his *Magica Catoptrica*, that the heat of the first reflection was different from that of direct light; that the light, when doubled, gave a very preceptible increase of heat; that it had the heat of a fire when tripled; that when quadrupled, the heat could still be endured; but that a five-fold reflection made the heat almost intolerable. From these results he concludes that a combination of plane mirrors was capable of producing more powerful effects than mirrors of a parabolic, hyperbolic, or elliptic form; and he entreats future mathematicians to prosecute the subject with a more numerous combination of plane specula."

Of Buffon.

But of all the authors who have laboured in this curious speculation, Buffon is the one who has thrown the clearest light on the subject; and, by the ingenuity, extent, and multiplicity of his experiments, has left little further to be accomplished by succeeding philosophers. Being soon convinced, like his predecessors, of the utter inefficiency of single mirrors, he then tried by experiment the powers of different plane surfaces in reflecting the sun's light, and found that glass, somewhat carefully polished and silvered behind, reflected more powerfully than the best polished metals, better even than what is employed for the specula of telescopes. He next found, by letting the direct light of the sun into a darkened room, and comparing it there with the reflected light from glass, that it only lost one half by reflection, which he judged of by causing one reflected light to cover another, when the two seemed together equal to the direct light. Thirdly, having received, at distances of one hundred, two hundred, and three hundred feet, the same reflected light from large glasses, he found it had lost almost nothing of its intensity by the thickness of the mass of air which it had traversed. Having established these preliminary facts, he then tried what the effect would be of receiving the image of the sun from different glasses at still greater distances; and a curious fact was observed, namely, that whatever

Loss of light by reflection.

Burning Glasses.

Round form of all distant images.

shape the glass might be, whether square or triangular, or any other, the same was the figure of the reflection at short distances: but as the distance increased, the figure became rounded at the angles; as the distance increased, the rounding of the angles increased along with it, until at last the square or triangular figure was changed into one nearly circular, whatever was the original figure of the glass. This effect Buffon justly ascribed to the circumstance of the apparent magnitude of the sun, every portion of the glass reflecting in reality an image of the sun, and the whole reflection being composed of an infinite number of such images, each of which subtended an angle of half a degree. At small distances, therefore, the images are too small in proportion to the magnitude of the figure to affect the shape. As the distance increases, the magnitude of each of the images increasing along with it, while the figure and magnitude of the whole reflection remains in other respects the same, the former becomes at last equal to the latter, and the square or triangular figure is absorbed in that of the circular image of the sun, and every glass comes at last to give nearly the same figure. Hence it followed that the light could be no otherwise enfeebled by distance than as it was diffused by the increasing magnitude of the image. Putting all these circumstances together, Buffon had hopes of being able to burn in this manner at a great distance, by combining a sufficient number of glasses. Still he had doubts; for supposing we wish to burn at two hundred and forty feet distant, the focus or image of the sun at this distance could not be less than two feet. What a diffusion of light, compared with the degree of concentration in very ordinary glasses,—in the mirror of the Academy of Sciences, for instance, of which the diameter is three feet! This was a hundred times larger than the diameter of its focus, which was only one third of an inch; and hence he concluded, that to burn as powerfully at two hundred and forty feet, the diameter of the mirror would have required to be two hundred and sixteen feet, which was impossible. Still, however, he had a suspicion that the effect of a large focus might be greater than the mere effect of concentration, although this was contrary to the received opinion of Descartes and other opticians; and on appealing to actual experiment, he found his suspicions satisfactorily confirmed. On trying, for example, a small burning glass three inches diameter, and the focal distance six inches, and diameter one eighteenth of an inch, with a glass thirty-two inches diameter, and a focus of two thirds of an inch,—in the focus of the latter copper melted in less than a minute, while in that of the former the copper would scarcely be gently heated, according to the principle we have already explained. Encouraged by this experiment, Buffon proceeded to put his plan in execution, and constructed, with the aid of M. Passemant, a compound mirror, represented at fig. 6. This consisted at first of sixty-eight silvered glasses, each eight inches long and six broad, arranged in a square frame parallel to each other, and separated by spaces, about one fourth or one third of an inch. These allowed the glasses to move easily independent of one another, and also allowed the operator to see through and to direct the reflections to one point. In this manner the whole sixty-eight mirrors could be made to unite their force at twenty, thirty, or even a hundred and fifty feet; and by augmenting the size of the compound mirror by adding to the number of small mirrors, the effect might be increased to any extent. The only difficulty consists in moving such a number of glasses, and directing them all to the same object. Great attention must also be paid to the choice of the glasses, which are often very defective, though they may appear well enough at first sight. The sixty-eight above described had to be picked out of more than five hundred. They were tried by observing the reflection on a wall a hundred and fifty feet distant, and those only which gave distinct and well-defined images were taken.

Effect of large focal image.

Compound mirror.

Effects of mirror.

The first experiment was made with the mirror on the 23d of March 1747, at mid-day. With forty glasses only, it set fire to a plank of tarred beech. Not being yet mounted, however, on its stand, it acted under a great disadvantage

The same day, a plank done over with tar and brimstone was set fire to at a hundred and twenty-six feet with ninety-eight glasses, the mirror being still more disadvantageously placed.

On the 3d of April, at four o'clock in the afternoon, the mirror being mounted and placed on its stand, a slight inflammation was produced on a plank covered with shreds of wool at a hundred and thirty-eight feet distance, with a hundred and twelve glasses, although the sun was weak, and the light very pale. One requires to take care of himself in approaching the place where the combustible materials are placed, and avoid looking at the mirror; for if unfortunately the eyes are found in the focus, they would be struck blind by the brightness of the light.

On the 4th of April, at eleven in the morning, the sun being very pale, and covered with vapours and light clouds, the mirror was still capable of producing, with a hundred and fifty-four glasses, at a hundred and fifty feet distance, a heat so considerable, that in less than two minutes it made a tarred plank smoke, which would certainly have been inflamed if the sun had not disappeared all of a sudden. The next day at three P. M., with the sun still more feeble than the preceding, chips of fir coated with sulphur and mixed with charcoal were kindled in less than a minute and a half, with a hundred and fifty-four glasses, at the distance of a hundred and fifty feet. When the sun was brisk it only required a few seconds to produce inflammation.

On the 10th of April, after mid-day, with the sun pretty clear, a plank of tarred fir was kindled at a hundred and fifty feet with only a hundred and twenty-eight glasses; the inflammation was very sudden, and extended over the whole breadth of the focus of sixteen inches diameter. The same day at half-past two the light was directed on a plank of beech tarred in part and covered in some places with shreds of wool. The inflammation was very quickly produced; it commenced with those parts of the wood that were uncovered, and the fire was so violent that it was necessary to immerse the plank in water to extinguish it: there were a hundred and forty-eight glasses, and the distance was a hundred and fifty feet.

On the 11th of April, the focus being only twenty feet distant from the mirror, twelve glasses only were required to inflame little combustible matters. With twenty-one glasses a plank of beech which had been already partly inflamed was set fire to; with forty-five glasses a large flagon of tin, weighing about six pounds, was melted; and with a hundred and seventeen glasses thin pieces of silver were melted, and an iron plate made red hot; and "I am persuaded," says he, "that at fifty feet distant the metals might have been melted as well as at twenty, by employing all the glasses of the mirror; and as the focus at this distance is six or seven inches diameter, it affords a very convenient method of making experiments on the metals, which could not be done with ordinary mirrors, the foci of which are either of feeble power, or a hundred times smaller than that of mine. I remarked that the metals, and particularly silver, smoked much before melting; the smoke was so sensible as to cast a shade on the ground. This I particularly observed, for it was not possible to look at the metal in the focus, the light being much brighter than that of the sun."

Such are the results of Buffon's original experiments, and they are certainly very remarkable, and such as could not have been well anticipated from any previous knowledge of the subject. We have already seen that, according to Professor Leslie's experiments, the greatest heat of the sun in our latitude is 16°; suppose that in France it may amount to 15° in the month of April. The heat required to inflame beech or fir coated with tar cannot be estimated at less than 600° or 800°, which would require a concentration of forty or fifty times; and seeing one half is lost by reflection, it would require eighty or one hundred mirrors; and yet we see at the distance of twenty feet beech was inflamed with only twenty-one mirrors, which we should not have calculated to produce a higher temperature than 157°. Silver, again, cannot be melted with less heat than 4500°, or a concentration of 300 times, and requiring, therefore, 600 mirrors; and yet the pieces of it were melted with 117 mirrors.[1] The same effects were observed at greater distances, making allowance for the distance. At 66 feet tarred beech was inflamed with 40 glasses, at 126 feet with 98, and at 150 feet tarred fir was inflamed very suddenly with 128 glasses. It is not easy to determine the exact diminution of effect by distance, so much will depend on the glasses themselves. Were the reflected image to enlarge itself regularly in receding from the glass, and the light to be equally diffused over the image, the calculation would be simple; but this is not the case, seeing there are rays proceeding from every point of the glass parallel to one another, and the effect of which therefore does not decrease with distance. The rays are also more accumulated in the centre than at the extremities of the image. Still, however, a decided diminution must arise from the distance of the object from the mirror; and the above results, therefore, are still far beyond what could have been looked for from so small a number of glasses employed. The cause of these extraordinary effects of the mirrors it is not easy to explain; and the discrepancy does not seem to have occurred to Buffon, nor to any of the succeeding philosophers who have considered the subject. It is certainly, however, very palpable; and either the original estimate of 15° for the natural heat of the sun is too low, which, however, we have no reason to think from other considerations, as well as the acknowledged accuracy of the observer, and his perfect means of observation; or else, what is more probable, the heat accumulates in the heated body in a higher ratio than that of the amount continually flowing in and discharged. The level of a reservoir, as is well known, rises higher than in proportion to the quantity running in, and discharged by a given opening. It rises to a level increasing as the square of the flow; and something of this kind may perhaps occur with the stream of heat. The subject, however, would require a careful examination, and various new experiments made in a more accurate manner than has yet been done. It is much to be regretted that Buffon did not make use of a thermometer to measure the actual heat in the focus of the mirror. We have no doubt that a few observations with this instrument, or still better with Leslie's thermometric photometer, would lead to curious results.

Besides the above experiments, which were made on the first trials of the mirror, a great number of other experiments were afterwards made, which all confirmed the first. Wood was kindled at 200 feet, and even at 210 feet, with the summer's sun, every time the sky was clear; and with four such mirrors it might be done at 400 feet, and perhaps farther. All the metals also, and metallic minerals, were melted at twenty-five, thirty, and forty feet. It took about half an hour to mount the mirror, and to make all the images coincide in one point; but when it is once adjusted it will serve at all times for any particular distance; but if the focus is to be changed, it will take half an hour to do this,—to change, for example, from 100 feet to 150 feet. The above experiments were made publicly in the Jardin du Roi.

The mirror represented in fig. 6 has 360 glasses. The frame is supported on the axis AB, round which it can be turned by means of the rack FG, and the pinion and handle HK. The axis rests on the two uprights AL BM, which are firmly fixed by mortises into the bottom piece OQ, and cross piece *ab*, and steadied by diagonals; the uprights and frame are movable round an upright pillar or axis, the feet being provided with rollers to cause the whole mirror to turn easily round. The upright pillar or axis is fixed in the centre of a broad square base, or sole of wood, which is capable of turning on rollers or castors, and the whole is moved in any direction. Each of the glasses is fixed on a square plate of metal ABCD, fig. 12, movable on an axis CD, which turns on a small frame, seen from behind in fig. 10, and in front in fig. 11: the screw FE pressing against the back of the plate, and the spring L resisting and pressing in the opposite direction, the plate is held firm in its position, and by turning the screw in or out the angle of the glass is altered. The whole frame and plate are besides movable round another axis CD, perpendicular to the former; this motion being regulated and directed by screws and springs in the same manner: and thus the glass having a universal motion, can easily be set so as to throw the reflection in any direction, and all the glasses by the same means directed towards one point or focus.

Effects of Archimedes' mirror still doubtful.

Such are the effects and construction of the celebrated mirror of Buffon, which actually set fire to wood at so considerable a distance; and proves, therefore, clearly the practicability, with such an apparatus, of setting fire to a vessel at the same distance. That it proves, however, the actual fact related of Archimedes, seems to admit of considerable doubts. A distinguished philosopher in the end of the eighteenth century, with all the advantages of the amazing progress of science and the arts up to that period, has, after a laborious research and numerous experiments with all the leisure of philosophical inquiry, at last succeeded in constructing a combination of mirrors, which inflames combustible materials at a distance, and in a convenient situation. But when we consider the low state of the arts in the time of the Syracusan philosopher, the inferior reflecting power of any mirror then in use, the difficulty and expense of procuring such a number as would be necessary, and of combining them together so as to act with facility and effect on an enemy's fleet,—seeing that even in Buffon's apparatus it took half an hour to bring the mirrors to a focus; and, therefore, in the case of a vessel in motion, it would be next to impossible to follow it, and keep all the glasses steadily directed to one point,—if we consider all these circumstances, the difficulties of the undertaking must appear so enormously increased, that it seems to be no disparagement to the genius even of Archimedes to require stronger proof than has yet been adduced to convince us of the fact; and particularly, as Polybius, Livy, and Plutarch, who have described the prodigies of his mechanical skill, are silent in regard to this, which would have been as wonderful as any, and was calculated to excite fully greater astonishment. That Archimedes had conceived such an idea, and perhaps in part reduced it to practice, appears certain from so many concurring testimonies; but that he actually reduced the Roman fleet to ashes, is probably only one of those exaggerations to which every action, in any degree marvellous, naturally gives rise.

Since the time of Buffon scarcely any thing further has

[1] This is Wedgewood's estimate of the melting point of silver, but the more recent investigations of Daniel reduce it to 1873° Fahr.

Burning Glasses.

Peyrard's mirrors.

been done on the subject of these compound burning mirrors; and as the subject is one more of curiosity than of real utility, for, as to its application as an engine of war, it is now out of the question, enough has perhaps been done. In Peyrard's edition of the works of Archimedes, however, there is a memoir on the subject by the translator, who seems to have bestowed a good deal of attention on the subject, and suggested various ingenious improvements on the mode of combining the mirrors, and directing them with facility to any object even though in motion; but he does not seem actually to have constructed any on this plan. To direct and change so many mirrors quickly would require evidently several operators at the same time, as each mirror must be set separately. But it is extremely difficult in the ordinary way for different hands to act in concert, because if any one of the glasses, for instance, were out of the focus, it would be impossible to tell which it was, and each operator would be moving his own, and thus deranging the whole. Peyrard, therefore, proposes to furnish each mirror with a telescope, adjustable in such a manner that, being turned to any object, the reflected rays from the mirror should fall in the same direction. The adjusting apparatus consists of a telescope attached parallel to the sides of the mirror, and also capable of turning on its axis and carrying the mirror round with it. The mirror is besides capable of turning on an axis of its own, perpendicular to that of the telescope, and by this double motion the adjustment is effected. The mirror is first turned on the axis of the telescope until its own particular axis becomes perpendicular to the plane of the incident and reflected rays; and this is done by observing when the shadow of the edge of the frame of the mirror falls on a particular point, marked on an index projecting from the telescope. The mirror is then turned on its own axis until the angle of incidence becomes equal to the angle formed by the mirror and telescope; and this is known by a shadow made through an opening in the silver of the mirror falling on a particular spot in the index. In this manner one operator can adjust all the mirrors intrusted to him with accuracy and facility, and without knowing at all what the others are doing. The apparatus is represented at fig. 7, and the following is Peyrard's description.

Where AB is a common telescope with only one tube, containing the object-glass at B, and the eye-glass at A. The tube is movable on its axis between the two collars CC, C′C′, which are fixed to a piece of metal, DD. This piece of metal is supported on a stand like a common telescope, having a vertical and horizontal motion, by which the axis of the telescope may be directed with facility to any given point. The axis of the instrument is marked out by the intersection of a pair of cross wires placed in the anterior focus of the eye-glass; and when this point of intersection is directed to any object, the whole instrument is kept steady in its place by the screws F and G, the former of which prevents any motion in a vertical direction, and the latter in a horizontal direction. From the middle of the tube AB rises a cylindrical piece of metal M M, and upon the eye-glass extremity a branch of iron HHH, wrought square, is fixed firmly in a direction parallel to the axis of the cylindrical piece MM.

A plane silvered glass mirror IL, inserted into a proper frame, is made to turn on two pivots, one of which, *m m*, rests on the cylinder MM, while the other, *o o*, is inserted in the horizontal part of the branch HH. The straight line which passes through the centre of these pivots must be exactly parallel to the silvered back of the mirror, and at right angles to the axis of the telescope, and the black mark N, produced by a scratch upon the silvered surface, must be bisected by the axis of the mirror.

Above the object end B of the tube is fixed a plate of metal, seen in the figure; and behind this plate is seen another square plate, *z z*, on which are shown the lines *x x*, *y y*, crossing each other at right angles. By means of a piece of brass fixed to the last of these plates, and traversing a square hole made in the other plate, the square plate may be moved up and down, and from right to left; and it is kept in any position which is thus given to it, by a screw on the back of the fixed plate. The movable square plate must be adjusted in such a manner that the line *x x* may intersect the axis of the telescope, and be parallel to the axis *o m* of the mirror. The position of the line *y y* must also be such that its distance from the axis of the telescope is equal to the distance of the line IK from the same axis. When the plate *z z* is thus adjusted, the straight line *y y* will always be in the same plane with the line IK, whatever may be the position of the mirror; and a line drawn from a point at N, where the axis of the mirror cuts IK, to the point where *y y* intersects *x x*, will be parallel to the axis of the telescope.

The spring QQ′ is fixed at Q to the arm HH, and by a screw R working into its other extremity Q′ the end H of the horizontal arm may be made to press the pivot *o o* upon the frame of the mirror. The horizontal branch HH, which is represented separately in fig. 10, is surrounded with several pieces. The piece *d b* and pivot *o* are fixed in an invariable manner. The pivot *o o* is inserted in a square hole through the piece VV, and through the extremity of the arm HH. The piece *d b* may be moved either before or behind by turning the screw; and the piece VV may be moved from right to left with the piece *d b* by means of the screw S.

The apparatus being thus constructed, the next thing to be considered is the method of adjusting it. In order to effect this, the axis of the mirror must be perpendicular to the axis of the telescope; the line drawn from a point near N, where the axis of the mirror cuts the line IK, to the point of intersection of *x x* and *y y*, must be parallel to IK, and the straight line *y y* must always be in the same plane with IK.

The mirror is first placed in such a manner that the line IK is at right angles to the axis of the telescope. By turning the screw I, the lower edge of the frame is made a tangent to the circular surface MM′, which is parallel to the axis of the telescope. The screw I is then turned in order to fix the piece *d b* in an invariable manner.

The axis of the telescope is next directed to a point on a plane surface placed at a certain distance. This point must be situated in a vertical plane, perpendicular to the plane surface, and passing through the eye of the observer and the centre of the sun. A horizontal line being drawn through this point, a second point is taken, as far from the first as the centre of the mirror is distant from the axis of the object-glass. By unscrewing S, turning the telescope on its axis, and the mirror also about its own axis, the piece VV is moved backwards or forwards until the centre of the reflected image falls upon the second point. The square plate *z z* is then adjusted in such a manner that the shadow of the line IK falls on the line *y y*, and that the shadow of NN is bisected by the line *x x*. When this happens, the plate *z z* is firmly fixed. Hence it follows that whenever this adjustment is made, and when the intersection of the cross wires of the telescope is directed to any point, the rays reflected by the mirror will be parallel to the axis of the telescope, and will always continue so while the shadow of IK falls on *y y*, and while the shadow of NN is bisected by *x x*.

In making use of the mirror, the intersection of the cross wires must be first directed to any point of the ob-

Burning Glasses.

ject which is to be inflamed. The telescope must next be turned round in the collars CC, C′C′, till the shadow of the line IK falls upon *y y*; and finally, the mirror must be turned about its own axis till the shadow of NN is bisected by the line *x x*. The centre of the reflected image will consequently fall upon a point of the object as far distant from the point to which the intersection of the wires was directed, as the centre of the mirror is from the axis of the telescope. The image may obviously be preserved in this position as long as we choose, by keeping the shadow of IK and N in the same position.

Calculation of Peyrard.

The above apparatus is certainly well contrived for effecting its object, but seems at the same time rather complex and expensive for any purpose to which such a mirror might be required. In regard to the power of such a combination of mirrors, M. Peyrard has only made some calculations founded on the observations of Buffon. In the first place, in regard to the effect of the distance of the mirrors from the object, he calculates that, with one about eighteen inches diameter, the rays are so diffused as to reduce the heating effect to one half at 66 feet; to one third at 118 feet; to one fourth at 161 feet; to one fifth at 200 feet; and to one tenth at 348 feet. The next question is to determine, at the shortest distance from the glass, how many times the sun's heat must be multiplied by the glasses to produce inflammation, or boiling or fusing of metals, or any other similar effects, in order to calculate how many glasses would be sufficient for the purpose, such reflection being, as Buffon found, one half of the sun's heat. This question is solved by Peyrard, from the observations of Buffon already stated, allowing for the distances by the above rule, and reducing them all to the shortest, or when the object is placed as close as possible to the glasses. Hence he finds, that on the 23d March, calculating for the number of glasses and the distance, four times the heat of the sun would set fire to a plank of tarred beech, and $4\frac{1}{12}$ times to a plank coated with tar and sulphur; *2dly*, that on the 10th of April a plank of tarred fir was set fire to by $4\frac{4}{15}$ times the sun's heat; *3dly*, on the 11th of April a plank of beech which had been already on fire was inflamed by $5\frac{1}{4}$ times the sun's heat. The same day small combustible materials were inflamed with three times the sun's heat, and also a block of tin weighing six pounds was melted by $11\frac{1}{4}$ times the sun's heat; also thin pieces of silver were melted, and a plate of iron made red hot, by $29\frac{1}{4}$ times the sun's heat; and Peyrard on the whole draws the conclusion, in the view of setting fire to a fleet of ships, that five times the heat of the sun would be sufficient to inflame tarred planks, and eight times this heat would be sufficient to inflame all sorts of wood, and less in general would do it. Hence he deduced, in regard to distance, that sixteen of these glasses would be sufficient to inflame wood at the distance of 66 feet; twenty-four at 118 feet; thirty-two at 161 feet; forty at 200; eighty at 348; and at 3750, or nearly three quarters of a mile, it would require 590.

In regard to these calculations, and particularly that of the effect of the sun's heat, it appears so much beyond what might naturally be looked for, that its accuracy may well be questioned; and it is surprising this should have escaped the notice of the author, and of succeeding writers, who have copied without comment all these results. If four times the sun's heat be sufficient to inflame wood, then eight glasses would do it at a small distance, which is hardly credible. At any rate, if it be so, it implies an accumulation of heat which is quite unaccountable on any of the usual principles on which this fluid acts. In fact, we have already seen, from the observations of the photometer, that the greatest effect of the sun's heat in our latitude does not exceed sixteen degrees. Supposing this the amount of it in France in the month of April, four times this would only be sixty-four degrees, while the heat of inflammation cannot be less than 800°, twelve times what Peyrard supposes. Again, thirty times the sun's heat would only amount to 480°; and yet he says that silver was melted with this heat, which requires a temperature of 4500°, nearly ten times as much. We have already stated and explained how much the effects of Buffon's mirrors exceed what might reasonably be expected from their concentrative power. But these calculations carry them still farther. The difference seems to arise from the principle on which Peyrard has calculated the effect of distance. He supposes it to diminish as the square of the distance from a point situated so far behind the mirror, that the latter subtends at that point the same angle with the sun, as at fig. 9, where AB is the diameter of the glass, AG and BG two lines, one from each extremity of the glass, and forming together an angle, AGB, of 32′. These lines being prolonged, indicate the boundary of the extreme rays reflected from the glass; and the sections MI ON RS of the cone diminish as the square of GD GP and G. In this view it would be the same as if all the light proceeded from the point G, so that all the rays would diverge from it. This, however, is far from being the case, as all the rays which fall on the glass from any given point of the sun are reflected in lines sensibly parallel, which do not diverge from that or any other point, and cannot therefore suffer diminution from distance. This calculation, therefore, would require considerable modification; and the whole subject would require, as already stated, to be re-examined experimentally.

Single reflectors.

Such are the compound mirrors which have been made on the principle of that of Archimedes. In regard to single concave mirrors, a great many of these have been constructed at different periods, remarkable for their powerful effects. We shall just describe some of the principal ones. M. Vilette, a French artist at Lyons, constructed no fewer than five mirrors of this kind, of considerable magnitude. One of them was bought by M. d'Alibert for 1500 livres; another was purchased by Tavernier, and presented to the king of Persia; a third was sent by the French king to the Royal Academy; a fourth was bought by the king of Denmark; and the fifth was brought to England for public exhibition. The first of these mirrors was thirty inches in diameter, and weighed above a hundredweight. Its focal length was about three feet, and the size of the sun's image was about half a louis d'or. It was mounted on a circular frame of steel, and could easily be put into any required position. This mirror was made in 1670, and having been brought to St Germains by order of the king, his majesty was so well pleased with it, that he rewarded Vilette with a hundred pistoles for the sight of it, and afterwards purchased it and placed it in the Royal Observatory of Paris. The effects were the following:

Vilette's burning mirrors.

	Seconds.
A small piece of pot iron was melted in	40
A silver piece of fifteen pence was pierced in	24
A thick nail (*le clou de paysan*) melted in	30
The end of a sword blade of Olinde burnt in	43
A brass counter was pierced in	6
A piece of red copper was melted in	42
A piece of chamber quarrystone was vitrified in	45
Watch-spring steel melted in	9
A mineral stone, such as is used in harquebusses *à rouet*, was calcined and vitrified in	1
A piece of mortar was vitrified in	52

Green wood and other bodies took fire instantly.

The mirror of M. Vilette which was brought to England was put into the hands of Dr Harris and Dr Desaguliers, who made several trials with it. It was a composi-

tion of copper, tin, and tin glass; and its reflection had something of a yellow cast. There were only a few small flaws in the concave surface, but there were some holes in the convex side, which was polished. The diameter of the mirror was 47 inches, its radius of curvature 76 inches, and its focal length 38 inches. The following results were obtained in June 1718, between nine and twelve o'clock in the morning, and the time was measured by a half-second pendulum.

	Seconds.
A red piece of Roman patera began to melt in	3
and was ready to drop in	100
A black piece of the same melted in	4
and was ready to drop in	64
Chalk taken out of an echinus spatangus filled with chalk only fled away in	23
A fossil shell calcined in	7
and did no more in	64
The black part of a piece of Pompey's pillar melted in	50
and the white part in	54
Copper ore, with no metal visible, vitrified in	8
Slag or cinder of the iron work said to have been wrought by the Saxons was ready to run in	29½

The mirror now became hot, and burned with much less force.

	Seconds.
Iron ore fled at first, but melted in	24
Talc began to calcine at	40
and held in the focus	64
Calculus humanus was calcined in	2
and only dropped off in	60
The tooth of an anonymous fish melted in	32½
The asbestos seemed condensed a little in	28

But it now became cloudy. M. Vilette says that the mirror usually calcines asbestos.

A golden marcassite broke, and began to melt in	30
A silver sixpence melted in	7½
A King William's copper halfpenny melted in	20
and ran with a hole in it in	31
A King George's halfpenny melted in	16
and ran in	34
Tin melted in	3
Cast iron melted in	16
Slate melted in	3
and had a hole in	6
Thin tile melted in	4
and had a hole and was vitrified through in	80
Bone calcined in	4
and vitrified in	33

An emerald was melted into a substance like Turquoise stone, and a diamond that weighed 4 grains lost $\frac{7}{8}$ths of its weight.

This mirror was made by M. Vilette some years after the first, and with the assistance of his two sons. It came into the possession of M. Vilette the son, engineer and optician to his electoral highness of Cologne, bishop and prince of Liege, where he commonly resides. At the desire of several learned men, M. Vilette brought it to London, where its effects were exhibited in Priory Garden, Whitehall.

Maginus and Manfredi. Large burning mirrors were made by Maginus, and by Manfredi, canon of Milan, one twenty inches diameter, and the other three and a half feet; but, from the accounts of them in the *Philosophical Transactions*, they appear to have had but a feeble power compared with those of Vilette.

Garouste's mirror. In the year 1685 M. de la Garouste presented to the Academy of Sciences a large metallic mirror, five feet two inches in diameter, and five feet in focal length. It was not equally polished, and a piece was inserted in the middle of it where the metal had failed. This circumstance, however, did not seem to diminish its force. Several trials were made with this mirror in the academy, by order of M. de Louvois, but the precise effects which it produced have not been detailed. It is merely stated that those who tried it were satisfied with the results, and that its effects would have been much greater had it been better polished, and mounted upon a proper stand.

Smethwick's mirror. On the 27th of February 1667–8, Francis Smethwick, Esq. produced before the Royal Society two burning concave glasses, ground of a *newly invented figure*, which was probably that of a parabola. One of them was six inches diameter, with three inches of focal length; and the other was of the same diameter, with its focus ten inches distant. When these were brought towards a large lighted candle, they somewhat warmed the faces of those that were four or five feet distant; and when held to the fire, they burnt gloves and garments at the distance of about three feet from the fire. At another experiment made in the presence of Dr Seth Ward, the deeper of the two burned a piece of wood into flame in the space of ten seconds, and the shallower one in five seconds. This experiment was made in autumn, at nine o'clock in the morning, when the weather was gloomy. By exposing the deeper concave to a northern window on which the sun did not shine, it was found to warm the hand by "collecting the warmed air in the day time, which it would not do after sunset."

This last effect is extremely remarkable; it must have arisen from the mirror collecting the radiations of heat from the distant atmosphere warmed by the heat of the day. The existence of these radiations was then perfectly unknown, and not suspected, indeed, until they were discovered only a few years ago by Professor Leslie, and actually measured by the ethrioscope.

The burning mirror to which we have already alluded, made by the celebrated Tschirnhausen, was formed of thin copperplate, about one sixteenth of an inch thick. According to one account it was about three Leipsic ells, equal to five feet diameter, and burnt at the distance of three feet and a half. According to another its diameter was four feet and a half, and its focal distance twelve feet.

The following are its effects:—

1. A piece of wood held in the focus flames in a moment, so that a fresh wind can hardly put it out.
2. Water applied in an earthen vessel immediately boils; and the vessel being kept there some time, the water evaporates all away.
3. A piece of tin or lead three inches thick melts away in drops as soon as it is put in the focus; and when held there a little time is in a *perfect fluor*, so that in two or three minutes it is quite pierced through.
4. A plate of iron or steel becomes immediately red hot, and soon after a hole is burnt through it.
5. Copper, silver, &c. melt in five or six minutes.
6. Stones, brick, &c. soon become red hot.
7. Slate becomes red hot, but in a few minutes turns into a fine sort of black glass.
8. Tiles which had been exposed to the most intense heat of fire melt down into a yellow glass.
9. Pot-shreds that had been much used in the fire melt into a blackish yellow glass.
10. Pumice stone melts into a white transparent glass.
11. A piece of a very strong crucible melted into a glass in eight minutes.
12. Bones were converted into a kind of opaque glass, and a clod of earth into a yellow or greenish glass.
13. The beams of the full moon when at her greatest altitude were concentrated by this speculum; but no perceptible degree of heat was experienced.

A plan for constructing burning mirrors of wood gilded

over was proposed by Zacharias Quabenus, in his work *In Nervo Optico*. They were joined in twenty, or even a hundred concave pieces, on a turned wooden dish or scuttle, and the surface coated with pitch and gilded.

Neuman mirror.

It is possible to construct mirrors of still more slender materials; and Zahnius, in his work *In Oculo Artifico*, fundam. 3, states, that an engineer of Vienna of the name of Neuman formed burning mirrors of pasteboard, covered in the inside with straw glued to it: and that they were capable of melting metals almost instantly. It is evident from what we have stated, that mirrors of this kind, from the great surface exposed, and the concentration in a perfect form not being absolutely necessary, may produce very powerful effects.

Hoesen and Ehrard's mirrors.

Parabolic mirrors of a large size and very considerable power were constructed by M. Hoesen of Dresden, and afterwards by M. Ehrard. These mirrors were composed of several pieces of solid wood, and on the convex part were pieces of wood, both diverging from the vertex and transversely, nicely fitted and strengthened. The concave part of this framing was covered with copperplate one eighth of an inch in thickness, four and a half feet long, and two and a half feet broad, so as to resemble one piece finely polished. The speculum was so supported as to be easily managed, and the anterior part of it was subtended by an iron arch half an inch thick. The middle of this arch, which coincided with the place of the burning focus, was perforated into a ring, which supported from both sides an iron fork for receiving the body to be examined. Four of M. Ehrard's mirrors constructed in this way had the following dimensions:—

	Perimeter.		Diameter or Ordinate		Depth or Absciss.		Focal Length.	
	Feet.	Inches.	Feet	Inches.	Feet.	Inches.	Feet.	Inches
No. 1	29	4	9	7	1	4	4	0
2	21	0	6	8	0	$10\frac{1}{2}$	3	1
3	16	4	5	1	0	$10\frac{1}{2}$	1	10
4	13	$2\frac{1}{2}$	4	2	0	7	1	9

The celebrated Wolfius, who had witnessed the effects of these mirrors, states that in burning, calcining, melting, and vitrifying, they far exceeded any thing of the kind ever known. The hardest stones scarcely resisted a few seconds. Metals were rapidly perforated, and vegetables and bones were immediately burnt to a cinder and vitrified.

Dr Gregory's burning mirror.

Our celebrated countryman Dr James Gregory turned his attention to the construction of burning machines about the year 1670; and in a letter to Mr Collins, dated St Andrews, 7th March 1673, he states his views on this subject, and requests Mr Collins to communicate them to Sir Isaac Newton, who returns a favourable opinion of the invention in a letter to Mr Collins. The passages in these letters are too interesting to be given in any other form than in the original words of these distinguished authors.

"Mr Newton's discourse of reflection," says Dr Gregory, "puts me in mind of a notion I had of burning glasses several years ago, which appears to me more usefull than subtile. If ther be a concave speculum of glasse, the leaded convex surface having the same center with the concave, or to speak preciselie, albeit perchance to little more purpose, let the radius of the convexitie be c, the thickness of the glasse *in axis transitu* f, the radius of the convexitie equal to $\frac{9c^2+18cf+5f^2}{9c+f}$, this speculum sal have the *foci* of both the surfaces in the same point; and not onlie that, but all the rays which are reflected betwixt the two surfaces, sal, in their egresse, come, *quam proximé*, to the common focus. The making of such an speculum requireth not much more airt than an ordinar plane glasse, seing great subtiltie is not necessar here; so that I believe they who mak the plane miroir glasses, wold mak one of these, three foot in diameter, for four or five pounds sterling, or little more: for I have seen plane glasses, almost of that bignes, sold even here for less money. Now seing (as Mr Newton observeth) that al reflecting metalls lose more than one third of the rayes; this concave glasse, even *cæteris paribus*, wold have an great advantage of a metall one; for certainlie an exactlie polished thin miroir glasse, of good transparent mater, after a few reflections, doeth not lose one fourth of the rayes; and, upon other accounts, this hath incomparable advantages, seeing it is more portable, free from tarnishing, and, above al, hardlie $\frac{1}{20}$th of the value. The great usefulness of burning concaves, this being so obvious, and as yet (for quhat I kno) untouched by anie, makes me jcalous that there may be in the practice some fallacie. Ye may communicate this to intelligent persons, and especiallie to Mr Newton; assuring him that none hath a greater veneration for him, admiring more his great and subtile inventions, than his and yours.

"P. S. If ye please, let me hear, with the first convenience, what may be judged the result of this burning concave; for I am as much concerned to be undeceived, if ther be any insuperable difficultie, as to be informed of an most surprising success. I have spoke of it to severals here, but al were as ignorant of it as my self," &c.

Sir Isaac Newton's reply to Mr Collins is dated Cambridge, April 9th, 1673, and contains the following passage:—

"The design of the burning speculum appears to me very plausible, and worthy of being put in practice. What artists may think of it I know not; but the greatest difficulty in the practice that occurs to me, is to proportion the two surfaces so that the force of both may be in the same point according to the theory. But perhaps it is not necessary to be so curious; for it seems to me that the effect would scarce be sensibly less, if both sides should be ground to the concave and gage of the same tool," &c. &c.

Sir Isaac Newton's mirrors.

The attention of Sir Isaac Newton being thus accidentally directed to the subject of burning instruments, he procured seven concave glass mirrors, each of which was eleven and a half inches in diameter, and six of these were placed round the seventh, and contiguous, but so as to have one common focus. The general focal length was twenty-two inches and a half, and about an inch in diameter. It melted gold in about half a minute, and vitrified brick or tile in one second. The effect of these speculæ was obviously much less than seven times the effect of any one of them. The rays of the sun could fall perpendicularly only on the one in the middle; and, in consequence of this obliquity of incidence, none of the speculæ intercepted a column of rays of the same diameter, and the image formed in the focus of each could not be exactly circular.[1]

Zeiher's mirrors.

Burning mirrors composed of glass were constructed by

[1] No account of this burning glass of Sir Isaac Newton's is given in the *Philosophical Transactions*; and we are informed, upon very good authority, that no such instrument is in the possession of the Royal Society. Mr Derham, however, a fellow of the Royal Society, gives the same account which we have followed in the text. (See Derham's *Astrotheologia*, lib. vii. cap. i. note.)

M. Zeiher of St Petersburg. His object was to convert plates of plain glass into concave mirrors, which he effected by placing the glass upon a convex tool, and exposing it to a strong heat, till it assumed the exact curvature of the tool. Zeiher made numerous trials with plates of various sizes, and, after several failures, he succeeded in finding the proper method of conducting the operation. No particular difficulties occurred in giving the proper shape to plates five or six inches in diameter; but, in forming one of sixteen inches, the circumference was moulded to the tool before the central parts, where a number of vesicles of air had collected; and, in some other cases, the glasses cracked after they had received the proper shape. The following method is that which Zeiher always found to succeed:—

A small bit of the glass to be used must first be exposed to the fire till it becomes red hot, and if, after cooling, it has preserved its polish and transparency, the glass is fit for the required purpose; for it sometimes happens that the glass becomes quite black after the operation. The plate of glass is next placed on a concave iron dish of the required curvature, and put into a furnace. Coals are placed below and above the dish, and on all sides of it. The greatest care must then be taken that the glass shall become equally hot both at the circumference and at the centre; for if the red colour should get deeper in the middle, the glass will be in great danger. As soon as the whole is red hot, the instant of its bending to the shape of the mould must be carefully watched; and when this happens, which may be observed from the reflected images of the surrounding coals, all the fire must be removed from above the glass, and also a great part of the fire at its sides. The glass must then be covered with warm ashes, that have been passed through a sieve, and it must be allowed to cool gradually. It is of the utmost importance to mark the precise moment when the glass applies itself to the surface of the mould; for, if it remain too long, a part of the scoriæ which separates from the mould will adhere to the glass. When the glass is covered with the hot ashes the fire must still be allowed to remain below the mould, lest the glass should crack by being cooled too suddenly. When the glass is taken from the furnace, its convex sides may then be silvered for a burning speculum; or, if a lens is required, two of the pieces of glass may be joined, so as to contain a fluid.

M. Zeiher also constructed burning glasses by making a concave frame of wood, and covering the concave surface with a paste made of flour, chalk, &c. till it had the requisite degree of curvature. A number of pieces of silverized glass mirrors, about half an inch square, were then fixed upon the concave side, so as to constitute a polygonal reflecting surface.

Buffon's mirrors of bended plates.

Buffon also, besides the experiments already related, made a good many on the bending of flat plates into a curve. He took circular plates of glass about eighteen inches, two feet, and three feet, in diameter, and having perforated them at the centre with an aperture two or three lines in diameter, he placed them in a circle of iron that was truly turned. A very fine screw, connected with a box stretching across the back of the glass, passed through the hole in the centre into a nut on the other side, so that by turning the screw the circular piece of flat glass was gradually incurvated till it formed a concave mirror. The glass of three feet diameter, when it was bent about five eighths of a line, had its focus fifty feet distant, and set fire to light substances; when it was bent two lines, it burned at the distance of forty feet; when it was bent two and three-fourth lines, its focal length was thirty feet; but in attempting to reduce its focal length to twenty feet, it was broken in pieces. The glass of two feet diameter shared the same fate; but the one of eighteen inches, which had a focal length of twenty-five feet, was preserved as a model of this species of mirror. The accident which happened to the two largest of these mirrors appears to have been owing to the perforation in the centre. In order to remedy this evil, Buffon proposed to place a circular piece of glass at the extremity of a cylindrical drum, made of iron or copper, and completely air tight. The cavity being exhausted by means of an air-pump, the glass at one extremity would be pressed in by the weight of the atmosphere, and would have its focal length inversely proportional to the degree of refraction. This contrivance is represented in fig. 1, Plate CLIII., and also a section of it.

A still more simple and ingenious method of exhausting the air in the drum was contrived by Buffon. He proposed to grind the central part of the plain glass into the form of a small convex glass, and in the focus of this convex portion to place a sulphur match, so that when the mirror was directed to the sun, the rays concentrated by the convex portion would inflame the match, which, being set on fire, would absorb the air, and thus produce a partial vacuum, and consequently an incurvation of the plain glass.[1] See fig. 2.

Mirrors of this kind, with a movable focus, were regarded by Buffon as of great use for measuring the effects of the solar rays, when concentrated into foci of different sizes. As the quantity of incident light and heat is nearly the same to whatever curvature the glass is successively bent, we might thus determine the size of focus by which a maximum effect was produced.

Buffon likewise made a number of concave mirrors by bending plates of glass on moulds of a spherical form. Some of these were as large as three, four, four feet six, and four feet eight inches, in diameter; but the utmost care is requisite in the formation of those of such a large diameter. After these glasses were moulded to the proper shape in appropriate furnaces, their concave and convex sides were carefully ground so as to be perfectly concentric, and the convex side was afterwards silvered by M. de Bernieres. Out of twenty-four mirrors of this kind which Buffon had moulded, he was able to preserve only three, the rest having broken, either by exposure to the air, or in the operation of grinding. One of these three, which was forty-six inches in diameter, was presented to the king of France, and was regarded as the most powerful burning mirror in Europe. The other two were thirty-seven inches in diameter, and one of them was deposited in the Cabinet of Natural History in the Jardin du

[1] Instead of grinding the central part of the glass plate into a convex form, Zeiher proposes that a small burning glass should be applied to inflame the sulphur; or, what is still better than either of these plans, a convex lens might be fastened, by the balsam of Tolu, or any transparent cement, to the centre of the glass plate.

M. Zeiher employed a more effectual method of bending circular plates of glass than that which was used by Buffon. The circular piece of glass was placed in an iron ring, across which was fixed a thin piece of iron, with a hole containing a female screw, so placed as to be above the centre of the glass. A strong bar of brass was also placed across the centre of the speculum; and a screw working in the centre of this, and in the female screw already mentioned, pressed the thin iron bar against the glass, and bent it into the proper curvature. A plate of Venetian glass, two lines thick and twenty Rhinland inches in diameter, was bent in this way till it protruded two lines in the middle, so as to have a focal length of fifteen feet, which was a greater curvature in proportion than any of Buffon's. The glass was kept in this state for several days without suffering any injury. (See *Nov. Comment. Petrop.* 1758, 1759, p. 250, note.)

Burning Glasses.

Roi. Buffon concentrated the rays of the moon by means of the mirror of forty-six inches diameter; but, though his thermometer was very sensible, no heat was perceived.

Burning lenses. Tschirnhausen's lens.

In regard to burning lenses, the first of any magnitude were constructed by M. Tschirnhausen. These were compound glasses; the light, after passing through one large glass, being still farther concentrated by a second smaller one. The large glasses were three and four feet in diameter, their focal length was about twelve feet, and the focal image about one and a half inch diameter. The focal image of the smaller glass did not exceed eight lines. The large lens, which weighed 160 pounds, was purchased by the Duke of Orleans, and presented by him to the French Academy. The following are the remarkable effects produced by it:—

1. All sorts of wood, whether hard or green, and even when wet, were burnt in an instant.

2. Water in a small vessel boiled immediately.

3. All the metals, when the pieces were of a proper size, were easily melted.

4. Tiles, slates, delft ware, pumice stone, talc, whatever was their size, grew red and vitrified.

5. Sulphur, pitch, and resins, melted under water.

6. When the metals were placed in charcoal, they melted more readily, and were completely dissipated.

7. The ashes of wood, vegetables, paper, and cloth, were converted into a transparent glass.

8. All the metals were vitrified upon a plate of porcelain. Gold received a fine purple colour.

9. Substances that would not melt in pieces were easily melted in powder; and those that resisted the heat in this form melted by adding a little salt.

10. A substance easily fused assists in melting more refractory substances when placed along with them in the focus; and it is very singular, that two substances which are very difficult to melt separately, are very easily melted when exposed together, such as flint and English chalk.

11. A piece of melted copper being thrown suddenly into cold water, produced such a violent concussion that the strongest earthen vessels were broken to pieces, and the copper was thrown off in such small particles that not a grain of it could be found. This did not happen with any other metal.

12. All bodies except the metals lose their colour. The precious stones are instantly deprived of it.

13. Certain bodies vitrify easily, and become as transparent as crystal; but by cooling they grow as white as milk, and lose all their transparency.

14. Other bodies that are opaque when melted become beautifully transparent when they are cooled.

15. Substances that are transparent both when melted and cold become opaque some days after.

16. Substances which the heat renders at first transparent, but which afterwards become opaque by being melted with other substances that are always opaque, produce a beautiful glass, always transparent.

17. The rays of the moon concentrated by this lens, though extremely brilliant, have no heat.

Buffon's fluid burning lenses.

M. de Buffon, whose ingenuity and research extended themselves into every branch of this subject, constructed various burning lenses of different kinds. His first object was to form burning glasses, by combining two circular segments of a glass sphere so as to form a lenticular cavity to be filled with water. These glass segments were first moulded into their proper shape, and then regularly ground on both sides, so that the concave and convex surfaces were exactly parallel. The one which he constructed was thirty-seven inches in diameter, with a focal length of about five feet and a half; and the segments were of considerable thickness, to prevent them from breaking or altering their form by the weight of the included water. This lens is represented at fig. 3. As the refractive power of water is very small, Buffon proposed to increase it by saturating it with salt; but notwithstanding every precaution, he found that the focus of lenses of this kind was never well terminated, nor reduced to its smallest size, and that the different refractions which the rays sustained produced a very great degree of aberration. Buffon also proposed to make each segment consist of a number of smaller segments put together into a frame; but as the water could not easily be prevented from insinuating itself between the joints of the segments, and as there would be a great difficulty in arranging them in the same spherical circumference, this kind of burning glass does not seem to have ever been executed.

Buffon's lenses with concentric zones.

Having made some experiments on the loss of light in passing through thick glasses, Buffon found it very considerable, so that it detracted greatly from the power of large burning glasses, which must of necessity be proportionally thick in the centre. Bouguer had formerly estimated the loss of light in passing through glass one twelfth of an inch, at two sevenths of the whole. But the glass used by him must have been extremely imperfect; for Buffon found, with glass from St Gobin, the loss of light in passing through one twelfth of an inch, one seventh of the whole, or only half the amount of Bouguer's estimate. Through glass one third of an inch thick, the loss was about two thirds. Hence in very large lenses the central portions must become nearly quite inefficient, from the quantity of light obstructed by them. On considering this subject, Buffon conceived a very ingenious plan for obviating the effect, and which has since become of great importance, from the extensive application of it in France in the construction of the large lenses now used there with such advantage in the light-houses, in place of reflectors. It consisted in forming the lens, not of one mass, but of several detached pieces united together into one. The central portion was a lens of much smaller diameter than the one intended to be formed, not one third perhaps, but having the same focal distance, and being therefore much thinner than the central portion of a whole lens would be; round this a second portion is set, forming a complete zone, and filling up another third of the diameter of the glass; lastly, another similar zone round the second, forming the exterior portion of the lens. Each of these zones forms a portion of a lens of the same focal distance as the central one, only much thinner; and then we obtain a very large lens, and yet extremely thin in proportion, so as to pass a much larger quantity of light than the others. Fig. 4 is a view of one of this sort of lenses, and fig. 5 sections of several lenses, which will render it quite intelligible. This species of glass Buffon considers as the most perfect of the kind; and when it is made three feet diameter, and an inch and a fourth thick at the centre, and six feet focus, he thinks it will give a degree of heat four times greater than that of the most powerful lenses yet known. "I venture to predict," he says, "that this glass in pieces, which I have thought of for twenty years, will be one of the most useful instruments of physics." Instead of having each zone in one entire piece, it is obvious that, without altering the effect, the zones, as proposed by Sir David Brewster, may be composed of two or more pieces, which facilitates the perfect execution; and this is the mode in which they are now constructed in France, constituting one of the most important improvements hitherto made in light-houses. Besides their thinness, these glasses possess other advantages. The pieces which compose the compound ones can be easily obtained, and selected of the purest kind and freest from flaws and veins; whereas in large lenses it was extremely difficult to obtain one entire mass of glass free from impurities and imperfections. The spherical aber-

Burning Glasses.

ration, which is very considerable in large glasses, can here be avoided by making the exterior segments of such focal lengths as to throw the rays to the same point with the central part. Fig. 6 shows a section of one of these lenses, and a view of one of the pieces.

Trudaine's lens.

The next burning lens of any magnitude was constructed by M. Bernieres, for M. Trudaine de Moutigny, an honorary member of the Royal Academy of Sciences. This gentleman, whose liberality and zeal deserve to be recorded, engaged to be at the expense of a large burning glass, formed under the direction of several commissioners named by the academy. This lens consisted of two spherical segments eight feet radius and eight lines thick. The lenticular cavity was four feet in diameter, and six inches and five lines thick at the centre, and was filled with spirits of wine, of which it held no less than 140 pints. The focal length of a zone at the circumference, about six or seven lines broad, was ten feet and six lines, the focal length of a portion at the centre, about six inches in diameter, was ten feet seven inches and five lines, the diameter of the focus was fourteen lines and three fourths. When the whole surface was covered, except a zone at the circumference of six or seven lines, the following were the foci of the different rays:

	Feet.	Inches.	Lines.	
Violet	9	6	4½	from the centre of the lens.
Blue	9	7	10½	
Yellow	10	2	3	
Orange	10	2	10	
Red	10	3	11½	

The following experiments were made in October 1774, in the Jardin de l'Infante, by MM. Trudaine, Macquer, Cadet, Lavoisier, and Brisson, the commissioners appointed by the academy.

1. The burning power of the anterior half of the lens was much greater than that of the exterior half.

2. On the 5th of October, after mid-day, the sky not being very clear, two farthings placed upon charcoal were completely melted in half a minute.

3. In order to melt forged iron, it was found necessary to concentrate the rays by a second lens eight inches and a half diameter, twenty-two inches eight lines in focal length, and placed at eight feet seven inches from the centre of the great lens. At this place the cone of rays was eight inches in diameter, and the burning focus, now reduced to eight lines in diameter, was one foot from the small lens.

4. In the focus of the small lens, upon a piece of hollow charcoal small pieces of forged iron were placed, which were instantly melted. After fusion, the metal bubbled up, and fumed like nitre in fusion, and then sent off a great number of sparks. This effect (which was observed during the experiments with Tschirnhausen's lens) always took place after the fusion of iron, forged iron, or steel.

5. In order to try the effect upon greater masses, pieces of forged iron, and the end of a nail, were exposed to the focus, and were melted in fifteen seconds. A piece of nail five lines long and one fourth of a line square, which was added to the rest, was instantly fused; and the same was the case with a screw that had a round head, and was eight lines in length.

Burning Glasses.

6. Some days afterwards, a bar of steel, four inches long and four lines square, was exposed, so as to receive the focal image upon the middle of its length. This part was completely melted in five minutes, after having begun to run at the end of the second minute.

7. Platina, in grains, appeared to draw together, to diminish in bulk, and to prepare for fusion. A little after, it bubbled up and smoked. All the grains were united into one mass, without however forming a spherical button like other melted metals. After the platina had undergone this semifusion, it was not attracted by the magnet as it was before the operation.

8. A portion of platina, deprived of the iron which it contained, and therefore not affected by the magnet, lost a part of its bulk, smoked, and formed one mass, which was extended under the hammer.[1]

9. Several experiments were made in order to find the lens that was most proper for collecting the rays after refraction by the large lens. A spirit of wine lens two feet in diameter and four feet focus, a solid lens eighteen inches in diameter and three feet focus, and another thirteen inches in diameter, were successively tried, but none of them produced such a powerful effect as the lens eight inches and a half in diameter, and twenty-two inches and eight lines focus, though it was full of vesicles and striæ.

Messrs Cadet and Brisson made a number of experiments on the refractive power of different fluids, by inclosing them in the lens of M. Trudaine, and observing the variations in its focal length. The object of their experiments was to find a fluid that possessed a greater refractive power than spirits of wine, and was at the same time sufficiently cheap and transparent to be used between the glass segments. Liquid turpentine was the most refractive fluid that they employed; but as they found that its dispersive power was to that of crown-glass as 34 to 28, this fluid was obviously, on this account, unfit for the purpose.[2] The fluid which they preferred was a saturated solution of sal-ammoniac or distilled water.

The most powerful burning-glass that has yet been constructed was made by Mr Parker of Fleet Street. After a great number of experiments, and an expense of above L.700, this able artist succeeded in completing a burning lens of flint-glass three feet in diameter. This powerful instrument is represented in fig. 7. The large lens, which is placed in the ring at A, is doubly convex, and when fixed in its frame, it exposes a surface of two feet eight inches and a half. It is three and a fourth inches thick at the centre, its focal distance is six feet eight inches, the diameter of the burning focus one inch, and the weight of the lens 212 pounds. The rays that were refracted by this lens were received (according to the method of Tschirnhausen) upon a second lens B, whose diameter is sixteen inches out of the frame, and thirteen inches in the frame; its central thickness is an inch and five eighths. The length of its focus is twenty-nine inches, the diameter of the focal image three eighths of an inch, and the weight of the lens twenty-one pounds. The combined focal length of these lenses is five feet three inches, and the diameter of the focus half an inch. These

[1] Messrs Macquer and Beaume are said to have melted small grains of platina by a concave glass twenty-two inches in diameter and twenty-eight inches focus.

[2] Cadet and Brisson, in the course of their experiments, were led to the discovery of achromatic fluid object-glasses, a discovery which has hitherto been referred to a much later date. This discovery is most distinctly contained in the following passage. "Comme la térébinthe cause une dispersion de rayons assez differente de celle que cause le verre, comme nous nous en sommes assurés par l'expérience, ne pourroit on pas faire des objectifs dans lesquels: pour les rendre achromatiques, on feroit usage de cette résine á la place du flint-glass, matière si difficile à se procurer d'une densité uniforme, et sans défauts, surtouts en grands morceaux; mais le développement de cette idée nous meneroit trop loin, et ne fait pas partie de notre sujet actuel!" (*Mem. Acad. Par.* 1777, p. 551.)

Burning Glasses.

lenses are placed at the extremities of a truncated conical frame, consisting of twelve ribs of wood. Near the smaller end B is fixed a rack D, which passes through the pillar L, and is movable by means of a pinion within the pillar, driven by the handle E. A bar of wood F, fixed at G, between the two lower ribs of the cone, carries an apparatus H, which turns on a universal joint at K, and also moves to or from F in a chased mortise. This apparatus, which carries the iron plate I for holding the substances to be examined, may thus be placed exactly in the focus of the lens B. The conical framing is supported by pivots upon a strong iron bow AC, which rests upon a mahogany frame LL, with three feet MMM furnished with castors. Friction wheels are placed under the table N, to facilitate the horizontal motion.

The following experiments with this lens were made in the presence of Major Gardner, and of several members of the Royal Society.

Substances fused, with their weight and time of fusion.	Weight in grains.	Time in seconds.
Common slate	10	2
Scoria of wrought iron	12	2
Gold, pure	20	3
Platina, do.	10	3
Nickel	16	3
Cast iron, a cube	10	3
Silver, pure	20	4
Crystal pebble	7	6
Terra ponderosa, or barytes	10	7
Lava	10	7
Asbestos	10	10
Steel, a cube	10	12
Bar iron, do.	10	12
Garnet	10	17
Copper, pure	33	20
Onyx	10	20
Zeolites	10	23
Pumice stone	10	24
An oriental emerald	2	25
Jasper	10	25
White agate	10	30
Flint, oriental	10	30
A topaz or chrysolite	3	45
Common limestone	10	55
Volcanic clay	10	60
Cornish moor-stone	10	60
White rhomboidal spar	10	60
Rough carnelian	10	75
Rotten stone	10	80

A diamond of ten grains, when exposed to the lens for thirty minutes, was reduced to six grains. It opened, foliated, and emitted whitish fumes, and when again closed it bore a polish and kept its form.

Gold retained its metallic state though exposed for many hours.

The specimens of platina were in different states of approach to a metallic form.

Copper did not lose any of its weight after an exposure of three minutes.

Iron steel shear melted first at the part in contact with the charcoal, while the other part exposed to the focus was unfused.

Iron scoria melted in much less time than the turnings of iron.

Calx of iron from vitriolic acid, precipitated by mild fixed alkali, weighed five grains before exposure, and five and a quarter after it.

The remains of regulus of zinc, after it had melted and was nearly evaporated, were magnetic. It was not pure.

Regulus of cobalt was completely evaporated in 57″.

Regulus of bismuth exposed in charcoal was nearly evaporated. In black lead it began to melt in 2″, and was soon after completely fused. Iron, on exposure of 180″, lost only half a grain; when placed on bone ash it fused in 3″.

Regulus of antimony, thirty-three grains, on charcoal, were fused in 3″, and eleven grains only remained after 195″.

Fine kearsh from the cannon foundery evaporated very fast during 120″, and 30″ afterwards the remainder flowed in globules, which were attracted by the magnet when cold.

Crystal pebble of North America, five grains, contracted in 15″, were perfectly glazed in 135″, ebullesced in 150″, and became of a slate colour and semitransparent.

Agate, oriental flint, cornelian, and jasper, were rendered externally of a glossy form.

Garnet, placed upon black lead, fused in 120″. It became of a darker hue, lost one fourth of a grain, and was attracted by the magnet. Ten cut garnets from a bracelet ran into one another in a few seconds.

Mr Wedgewood's pyrometrical clay ran into a white enamel in a few seconds. Other seven kinds of clay sent by that gentleman were vitrified.

Limestone was sometimes vitrified and sometimes agglutinated. A globule from one of the specimens flew into a thousand pieces when put into the mouth.

Stalactites zeolithus spatosus, nine grains, took a globular form in 60″. The globule began to become clear in 148″. It became perfectly transparent in 155″. When cold, its transparency diminished, and it assumed a beautiful red colour.

Lavas and other volcanic products likewise yielded to the power of this lens.

In the year 1802 Sir Joseph Banks, Dr Crawford, and some other members of the Royal Society, were present at an experiment for concentrating the lunar rays; but though the most sensible thermometers were applied, it was rather thought that there was a diminution than an increase of heat.

It was not to be expected that this powerful lens, which cost so large a sum of money, could have been retained in the hands of Mr Parker. That ingenious artist was naturally desirous to indemnify himself for the expense of its construction. A subscription was therefore opened for purchasing the lens as a national instrument; but this subscription failing, Mr Parker was induced to sell it to Captain Mackintosh, who accompanied Lord Macartney to China. This valuable instrument was left at Pekin, where it still remains.

This glass of Parker's is perhaps the largest solid lens that can be made in practice, without very great difficulties and expense in procuring so large a quantity of material of sufficient purity, and casting it in the lenticular form free of faults; and supposing these overcome, we have still the great thickness in the centre, and the enormous absorption of light in consequence of it, while the exterior portion of the glass by the spherical aberration disperses the rays from the focal point. With the compound lenses of Buffon, again, there is no limit to the magnitude further than what arises from the reflection of light near the circumference of the glass when the rays fall there very obliquely. If the diameter of the lens were to be equal to the chord of 48° of the sphere to which the lens has been formed, the whole of the incident light near the circumference would be reflected.

Burning sphere of Sir David Brewster.

To augment still further the power of burning instruments, Sir David Brewster proposes a compound instrument, which he terms a burning sphere, consisting of lenses and reflectors combined together,—a series of lenses be-

ing arranged in a circle having their foci all in the centre, and having each a plane reflector so situated as to throw the sun's rays in the direction of the axis of the lens. The following is his description of it as represented in fig. 8, which is merely a section of the sphere, and represents only five of the lenses and four of the mirrors. The lenses A, B, C, D, E, which may be of any diameter and focal length, are so placed in the spherical surface AMN, that their principal foci exactly coincide in the point F. If any of the lenses have a different focal length from the rest, the coincidence of its focus with that of the other may be easily effected by varying its distance from F. The whole spherical surface, whose section is AMN, except a small opening for admitting the object to be fused, may be covered with lenses, having all their foci coincident at F; though it will, perhaps, be more convenient to have the posterior part MN without lenses, and occupied by a mirror of nearly the same radius FA as the sphere. The object of this mirror is to throw back upon the object at F the light that passes by it, without producing any effect. Each of the lenses, except the lens A, is furnished with a plane glass mirror, which may be either fixed to the general frame of the sphere, or placed upon a separate stand. When this combination is completed the sphere is exposed to the sun, so that its rays may fall at right angles upon the lens A, which will of course concentrate them at F, and produce a pretty intense heat. The plane mirror PQ, when properly adjusted, will reflect the sun's light perpendicularly upon the lens B, by which it will be refracted accurately to the focus F, and produce a degree of heat fully one half of what was produced by the direct refracted rays of the sun through the lens A. A similar effect will be produced by the mirror RS and lens D, the mirror TU and lens C, the mirror VW and lens E, and by all the other mirrors and lenses which are not seen in the section. The effect may be still further increased by the addition of a large lens at XX. As the angle which the surface of each mirror forms with the axis of its corresponding lens is a constant quantity, the mirrors may be all fixed to the general frame of the sphere, and therefore the only adjustment which the instrument will require is to keep the axis of the lens A parallel to the direction of the solar rays.

In order to estimate the advantages of this construction, let us compare its effects with those of a solid lens, which exposes the same area of glass to the incident rays.

1. In the burning sphere, almost the only diminution of light is that which arises from reflection by the plane mirrors, and which may be estimated pretty accurately at one half of the incident light; but this loss can be amply compensated by adding a few more lenses.

2. In the solid lens a great diminution of light arises from the thickness of the central portions, and from the obliquity of the parts at the circumference, which, we conceive, will be fully equal to the light lost by reflection in the burning sphere.

3. In the burning sphere the lenses may be obtained of much purer glass than can be got for a solid lens; and therefore, *cæteris paribus*, they will transmit more light.

4. Owing to the small size of each lens in the burning sphere, the diminution of effect arising both from spherical aberration and from the aberration of colour will be very much less than in the solid lens.

5. In the burning sphere the effect is greatly increased, in consequence of the shortness of the focal length of each lens, and the greater concentration of the incident light.

6. In the burning sphere all kinds of lenses may be combined. They may be made of any kind of glass, of any diameter, and of any focal length; and the lenses belonging to different individuals may be combined for any occasional experiment in which a great intensity of heat is requisite.

BURNISHER, one who burnishes. The instrument called a burnisher is of different kinds; as a piece of round polished steel, a dog's or wolf's tooth, a piece of agate, &c. The burnishers of engravers on copper usually serve with one end to burnish, and with the other to scrape.

BURNLEY, a market-town of England, 22 miles north of Manchester, in the county of Lancaster, hundred of Blackburn, and parish of Whalley. It is pleasantly situated in a narrow valley on the Burn, from which it derives its name. Besides the chapel, an ancient structure of various styles of architecture, there are places of worship for Methodists, Independents, Roman Catholics, &c. There is a free grammar-school, national, British, and other schools, mechanics' institute, savings-bank, and several charities. The chief manufactures are cotton and woollen goods, with iron and brass foundries, breweries, tanneries, and roperies. In the vicinity are coal mines, and limestone and slate quarries. Market-days Monday and Saturday. The Leeds and Liverpool canal nearly surrounds the town, which is connected by railway with Manchester, &c. Pop. (1851) 20,828.

BURNS, Robert, the national bard of Scotland, was born on the 25th of January 1759, in a clay-built cottage about two miles south of the town of Ayr. He was the eldest son of William Burnes, or Burness, who at the period of Robert's birth was gardener and overseer to a gentleman of small estate; but resided on a few acres of land which he had on lease from another person. The father was a man of strict religious principles, and also distinguished for that penetration and knowledge of mankind which was afterwards so conspicuous in his son. The mother of the poet was likewise a very sagacious woman, and possessed an inexhaustible store of ballads and legendary tales, with which she nourished the infant imagination of him whose own productions were destined to excel them all.

These worthy individuals laboured diligently for the support of an increasing family; nor, in the midst of harassing struggles, did they neglect the mental improvement of their offspring; a characteristic of Scottish parents, even under the most depressing circumstances. In his sixth year Robert was put under the tuition of one Campbell, and subsequently under Mr John Murdoch, a

Burns.

very faithful and pains-taking teacher. With this individual he remained for a few years, and was accurately instructed in the first principles of composition. The poet and his brother Gilbert were the aptest pupils in the school, and were generally at the head of the class. Mr Murdoch, in afterwards recording the impressions which the two brothers made on him, says, "Gilbert always appeared to me to possess a more lively imagination, and to be more of the wit, than Robert. I attempted to teach them a little church-music. Here they were left far behind by all the rest of the school. Robert's ear in particular was remarkably dull, and his voice untunable. It was long before I could get them to distinguish one tune from another. Robert's countenance was generally grave, and expressive of a serious, contemplative, and thoughtful mind. Gilbert's face said, *Mirth, with thee I mean to live;* and certainly, if any person who knew the two boys had been asked which of them was the most likely to court the muses, he would never have guessed that *Robert* had a propensity of that kind."

Besides the tuition of Mr Murdoch, Burns received instructions from his father in writing and arithmetic. Under their joint care he made rapid progress, and was remarkable for the ease with which he committed devotional poetry to memory. The following extract from his letter to Dr Moore in 1787 is interesting, from the light which it throws upon his progress as a scholar, and on the formation of his character as a poet:—"At those years," says he, "I was by no means a favourite with any body. I was a good deal noted for a retentive memory, a stubborn sturdy something in my disposition, and an enthusiastic idiot piety. I say *idiot* piety, because I was then but a child. Though it cost the schoolmaster some thrashings, I made an excellent scholar; and by the time I was ten or eleven years of age, I was a critic in substantives, verbs, and particles. In my infant and boyish days, too, I owed much to an old woman who resided in the family, remarkable for her ignorance, credulity, and superstition. She had, I suppose, the largest collection in the country, of tales and songs concerning devils, ghosts, fairies, brownies, witches, warlocks, spunkies, kelpies, elf-candles, dead-lights, wraiths, apparitions, cantrips, giants, enchanted towers, dragons, and other trumpery. This cultivated the latent seeds of poetry; but had so strong an effect on my imagination, that to this hour, in my nocturnal rambles, I sometimes keep a sharp look-out in suspicious places; and though nobody can be more sceptical than I am in such matters, yet it often takes an effort of philosophy to shake off these idle terrors. The earliest composition that I recollect taking pleasure in was *The Vision of Mirza*, and a hymn of Addison's, beginning, *How are thy servants blest, O Lord!* I particularly remember one half-stanza, which was music to my boyish ear—

For though on dreadful whirls we hung
High on the broken wave.—

I met with these pieces in *Mason's English Collection*, one of my school-books. The first two books I ever read in private, and which gave me more pleasure than any two books I ever read since, were, *The Life of Hannibal*, and *The History of Sir William Wallace*. Hannibal gave my young ideas such a turn, that I used to strut in raptures up and down after the recruiting drum and bagpipe, and wish myself tall enough to be a soldier; while the story of Wallace poured a tide of Scottish prejudice into my veins, which will boil along there till the flood-gates of life shut in eternal rest."

Mr Murdoch's removal from Mount Oliphant deprived Burns of his instructions; but they were still continued by the father of the bard. About the age of fourteen he was sent to school every alternate week for the improvement of his writing. In the meanwhile he was busily employed upon the operations of the farm; and, at the age of fifteen, was considered as the principal labourer upon it. About a year after this he gained three weeks of respite, which he spent with his old tutor Murdoch at Ayr, in revising the English grammar, and in studying the French language, in which he made uncommon progress. Ere his sixteenth year elapsed, he had considerably extended his reading. The vicinity of Mount Oliphant to Ayr afforded him facilities for gratifying what had now become a passion. Among the books which he had perused were some plays of Shakspeare, Pope, the works of Allan Ramsay, and a collection of songs which constituted his *vade-mecum*. "I pored over them," says he, "driving my cart or walking to labour, song by song, verse by verse, carefully noticing the true tender or sublime from affectation and fustian." So early did he evince his attachment to the lyric muse, in which he was destined to surpass all who have gone before or succeeded him.

At this period the family removed to Lochlea, in the parish of Tarbolton. Some time before, however, he had made his first attempt in poetry. It was a song addressed to a rural beauty about his own age; and though possessing no great merit as a whole, it contains some lines and ideas which would have done honour to him at any age. After the removal to Lochlea his literary zeal slackened, for he was thus cut off from those acquaintances whose conversation stimulated his powers, and whose kindness supplied him with books. For about three years after this period he was busily employed upon the farm; but at intervals he paid his addresses to the poetic muse, and with no common success. The summer of his nineteenth year was spent in the study of mensuration, surveying, &c. at a small sea-port town, a good distance from home. He returned to his father's considerably improved. "My reading," says he, "was enlarged with the very important addition of Thomson's and Shenstone's works. I had seen human nature in a new phasis; and I engaged several of my school-fellows to keep up a literary correspondence with me. This improved me in composition. I had met with a collection of letters by the wits of Queen Anne's reign, and I pored over them most devoutly; I kept copies of any of my own letters that pleased me; and a comparison between them and the composition of most of my correspondents flattered my vanity. I carried this whim so far, that though I had not three farthings worth of business in the world, yet almost every post brought me as many letters as if I had been a broad plodding son of day-book and ledger."

His mind, peculiarly susceptible of tender impressions, was continually the slave of some rustic charmer. In the "heat and whirlwind of his love," he generally found relief in poetry, by which, as by a safety valve, his turbulent passions were allowed to have vent. He formed the resolution of entering the matrimonial state; but his circumscribed means of subsistence as a farmer preventing his taking that step, he resolved on becoming a flax-dresser, for which purpose he removed to the town of Irvine in 1781. The speculation turned out unsuccessful; for the shop catching fire, was burnt, and the poet returned to his father without a sixpence. During his stay at Irvine he had met with Ferguson's poems. This circumstance was of some importance to Burns, for it roused his poetic powers from the torpor into which they had fallen, and in a great measure finally determined the *Scottish* character of his poetry. He here also contracted some friendships, which he himself says did him mischief; and, by his brother Gilbert's account, from this date there was a serious change in his conduct. The venerable and ex-

cellent parent of the poet died soon after his son's return. The support of the family now devolving upon Burns, in conjunction with his brother he took a sub-lease of the farm of Mossgiel, in the parish of Mauchline. The four years which he resided upon this farm were the most important of his life. It was here he felt that nature had designed him for a poet; and here, accordingly, his genius began to develope its energies in those strains which will make his name familiar to all future times, the admiration of every civilized country, and the glory and boast of his own.

The vigour of Burns's understanding, and the keenness of his wit, as displayed more particularly at masonic meetings and debating clubs, of which he formed one at Mauchline, began to spread his fame as a man of uncommon endowments. He now could number as his acquaintance several clergymen, and also some gentlemen of substance; amongst whom was Mr Gavin Hamilton, writer in Mauchline, one of his earliest patrons. One circumstance more than any other contributed to increase his notoriety. "Polemical divinity," says he to Dr Moore in 1787, "about this time was putting the country half mad; and I, ambitious of shining in conversation-parties on Sundays, at funerals, &c. used to puzzle Calvinism with so much heat and indiscretion, that I raised a hue-and-cry of heresy against me, which has not ceased to this hour." The farm which he possessed belonged to the Earl of Loudon, but the brothers held it in sub-lease from Mr Hamilton. This gentleman was at open feud with one of the ministers of Mauchline, who was a rigid Calvinist. Mr Hamilton maintained opposite tenets; and it is not matter of surprise that the young farmer should have espoused his cause, and brought all the resources of his genius to bear upon it. The result was *The Holy Fair*, *The Ordination*, *Holy Willie's Prayer*, and other satires, as much distinguished for their coarse severity and bitterness, as for their genius.

The applause which greeted these pieces emboldened the poet, and encouraged him to proceed. In his life by his brother Gilbert, a very interesting account is given of the occasions which gave rise to the poems, and the chronological order in which they were produced. The exquisite pathos and humour, the strong manly sense, the masterly command of felicitous language, the graphic power of delineating scenery, manners, and incidents, which appear so conspicuously in his various poems, could not fail to call forth the admiration of those who were favoured with a perusal of them. But the clouds of misfortune were gathering darkly above the head of him who was thus giving delight to a large and widening circle of friends. The farm of Mossgiel proved a losing concern; and an amour with Miss Jane Armour, afterwards Mrs Burns, had assumed so serious an aspect, that he at first resolved to fly from the scene of his disgrace and misery. One trait of his character, however, must be mentioned. Before taking any steps for his departure, he met Miss Armour by appointment, and gave into her hands a written acknowledgment of marriage, which, when produced by a person in her situation, is, according to the Scots law, to be accepted as legal evidence of an *irregular* marriage having really taken place. This the lady burned at the persuasion of her father, who was adverse to a marriage; and Burns, thus wounded in the two most powerful feelings of his mind, his love and pride, was driven almost to insanity. Jamaica was his destination; but as he did not possess the money necessary to defray the expense of his passage out, he resolved to publish some of his best poems, in order to raise the requisite sum. These views were warmly promoted by some of his more opulent friends; and a sufficiency of subscribers having been procured, one of the finest volumes of poetry that ever appeared in the world issued from the provincial press of Kilmarnock.

It is hardly possible to imagine with what eager admiration and delight they were everywhere received. They possessed in an eminent degree all those qualities which invariably contribute to render any literary work quickly and permanently popular. They were written in a phraseology of which all the powers were universally felt, and which being at once antique, familiar, and now rarely written, was therefore fitted to serve all the dignified and picturesque uses of poetry, without making it unintelligible. The imagery and the sentiments were at once natural, impressive, and interesting. Those topics of satire and scandal in which the rustic delights; that humorous imitation of character, and that witty association of ideas familiar and striking, yet not naturally allied to one another, which has force to shake his sides with laughter; those fancies of superstition, at which one still wonders and trembles; those affecting sentiments and images of true religion, which are at once dear and awful to the heart; were all represented by Burns with the magical power of true poetry. Old and young, high and low, grave and gay, learned and ignorant, all were alike surprised and transported.

In the mean time, a few copies of these fascinating poems found their way to Edinburgh, and having been read to Dr Blacklock, obtained his warmest approbation; and he advised the author to repair to Edinburgh. Burns lost no time in complying with this request; and accordingly, towards the end of the year 1786, he set out for the capital, where he was received by Dr Blacklock with the most flattering kindness, and introduced to every person of taste among that excellent man's friends. Multitudes now vied with each other in patronising the rustic poet. Those who possessed at once true taste and ardent philanthropy were soon united in his praise; those who were disposed to favour any good thing belonging to Scotland, purely because it was Scottish, gladly joined the cry; while those who had hearts and understandings to be charmed without knowing why, when they saw their native customs, manners, and language, made the subjects and the materials of poesy, could not suppress that impulse of feeling which struggled to declare itself in favour of Burns.

Thus did Burns, ere he had been many weeks in Edinburgh, find himself the object of universal curiosity, favour, admiration, and fondness. He was sought after, courted with attentions the most respectful and assiduous, feasted, flattered, caressed, and treated by all ranks as the great boast of his country, whom it was scarcely possible to honour and reward in a degree equal to his merits.

A new edition of his poems was called for; and the public mind was directed to the subject by Henry Mackenzie, who dedicated a paper in the *Lounger* to a commendatory notice of the poet. This circumstance will ever be remembered to the honour of that polished writer, not only for the warmth of the eulogy he bestowed, but because it was the first printed acknowledgment which had been made to the genius of Burns. The copyright was sold to Creech for L.100; but the friends of the poet advised him to forward a subscription. The patronage of the Caledonian Hunt, a very influential body, was obtained. The list of subscribers rapidly rose to 1500; many gentlemen paying a great deal more than the price of the volume; and it was supposed that the poet derived from the subscription and the sale of his copy-right a clear profit of at least L.700.

The conversation of Burns, according to the testimony of all the eminent men who heard him, was even more wonderful than his poetry. He affected no soft air nor graceful motions of politeness, which might have ill accorded

with the rustic plainness of his native manners. Conscious superiority of mind taught him to associate with the great, the learned, and the gay, without being overawed into any such bashfulness as might have rendered him confused in thought or hesitating in elocution. He possessed withal an extraordinary share of plain common sense or mother-wit, which prevented him from obtruding upon persons, of whatever rank, with whom he was admitted to converse, any of those effusions of vanity, envy, or self-conceit, in which authors who have lived remote from the general practice of life, and whose minds have been almost exclusively confined to contemplate their own studies and their own works, are but too prone to indulge. In conversation he displayed a sort of intuitive quickness and rectitude of judgment upon every subject that arose. The sensibility of his heart, and the vivacity of his fancy, gave a rich colouring to whatever opinions he was disposed to advance; and his language was thus not less happy in conversation than in his writings. Hence those who had met and conversed with him once, were pleased to meet and to converse with him again and again.

For some time he associated only with the virtuous, the learned, and the wise, and the purity of his morals remained uncontaminated. But unfortunately he fell, as others have fallen in similar circumstances. He suffered himself to be surrounded by persons who were proud to tell that they had been in company with Burns, and had seen Burns as loose and as foolish as themselves. He now also began to contract something of arrogance in conversation. Accustomed to be among his associates what is vulgarly but expressively called "the cock of the company," he could scarcely refrain from indulging in a similar freedom and dictatorial decision of talk, even in the presence of persons who could less patiently endure presumption.

After remaining some months in the Scottish metropolis, basking in the noontide sun of a popularity which, as Dugald Stewart well remarks, would have turned any head but his own, he formed a resolution of returning to the shades whence he had emerged, but not before he had perambulated the southern border. On the 6th of May 1787 he set out on his journey, and, visiting all that appeared interesting on the north of the Tweed, proceeded to Newcastle and other places on the English side. He returned in about two months to his family at Mauchline; but in a short period he again set out on an excursion to the north, where he was most flatteringly received by all the great families. On his return to Mossgiel he completed his marriage with Miss Armour. He then concluded a bargain with Mr Miller of Dalswinton, for a lease of the farm of Elliesland, on advantageous terms.

Burns entered on possession of this farm at Whitsunday 1788. He had formerly applied with success for an excise commission, and during six weeks of the summer of this year he had to attend to the business of that profession at Ayr. His life for some time was thus wandering and unsettled; and Dr Currie mentions this as one of his chief misfortunes. Mrs Burns came home to him towards the end of the year, and the poet was accustomed to say that the happiest period of his life was the first winter he spent in Elliesland. The neighbouring farmers and gentlemen, pleased to obtain for a neighbour the poet by whose works they had been delighted, kindly sought his company, and invited him to their houses. Burns, however, found an inexpressible charm in sitting down beside his wife, at his own fireside; in wandering over his own grounds; in once more putting his hand to the spade and the plough; in forming his inclosures, and managing his cattle. For some months he felt almost all that felicity which fancy had taught him to expect in his new situation. He had been for a time idle; but his muscles were not yet unbraced for rural toil. He now seemed to find a joy in being the husband of the mistress of his affections, and in seeing himself the father of children such as promised to attach him for ever to that modest, humble, and domestic life, in which alone he could hope to be permanently happy. Even his engagements in the service of the excise did not, at first, threaten either to contaminate the poet or to ruin the farmer.

From various causes, the farming speculation did not succeed. Indeed, from the time he obtained a situation under government, he gradually began to sink the farmer in the exciseman. Occasionally he assisted in the rustic occupations of Elliesland, but for the most part he was engaged in very different pursuits. In his professional perambulations over the moors of Dumfriesshire he had to encounter temptations which a mind and temperament like his found it difficult to resist. His immortal works had made him universally known and enthusiastically admired; and accordingly he was a welcome guest at every house, from the most princely mansion to the lowest country inn. In the latter he was too frequently to be found as the presiding genius, and master of the orgies. However, he still continued at intervals to cultivate the muse; and, besides a variety of other pieces, he produced at this period the inimitable poem of Tam o'Shanter. Johnson's Miscellany was also indebted to him for the finest of its lyrics. One pleasing trait of his character must not be overlooked. He superintended the formation of a subscription library in the parish, and took the whole management of it upon himself. These institutions, though common now, were not so at the period of which we write; and it should never be forgotten that Burns was amongst the first, if not the very first, of their founders in the rural districts of southern Scotland.

Towards the close of 1791 he finally abandoned his farm; and obtaining an appointment to the Dumfries division of excise, he repaired to that town on a salary of L.70 per annum. All his principal biographers concur in stating that after settling in Dumfries his moral career was downwards. Heron, who had some acquaintance with the matter, says, "His dissipation became still more deeply habitual; he was here more exposed than in the country to be solicited to share the revels of the dissolute and the idle; foolish young men flocked eagerly about him, and from time to time pressed him to drink with them, that they might enjoy his wit. The Caledonian Club, too, and the Dumfriesshire and Galloway Hunt, had occasional meetings in Dumfries after Burns went to reside there; and the poet was of course invited to share their conviviality, and hesitated not to accept the invitation. In the intervals between his different fits of intemperance he suffered the keenest anguish of remorse, and horribly afflictive foresight. His Jane behaved with a degree of conjugal and maternal tenderness and prudence, which made him feel more bitterly the evil of his misconduct, although they could not reclaim him."

This is a dark picture, perhaps too dark. The Rev. Mr Gray, who, as the teacher of his son, was intimately acquainted with Burns, and had frequent opportunities of judging of his general character and deportment, gives a more amiable portrait of the bard. Being an eye-witness, the testimony of this gentleman must be allowed to have some weight. "The truth is," says he, "Burns was seldom *intoxicated*. The drunkard soon becomes besotted, and is shunned even by the convivial. Had he been so, he could not have long continued the idol of every party." This is strong reasoning; and he goes on to mention other circumstances which seem to confirm the truth of his position. In balancing these two statements, a juster estimate of the moral deportment of Burns may be formed.

In the year 1792 party politics ran to a great height in Scotland, and the liberal and independent spirit of Burns did certainly betray him into some indiscretions. A general opinion prevails, that he so far lost the good graces of his superiors by his conduct, as to consider all prospects of future promotion as hopeless. But this appears not to have been the case; and the fact that he acted as supervisor before his death is a strong proof to the contrary. Of his political verses few have as yet been published. But in these he warmly espoused the cause of the Whigs, which kept up the spleen of the other party, already sufficiently provoked; and this may in some measure account for the bitterness with which his own character was attacked.

Whatever opinion may be formed of the extent of his dissipation in Dumfries, one fact is unquestionable, that his powers remained unimpaired to the last; it was there he produced his finest lyrics, and they are the finest, as well as the purest, that ever delighted mankind. Besides Johnson's *Museum*, in which he took an interest to the last, and contributed most extensively, he formed a connection with Mr George Thomson of Edinburgh. This gentleman had conceived the laudable design of collecting the national melodies of Scotland, with accompaniments by the most eminent composers, and poetry by the most eminent writers, in addition to those words which were originally attached to them. From the multitude of songs which Burns wrote from the year 1792 till the commencement of his illness, it is evident that few days could have passed without his producing some stanzas for the work. The following passage from his correspondence, which was also most extensive, proves that his songs were not hurriedly got up, but composed with the utmost care and attention. "Until I am complete master of a tune in my own singing, such as it is," says he, "I can never compose for it. My way is this. I consider the poetic sentiment correspondent to my idea of the musical expression,—then choose my theme,—compose one stanza. When that is composed, which is generally the most difficult part of the business, I walk out,—sit down now and then,—look out for objects in nature round me that are in unison or harmony with the cogitations of my fancy, and workings of my bosom,—humming every now and then the air, with the verses I have framed. When I feel my muse beginning to jade, I retire to the solitary fireside of my study, and there commit my effusions to paper; swinging at intervals on the hind legs of my elbow-chair, by way of calling forth my own critical strictures, as my pen goes. Seriously, this, at home, is almost invariably my way." This is not only interesting for the light which it throws upon his method of composition, but it proves that conviviality had not as yet greater charms for him than the muse.

From his youth Burns had exhibited ominous symptoms of a radical disorder in his constitution. A palpitation of the heart, and a derangement of the digestive organs, were conspicuous. These were, doubtless, increased by his indulgences, which became more frequent as he drew towards the close of his career. In the autumn of 1795 he lost an only daughter, which was a severe blow to him. Soon afterwards he was seized with a rheumatic fever; and "long the die spun doubtful," says he, in a letter to his faithful friend Mrs Dunlop, "until, after many weeks of a sick bed, it seems to have turned up life, and I am beginning to crawl across my room." The cloud behind which his sun was destined to be eclipsed at noon had begun to darken above him. Before he had completely recovered, he had the imprudence to join a festive circle; and, on his return from it, he caught a cold, which brought back his trouble upon him with redoubled severity. Sea-bathing was had recourse to, but with no ultimate success. He lingered until the 21st of July 1796, when he expired. The interest which the death of Burns excited was intense. All differences were forgotten; his genius only was thought of. On the 26th of the same month he was conveyed to the grave, followed by about ten thousand individuals of all ranks, many of whom had come from distant parts of the country to witness the solemnity. He was interred with military honours by the Dumfries volunteers, to which body he had belonged.

Thus, at the age of thirty-seven, an age when the mental powers of man have scarcely reached their climax, died Robert Burns, one of the greatest poets whom his country has produced. It is unnecessary to enter into any lengthened analysis of his poetry or character. His works are universally known and admired, and criticism has been drawn to the dregs upon the subject; and that, too, by the greatest masters who have appeared since his death,—no mean test of the great merits of his writings. He excels equally in touching the heart by the exquisiteness of his pathos, and exciting the risible faculties by the breadth of his humour. His lyre had many strings, and he had equal command over them all; striking each, and frequently in chords, with the skill and power of a master. That his satire sometimes degenerates into coarse invective, cannot be denied; but where personality is not permitted to interfere, his poems of this description may take their place beside any thing of the kind which has ever been produced, without being disgraced by the comparison. It is unnecessary to re-echo the praises of his best pieces, as there is no epithet of admiration which has not been bestowed upon them. Those who had best opportunities of judging, are of opinion that his works, stamped as they are with the impress of sovereign genius, fall short of the powers he possessed. It is therefore to be lamented that he undertook no great work of fiction or invention. Had circumstances permitted, he would probably have done so; but his excise duties, and without doubt his own follies, prevented him. His passions were strong, and his capacity of enjoyment corresponded with them. These continually precipitated him into the vortex of pleasure, where alone they could be gratified; and the re-action consequent upon such indulgences (for he possessed the finest discrimination between right and wrong) threw him into low spirits, to which he was also constitutionally liable. His mind, being thus never for any length of time in an equable tone, could scarcely pursue with steady regularity a work of any length. His moral aberrations, as detailed by some of his biographers, have been exaggerated, as already noticed. This has been proved by the testimony of many witnesses, from whose authority there can be no appeal; for they had the best opportunities of judging. In fine, it may be doubted whether he has not, by his writings, exercised a greater power over the minds of men, and the general system of life, than has been exercised by any other modern poet. A complete edition of his works, in four vols. 8vo, with a life, was published by Dr Currie of Liverpool, for the benefit of his family, to whom it realized a handsome sum. Editions have been since multiplied beyond number; and several excellent biographies of the poet have been published, particularly that by Mr Lockhart. (J. F. S.)

BURNTISLAND, a small seaport town, and a royal and parliamentary burgh in the district of Kirkcaldy, in the county of Fife, on the opposite shore of the Frith of Forth from Leith, from which it is about six miles distant, in Lat. 56. 4. N. Long. 3. 13. W. The town is pleasantly situated on the sea-coast, and is clean and well built. The beach is sandy and admirably adapted for bathing, and the town is on this account much frequented by the people of Edinburgh and other parts of Scotland during the summer months. A large proportion of the inhabitants are engaged

in the herring and whale fisheries; and there is a considerable though decreasing trade in ship-building. The quantity of spirits manufactured at the distilleries is very large. The general aspect of the town has greatly improved since the completion of the Edinburgh and Northern railway, which connects Burntisland with Edinburgh on the one side, and the more important towns of the north of Scotland on the other. Steamers pass and repass between Burntisland and the opposite shore every hour. There are no public buildings of any importance in the town except the town-hall, the church, a dissenting chapel, and the school-house. The town is governed by a municipal council, consisting of a provost and twenty-one councillors, and its revenue amounts to L.1022. It is in the presbytery of Kirkcaldy; and the living, which is worth L.180 per annum, is in the patronage of the crown. There is a lighthouse at the end of the pier, erected in 1845, which is seen at the distance of eight miles. Pop. (1851) 2329.

BURROW, Sir James, master of the Crown-office, was born in 1701. He was elected a fellow of the Royal Society and of the Society of Arts in 1751: and on the death of Mr West in 1772, he filled the president's chair at the Royal Society till the anniversary election, when he resigned it to Sir John Pringle. In 1773, when the society presented an address to His Majesty, he received the honour of knighthood. He published two volumes of valuable law reports in 1766; two others in 1771 and 1776; and a volume of decisions of the court of king's bench upon settlement cases from 1732 to 1772, to which was subjoined an Essay of Punctuation, in three parts, 4to, 1768, 1772, 1776. The Essay was also printed separately in 4to, 1773. He published, without his name, A few Anecdotes and Observations relating to Oliver Cromwell and his family, serving to rectify several errors concerning him, published by Nicol. Comm. Papadopoli, in his *Historia Gymnasii Patavini*, 1763, 4to. Sir James died in 1782.

BURSAR, or Burser (*Bursarius*, from *bursa* a purse), is used by the middle-age writers for the treasurer or cash-keeper of a college or monastery.

Bursar also denotes one who receives a small sum out of a burse or fund appropriated for that purpose; as the exhibitioners in the Scottish universities.

BURSE (French *bourse*), a public edifice in certain continental cities, for the meeting of merchants to negotiate bills, and to confer on matters of trade and money. In England and in America, such building is called an *exchange*. The first place of this kind to which the name *burse* was given was at Bruges. From this city the name was afterwards transferred to the like places in others, as in Antwerp, Amsterdam, Bergen in Norway, and London. This last, anciently known by the name of the *common burse of merchants*, had the denomination of the *royal exchange* given it by Queen Elizabeth. In the time of the Romans there were public places for the meeting of merchants in most of the trading cities in the empire. That built at Rome B.C. 495, in the consulate of Appius Claudius and Publius Servilius, was denominated the *college of merchants*. Some remains of it are still to be seen, and are known by the modern Romans under the name *loggia*. The Hans towns, after the example of the Romans, gave to their burses the name of *colleges*.

BURSLEM, a market-town of Staffordshire, in the hundred of Pirehill and parish of Burslem, 17 miles south of Manchester, and 150 miles from London. It stands on a gentle eminence near the Trent and Mersey canal, and is the principal town in the "Potteries' district." It has numerous neat and commodious dwellings for the working-classes, large manufactories, and some handsome villas. The chief public buildings are the chapel with an ancient tower, the market-house, the town-hall, newsroom, mechanics' institute, &c. Pop. (1851) 15,954, principally engaged in the potteries. Josiah Wedgewood, whose name is so intimately associated with earthenware manufactures, was born here in 1730.

BURTON, John, D.D., a learned divine, born in 1696, at Wembworth in Devonshire, of which parish his father was rector. He was educated at Corpus Christi College, Oxford. In 1725, being then pro-proctor and master of the schools, he spoke before the determining bachelor a Latin oration, entitled "*Heli*, or an Instance of a Magistrate's erring through unseasonable Lenity;" and he afterwards treated the same subject still more fully in four Latin sermons before the university, and published them with appendices. He also introduced into the schools Locke and other eminent modern philosophers, as suitable companions to Aristotle, and printed a double series of philosophical questions for the use of the younger students. When the settling of Georgia was in agitation, Dr Bray, Dr Stephen Hales, Dr Berriman, and other learned divines, entreated Mr Burton's pious assistance in that undertaking. This he readily gave, by preaching before the society in 1732, and publishing his sermon, with an appendix on the state of that colony. About the same time, on the death of Dr Edward Littleton, whose widow he subsequently married, he was presented by Eton College to the vicarage of Maple-Derham, in Oxfordshire. In 1760 he exchanged his vicarage of Maple-Derham for the rectory of Worplesdon in Surrey. He collected and published, in one volume, all his scattered pieces, under the title of *Opuscula Miscellanea;* and soon after died, on the 11th of February 1771.

Burton, *Robert*, known to the learned by the name of *Democritus junior*, was a younger brother of the William Burton who wrote the "Antiquities of Leicestershire." He was born of an ancient family at Lindley, in that county, on the 8th of February 1576. He received the rudiments of his education at the free school of Sutton Colefield, in Warwickshire; in the year 1593 he was sent to Brasennose College, Oxford, and in 1599 was elected student of Christ Church. In 1616 he was presented by the dean and canons of Christ Church to the vicarage of St Thomas, in the west suburb of Oxford, to the parishioners of which it is said that he always gave the sacrament in wafers; and this, with the rectory of Segrave in Leicestershire, given him some time afterwards by George Lord Berkeley, he held to the day of his death, which happened in January 1639. He was a man of great general learning, a distinguished philosopher, an exact mathematician, and, what constitutes the peculiarity of his character, a very curious calculator of nativities. Though he was extremely studious, and of a melancholy disposition, he was an agreeable companion, and possessed a large fund of humour. The *Anatomy of Melancholy*, by *Democritus junior*, as he calls himself, shows that these different qualities were strangely mixed together in his composition. This book was printed first in quarto, afterwards in folio, in 1624, 1632, 1638, and 1652, to the great emolument of the bookseller, who, as Wood tells us, got an estate by it. Some circumstances attending his death occasioned strange suspicions. He died in his chamber at or very near the time which, it seems, he had some years before predicted from the calculation of his nativity; and this exactness made it whispered about, that for the glory of astrology and rather than that his calculation should fail, he became a *felo de se*. This, however, was generally discredited. He was buried with due solemnity in the cathedral of Christ Church, and had a handsome monument erected to his memory. He left behind him a very choice collection of books, many of which he bequeathed to the Bodleian Library, along with L.100 to Christ Church, the interest of which was to be laid out yearly in books for the library of that college.

BURTON-UPON-TRENT, a market-town in the parish of the same name, hundred of North Offlow, and

county of Stafford, is situated on the Trent, 11 miles S.W. of Derby. Pop. (1851) 7934. An abbey was founded here by one of the earls of Mercia as early as 1004, of which some remains are still to be seen. The river is here crossed by an ancient bridge erected before the Conquest, measuring 1545 feet in length, and having 37 arches. There are two churches and numerous dissenting places of worship, a grammar-school, town-hall, assembly-rooms, savings-bank, subscription library, and several charities. Market-day Thursday. The river is navigable for barges up to the town. It was formerly noted for its alabaster works, but is now chiefly celebrated for the ale to which it gives name. The Grand Trunk canal uniting the Mersey with the Trent passes the town.

BURTSCHEID, or BORCETTE, a town of Prussia, in the province of the Rhine and government of Aix-la-Chapelle, immediately S.E. of the town of that name. It has considerable manufactures of woollen-cloth cassimeres, Prussian blue, &c., and several hot sulphurous springs. Pop. (1849) 5657.

BURY, a parliamentary borough, and manufacturing town of England, in the county of Lancaster, on the Irwell, 8 miles N.N.W. of Manchester. The general appearance of the town has latterly been much improved by the widening of the streets and the erection of many handsome edifices. The parliamentary borough, comprising the townships of Bury and Elton, in 1851, had 31,262 inhabitants. Registered electors (1851–52) 959. It has returned one member to parliament since the passing of the Reform bill; and is governed by 3 constables appointed by the Earl of Derby, lord of the manor. It has 3 churches, 6 chapels, and numerous dissenting places of worship, Kay's free grammar-school, with two exhibitions of L.25 each at either university, a newsroom, mechanics' institute, several public libraries, a savings-bank, and a dispensary. Its manufactures are very extensive and flourishing, consisting principally of cotton and woollen goods, with print and bleaching works, which received a great impulse from Kay's invention of the fly-shuttle and dross-box, and the establishment of extensive print-works by the father of the late Sir Robert Peel. That illustrious statesman was born at Chamber Hall in the vicinity. It is connected by railways, as well as by canals, with Manchester, Bolton, &c. In the vicinity are extensive coal mines.

BURY, *Richard de*, see AUNGERVYLE.

BURY ST EDMUNDS, a municipal and parliamentary borough and market-town of England, in the county of Suffolk, on the Larke, 23 miles N.W. of Ipswich, and 71 miles from London. It is governed by a mayor, 6 aldermen, and 18 councillors, and returns two members to parliament. Pop. (1851) 15,900. Registered electors (1851–52) 741. The town is pleasantly situated on a gentle eminence, in a fertile and richly cultivated district, and is clean and well built. It is supposed to be the *Villa Fasestina* of the Romans, and numerous Roman remains have been dug up here. It was the Beodericsworth of the Saxons, and by them made a royal town of East Anglia. Its present name is derived from St Edmund, the king and martyr who was taken prisoner and put to death by the Danes in 780. In 1010 a monastery was founded there by Canute, which for magnificence and splendour surpassed every other establishment of the kind in Britain, with the exception of that of Glastonbury. It was 505 feet long and 212 wide, and contained 12 chapels. The abbot had a seat in parliament, with the power to inflict capital punishment, and judge in all civil causes within the liberty. The privilege of coining was granted to the abbot by Edward the Confessor, and both Edward I. and Edward II. had mints here. The "church" gate, one of the finest specimens of Saxon architecture in the kingdom, and the western gate, erected about the middle of the fourteenth century, with a small portion of the walls, are all that now remain of that magnificent structure. St Mary's church, a fine Gothic edifice, with a beautifully carved roof, was erected in the earlier part of the fifteenth century, and contains the tomb of Mary Tudor, Queen of France. St James's church is also a very fine building, containing several handsome monuments. The free grammar-school, founded by Edward VI., has two scholarships at Cambridge, and six exhibitions to either university. It has a shire-hall where assizes for the county and liberty are held, a guildhall, public library, news and assembly rooms, mechanics' institute, theatre, savings-bank, botanic gardens, county jail, bridewell, a general hospital, and about 100 alms-houses. Market-days Wednesday and Saturday. About a mile below the town the river becomes navigable for barges to Lynn, whence coals and other commodities are brought. In the vicinity is Ickworth, the magnificent seat of the Marquis of Bristol. Sir Nicholas Bacon and Bishop Gardner were born here. It gives the title of Viscount to the Keppel family.

BURYING ALIVE, in ancient Rome, was the punishment of a vestal who violated her vow of chastity. The unhappy priestess was scourged, was attired like a corpse, and then let down into a vault containing some bread, water, milk, oil, a burning lamp, and a couch. Earth was then cast upon her till the pit was filled up. Her paramour was scourged to death in the Forum. Some middle-age writers seem to make burying alive the punishment of a female thief.

BURYING PLACE. The ancients buried out of cities and towns; a usage which we find equally among Jews, Greeks, and Romans. Amongst the last, burying within the walls was expressly prohibited by a law of the twelve tables. The usual places of interment were in the suburbs and fields, but especially by the way sides. We have instances, however, of persons buried in the city; but it was a favour allowed only to a few of singular merit in the commonwealth. Plutarch says, those who had triumphed were indulged in it. Val. Publicola, and C. Fabricius, are said to have had tombs in the Forum; and Cicero adds Tubertus to the number. Lycurgus allowed the Lacedæmonians to bury their dead within the city and round their temples, that the youth, being inured to such spectacles, might be the less terrified with the apprehension of death. Two reasons are alleged why the ancients buried out of cities; the first, an opinion that the sight, touch, or even neighbourhood of a corpse, defiled a man, especially a priest; whence that rule in A. Gellius, that the *flamen dialis* might not on any account enter a place where there was a grave: the second, to prevent the air from being corrupted by the effluvia of putrified bodies, and the buildings from being endangered by the frequency of funeral fires.

Burying in churches was not allowed for the first three centuries after Christ; and the same was severely prohibited by the Christian emperors for many ages afterwards. The first step towards it appears to have been the practice of erecting churches over the graves of some martyrs in the country, and translating the relics of others into churches in the city; the next was, allowing kings and emperors to be buried in the atrium or church-porch. In the sixth century, the people began to be admitted into the churchyards; and some princes, founders, and bishops, into the church. From that time the matter seems to have been left to the discretion of the bishop.

BUSACO, a convent of Portugal, in the province of Beira, on the ridge called the Serra-de-Busaco, 20 miles N.N.E. of Coimbra. Here, on the 27th Sept. 1810, a French force of 65,000 men under Massena was repulsed with great loss in an attack on the position occupied by the English and Portuguese army, amounting to about 40,000, under the Duke of Wellington.

BUSBECQ, AUGIER, GHISLEN DE, a distinguished ambassador and scholar, was born at Commines in 1522, and

educated at the universities of Louvain, Paris, Venice, Bologna, and Padua. He was engaged in several highly important employments and negotiations, and in particular was twice sent ambassador by the king of the Romans to the court of Solyman II. He made a collection of curious inscriptions and manuscripts; and in his second journey to Constantinople he carried with him an artist to make drawings of the rarest plants and animals. In 1562 he was appointed tutor to the sons of Maximilian, then king of the Romans. Busbecq died at St Germain, near Rouen, Oct. 28. 1592. He wrote a Discourse of the State of the Ottoman Empire, and a Relation of his Two Journeys to Turkey, which were much esteemed.

BUSBY, Richard, D.C.L., head master of Westminster school, was born at Lutton in Lincolnshire in 1606. He was educated at the school which he afterwards superintended for so long a period, and first signalized himself by gaining a king's scholarship. From Westminster he removed to Christ Church College, Oxford, where he graduated in 1628. In his thirty-third year he had already become renowned for the obstinate zeal with which he supported the falling dynasty of the Stuarts, and was rewarded for his services with the prebend and rectory of Cudworth, with the chapel of Knowle annexed in the Church of Wells. Next year he became head master of Westminster school. His reputation as a teacher soon became so great that many of the noblest families intrusted their children to his care. He himself once boasted that sixteen of the bishops who then occupied the bench had been birched with his "little rod." No school in England has on the whole produced so many eminent men as Westminster did under the régime of Busby. Among the more illustrious of his pupils may be mentioned South, Dryden, Locke, Prior, and Bishop Atterbury. Busby wrote and edited many works for the use of his scholars. His original treatises (the best of which are his Greek and Latin grammars), as well as those which he edited, have, however, long since fallen into disuse. Busby died in 1695, in his 90th year, and was buried in Westminster Abbey, where his effigy is still to be seen.

BUSCA, a town of Piedmont, on an affluent of the Po, nine miles N.N.W. of Cuneo. It is situated in a fertile district, and produces good wine. Pop. 8000.

BUSCHING, Anthony Frederick, an eminent geographer, born at Stadthagen in Westphalia, Sept. 27, 1724. In his youth he laboured under peculiar disadvantages, till fortunately a clergyman of the name of Hauber, pleased with the promising talents of the young man, undertook to give him gratuitous instruction, and afterwards supplied him with the means of continuing his studies at Halle. There, by his application to learning, and his irreproachable conduct, he acquired numerous friends, and was appointed tutor in the family of the Count de Lynars, who was then going as ambassador to St Petersburg. On this journey he became sensible of the defective state of geographical science, and resolved to devote his life to its improvement. He withdrew as soon as possible from the Count's family, and went to reside at Copenhagen, devoting himself entirely to this new pursuit. In 1752 he published a *Description of the Counties of Sleswig and Holstein*, a work that was much approved. He soon after removed to Gottingen, and married Christiana Dilthey, a young lady of great accomplishments, and the author of a volume of poems. Here, on account of a work which appeared to dissent from some of the Lutheran tenets, he was excluded from the theological chair, for which he had become a candidate. The chagrin occasioned by this disappointment induced him to accept an invitation to the German congregation at St Petersburg. He was employed there, also, in organizing a school, which, under his auspices, soon became one of the most flourishing in the north. This school was superintended by Marshal Munich, who at first showed great favour to Busching; but in consequence of the marshal's unreasonable exactions, Busching announced his intention of returning to Germany. The empress expressed much dissatisfaction at the conduct of Munich, and made high offers to Busching if he would remain; but his resolution was made, and returning to Germany, he went to reside at Altona. Next year, however, he was called to superintend an extensive educational establishment, which had been formed at Berlin under the auspices of Frederick the Great. His writings and example gave a new impulse to education throughout Prussia. He superintended the progress of every pupil, and inspected the minutest details connected with the prosperity of the institution. He also gave lectures on the history of the arts and sciences. This labour did not interrupt the composition of his numerous works. He continued to prosecute his academical labours till a dropsy, under which he had long suffered, terminated his life on the 28th May 1793. Busching was twice married. By the first marriage he had two children, who survived him; by the second he had six, who, except one, all died in infancy.

Few authors, even in Germany, have produced a greater number of works than Busching. The entire number, as enumerated by Meusel in his *Lexicon of German Authors*, amounts to more than a hundred. They may all be classed under the following heads: 1. Geography and History; 2. Education; 3. Religion; 4. Biography. The first class comprehends those upon which his fame chiefly rests. He possessed not, indeed, the geographical genius, if we may so speak, of D'Anville; but he may be regarded as the creator of modern *Statistics*. Devoid of the ornaments of style, his works, from their nature, are rather useful to consult than profitable to read. His great work is the *Neue Erdbeschreibung, New Geographical Description of the Globe*. The first four parts, which comprehend Europe, were published in four successive volumes, from 1754 to 1761, and have been translated into all the European languages. They appeared in English with a preface by Murdoch, in six volumes 4to, London, 1762. He published also, in 1768, the fifth part, being the first volume upon Asia, containing *Asiatic Turkey* and *Arabia*. It displays an immense extent of research, and is generally considered as his masterpiece.

Busching was also the editor of a valuable collection entitled *Magazine for the History and Geography of Modern Times*, 22 vols. 4to, 1767–88; also of a *Journal appropriated to the Notice of Maps*, Berlin, 1773–87.

The elementary works on education published by Busching are very numerous, and have long held a distinguished place, even in a country so eminent as Germany, in this branch of literature. His theological writings are not much esteemed. In biography he wrote a number of articles for the *Historical Magazine*; also *A Collection of Biography*, in six volumes, 1783–9, including a very elaborate life of Frederick the Great.

BUSH, Paul, the first bishop of Bristol, was born in 1490. He became a student in the university of Oxford about 1513, and five years later took the degree of B.A. He afterwards became a brother of the order called *bonhommes*; of which, after studying some time among the friars of St Austin, now Wadham College, he was elected provincial. In that station he had lived many years, when, on account of his great knowledge in divinity and physic, he was appointed chaplain to Henry VIII., and in 1542 to the newly erected episcopal see of Bristol. In consequence of his marriage, he was, on the accession of Mary, deprived of his dignity, and spent the remainder of his life in a private station at Bristol, where he died in 1558. Wood says that Bush, while a student at Oxford, was numbered among the celebrated poets of that university.

He wrote, 1. An Exhortation to Margaret Burgess, wife to John

Burgess, clothier, of King's Wood, in the county of Wilts. London, printed in the reign of Edward VI. 8vo. 2. Notes on the Psalms. 3. Treatise in Praise of the Crosse. 4. Answer to certain Queries concerning the abuse of the Mass, Records, No. 25. 5. Dialogues between Christ and the Virgin Mary. 6. Treatise of Salves and Curing Remedies. 7. A Little Treatise, called the Extirpation of Ignorancy. 8. Carmina diversa.

BUSHEL. See WEIGHTS and MEASURES.

BUSHIRE, ABUSCHEHR, a town of Persia, in the province of Fars, situated in the Persian Gulf. The surrounding country is a parched and barren desert, consisting of brown sand or gray clay and rock, unenlivened by any kind of vegetation. The town, which is of a triangular form, occupies the northern extremity of a peninsula eleven miles long and four broad, and is encircled by the sea on all sides except the south. It is fortified on the land side by a mud wall with round towers. The houses being mostly built of white stone gives the city when viewed from a distance a rather clean and handsome appearance, but on closer inspection the streets are found to be narrow, irregular, ill-paved, and filthy. Almost the only handsome buildings are the sheik's palace and the East India Company's factory. Ships of 300 tons are obliged to lie in the roads six miles from the town. The water immediately east of the town is deep, but its navigation is impeded by a bar, which can only be passed by vessels drawing not more than eight or nine feet of water, except at spring-tides, when there is a rise of from eight to ten feet. It carries on a considerable trade, particularly with Calcutta, Bombay, and Madras. Its imports are indigo, sugar, rice, spices, steel, cotton and woollen goods, coffee, &c.; and its principal exports are raw silk, Kerman wool, shawls, silk goods, carpets, horses, dried fruits, wine, grain, copper, turquoises, pearls, assafœtida, and gall-nuts. The climate is excessively hot, particularly in the months of June, July, and August. The water is very bad; that fit for drinking requires to be brought in goat skins a distance of 16 miles. Pop. variously estimated at from 10,000 to 20,000.

BUSIRIS, a town in Egypt, now called Busyr or Abousir. It is situated on the left bank of the Damietta branch of the Nile, and contains nothing remarkable except the ruins of an ancient temple of Isis. It derived its name from the mythical Busiris, of whom many conflicting accounts are given by ancient writers. The most notable incident in the life of this Busiris is recorded by Apollodorus. For nine consecutive years the Egyptians had suffered from a dearth of corn, which a Cyprian soothsayer, by name Phrasius, declared would cease if Busiris would sacrifice every year a stranger to Jupiter. The soothsayer himself was the first victim of his own prophecy, which was annually obeyed till the arrival of Hercules. When this hero was led to the altar to be sacrificed, he burst his bonds and slew Busiris and his son. The story of Busiris was believed by Greeks and Egyptians to be a myth, and numerous attempts were made by writers of both nations to explain away the tradition.

BUSKIN (*cothurnus*), an ancient kind of boot, which covered the foot, and half of the leg, or even more. Buskins were laced in front so as closely to embrace the leg, and were sometimes ornamented in a very elaborate style. They were chiefly worn by hunters, horsemen, and persons of rank. The cothurnus used in Athenian tragedy had a sole of great thickness for the purpose of increasing the apparent stature of the wearer. In classic authors the word is frequently used as synonymous with tragedy; and it was likewise used to indicate an elevated style in poetry and in painting. See COTHURNUS.

BUSS, an old word signifying a kiss, and to kiss or salute with the lips.

BUSS, a small two-masted vessel, used in the herring fishery, commonly from fifty to seventy tons burden. It has a small shed or cabin at each end.

BUSSORA, BASSORA, BALSORA, or BASRA, a celebrated city of Asia, in the government of Baghdad, situated on the western bank of the Shat-el-Arab, about seventy miles from the mouth of this noble stream, which is navigable to the city for ships of 500 tons burden after passing the bar at its mouth, which however, they can only do at spring-tides. Bussora is surrounded by walls, which are kept in a tolerable state of repair. They have five gates, and are at the lowest computation about seven miles in circuit. Two canals, cut from the river, surround the town on either side, and uniting beyond it on the western side, form a complete ditch to the fortifications. The houses are meanly built, partly of sun-dried and partly of burnt bricks, with flat roofs surrounded by a parapet; and the bazaars, though stocked with the richest merchandise, are miserable structures, not arched as in Baghdad and the Persian towns, but covered with mats laid on rafters of date trees, which hardly afford protection from the scorching rays of the sun. The streets are irregular, narrow, and unpaved, and the town itself is disgustingly filthy. Of the vast area within the walls, the greater proportion is occupied with gardens and plantations of palm trees, intersected by a number of little canals, cleansed twice daily by the ebb and flow of the tide, which rises here about nine feet. The largest of these canals, which approaches the English factory and the palace of the governor situated about two miles from the river, is continually crowded with small vessels. The town has scarcely any public buildings that deserve notice. It has khans and coffee-houses without number, a wretched hummum, and upwards of forty mosques, of which one only is worthy of the name; and this, with the palace of the governor, and the English factory, which are all contiguous to one another, are the only decent buildings in the place. The population is a heterogeneous mixture of all the nations in the East, and consists of Turks, Arabs, Indians, Persians, Armenians, Jacobites, and Jews. The Arabs constitute the principal class; and the Turks, though they are masters of the town, are almost the least numerous.

Bussora is a great emporium of Indian commerce. Six or eight English ships arrive in the course of a year from India; but the chief part of the traffic is carried on in Arabian bottoms; and the merchants of Muscat possess some of the finest vessels that navigate the Indian seas. From various parts of Hindustan, Bussora receives silk, muslin, linen, white and blue cloths for the clothing of the Arabians, gold and silver stuffs, various metals, sandal-wood, and indigo; pearls from Bahrein, and coffee from Mocha; shawls, fruit, and the precious metals from Persia; spices from Java; and European commodities, which are scarce and dear, from different parts. The trade with the interior is conducted by means of caravans to Aleppo and Baghdad, whence the goods are conveyed to Constantinople. The returns are made in Indian goods, bullion, pearls, dates, copper, raw silk, gall-nuts; and the horses, which are very strong and beautiful, are exported in large numbers by the English.

The situation of the town is unhealthy, owing to the inundations of the river, from which noxious exhalations arise; and strangers are commonly attacked by fever after a short residence. The adjoining country is fertile, producing, besides rice, wheat, barley, and dates of different species, a variety of fruits and vegetables, such as apricots, apples, figs, olives, pomegranates, and grapes; and cabbages, broccoli, lettuce, onions, peas, beans, and truffles, in vast quantities. There are whole fields of roses, which the inhabitants cultivate for the purpose of making attar. The liquorice plant also grows amidst the palm groves on the borders of the river.

The city of Bussora was originally founded by Omar, A.D. 636, on a canal eight miles S.W. from its present site, where the town of Zobeir now stands; and its situation was so favourable for commerce that in a few years it became a large and flourishing city. The canal, however, soon be-

came useless, and the city was abandoned. The present city was conquered by the Turks in 1668, and since that period has been the scene of many revolutions. It was taken in 1777, after a siege of eight months, by the Persians under Sadick Khan. In about a year it fell again into the hands of the Turks; who were again deprived of it by the scheik of the Montefik Arabs. The town was in October following recovered by Solyman Pasha, who encountered the scheik on the banks of the Euphrates, and put him to flight; and it has since remained in the hands of the Turks. The population is estimated at 60,000. Long. 47. 34. E. Lat. 30. 32. N.

BUST (Italian *busto*), in *Sculpture*, the head, breast, and shoulders of the human figure.

Felibien observes, that though in painting one may say a figure appears in busto, yet it is not properly called a *bust*, that word being confined to figures in relievo.

The Italians use the word for the trunk of the body from the neck to the hips.

BUSTARD. See Ornithology, *Index*.

BUSTUARII, in *Roman Antiquity*, gladiators who fought about the bustum or funeral pile of a person of distinction, in order that the blood which was spilt might propitiate the infernal gods. This custom was introduced in the room of the more inhuman practice of sacrificing captives at the bustum, or on the tombs of warriors.

BUSTUM, in *Antiquity*, denotes a pyramid or pile of wood whereon the bodies of the deceased were placed in order to be burnt.

The Romans borrowed the custom of burning their dead from the Greeks. The deceased, crowned with flowers, and dressed in the richest habits, was laid on the bustum. Some authors say it was only called *bustum* after the burning, *quasi bene ustum vel combustum:* before the burning it was more properly called *pyra*, during it *rogus*, and afterwards *bustum*. When the body was only burnt there, and buried elsewhere, the place was not properly called *bustum*, but *ustrina*, or *ustrinum*.

Bustum was also figuratively used to denote any tomb; hence *facere bustum, violare bustum, &c.*

BUTCHER, one who slaughters cattle for the use of the table, or who cuts up and retails the same. Among the ancient Romans there were three kinds of established butchers, viz., the *suarii*, who provided hogs; the *pecuarii* or *boarii*, who furnished oxen, &c.; and the *lanii* or *carnifices*, who slaughtered the animals.

Butcher-Bird. See Ornithology, *Index*.

BUTE, John Stuart, third earl of, a British statesman of the time of the second and third Georges, was born in Scotland in 1713. He was educated at Eton, and in his youth was better known as a voluptuary than as a student. He entered parliament as one of the representative peers of Scotland in 1737, and signalized himself by his determined opposition to every measure of the existing government. Soon after he attracted the favourable notice of Frederic Prince of Wales, by whom, in 1738, he was made a knight of the Thistle, and one of the lords of the bedchamber. After the death of that prince he gained a great ascendency over the mind of his son, afterwards George III. For the undue use which he was supposed to have made of his influence, he was bitterly attacked by Junius. On the accession of George III., he was sworn a member of the privy council, and made groom of the stole. In 1762, he became first lord of the treasury, an office which he only retained till the 10th of April of the following year. On that day he suddenly resigned; and the cause of his resignation is not yet clearly ascertained. (For the details of his political life, see Great Britain.) He retired to his mansion near St Albans, where he spent the remainder of his days in literary pursuits. He collected a splendid library, and formed one of the best galleries of Dutch and Flemish pictures in the kingdom. It was to him that Dr Johnson was indebted for his pension; and by his influence a place was secured for Home, the author of Douglas. He died March 10, 1792.

BUTESHIRE, a county on the west coast of Scotland, in the Firth of Clyde, is composed of seven islands, viz. Bute, Arran, Great Cumbrae, Little Cumbrae, Inchmarnock, Holy Island, and Pladda.

Bute, from which the county derives its name, is situated between Long. 4. 51. and 5. 2. W., and Lat. 55. 41. and 55. 43. N., and is 16 miles west from Greenock, 38 miles from Glasgow, and 83 from Edinburgh; but the usual route to these places is about 4 or 5 miles longer. It is about 15 miles long, in a straight line from N.N.W. to S.S.E., and the average breadth is $3\frac{1}{2}$ miles, although it is much indented with bays: in some places it is not above half that breadth, but in other places it is at least a mile broader. It is separated on the north from the district of Cowal in Argyleshire by the Kyles of Bute, which for a considerable distance along the shore are not above half a mile broad. The more southerly part of the island is separated from Ayrshire by the Firth of Clyde, which at that point is from 5 to 7 miles broad; but the channel is much narrowed by the islands of Cumbraes, situated between Bute and Ayrshire, and distant from Bute about 3 miles, but much nearer Ayrshire. Arran lies off the south point of Bute, distant about 6 miles; and Skipness in Argyleshire bounds it on the west at a distance considerably greater. There is considerable uncertainty as to the origin of the name of Bute. Some contend that it is derived from Both, signifying in the Irish tongue a cell; and they ground this on the fact, that it has been so written by ancient authors, and that St Brendan, an Irish abbot, caused a cell to be erected on it in the sixth century. It has been written Both, Bote, Boot, and Botis; but Mr Blain, some time commissary of the isles, and sheriff-substitute of Buteshire, in his manuscript history of Bute, endeavours to show, with considerable ingenuity, that it has been derived from the old British word Ey Budh, or Gaelic word Ey Bhiod, signifying the Island of Corn or Island of Food, from its being more fertile than the adjacent highland countries; and this opinion appears to be still further supported by the fact, that at the time of valuing the teinds, the grain in the island amounted to about 34,700 bolls. The Butemen were anciently called Brandanes, and looking upon themselves as a distinct people, refused to identify themselves either with the highlanders or lowlanders. The island has an area of about 30,000 English acres, of which about two-thirds may be considered as arable; the remainder consists of woods, muirs, mosses, and lakes. There are six lakes in the island. The largest, Loch Fad, extended originally to 138 acres, but is now considerably enlarged by the embankments of the cotton spinning company, whose works are placed on the water flowing from this lake. Ascog Loch is 72 acres in extent. The water flowing from this loch has also an excellent fall for a mill or other public work; but nothing has yet been erected on it except a dye-work, and a carding and wauking mill. It is hoped, however, that it will soon be made more available. Quien Loch covers 54 acres; Greenan Loch, 12 acres; Loch Dhu, or Black Loch, 9 acres; and Lochantarbh, 5 acres. The climate is more mild, genial, and healthy, than in any other part of the west of Scotland. It is frequently compared to that of Devonshire, to which it is in some respects considered as superior. The lofty mountains of Arran and Argyle skirt it on the west and south, and break the clouds coming from the Western Ocean, so that they pass over Bute with a discharge of comparatively but little of their contents, and less rain falls here than on the rest of the west coast of Scotland. In summer the air is kept cool by the sea breeze, and in winter the same cause prevents intense frost; while snow seldom falls to the depth of twelve inches, and very rarely remains above two or three days on the ground. The winds most prevalent blow from the south and west.

Agriculture, under the fostering care of the late Marquis of Bute, has of late years made considerable progress in the island, especially in the middle and southern divisions. The soil in the southern half of the island is light and sandy; in the more northern it is of a clayey nature. The land is generally well subdivided with ditches and white-thorn hedges. Crops of all kinds common in the lowlands are produced in Bute.

Freestone and coal are both found in the island, but neither to any great extent. Several attempts have been made to discover a good working vein of coals, but hitherto without success. Slate and lime, however, abound. The slate has been principally wrought on the estate of Kames, formerly the seat of the deceased Sir William M'Leod Bannatyne, one of the lords of session, but now possessed by James Hamilton, Esq. The lime has been chiefly wrought in the south end of the island, in the parish of Kingarth; and that manufactured there is considered as equal, if not superior, in point of adhesiveness, to the far-famed Arden lime of Lanarkshire, when properly wrought; and it is much cheaper, though not so white in the colour. Inexhaustible beds of shells are found on the west side of the island, and considerable quantities of sea-weed are driven in upon the shores. The rocks in the north end are chiefly mica, clay, and chlorite slate, intersected with quartz and trap. Whinstone is chiefly found near the town of Rothesay, and sandstone stretches along from thence to the south.

Excellent banks for fishing are found round the island; and the herring fishery is prosecuted vigorously by the inhabitants, especially by residents in Rothesay.

The Marquis of Bute is the chief proprietor of the island. His seat, Mountstuart, is beautifully situated on the east side of the island, about four miles from Rothesay. The real rent of his property in the island is about L.9000, including L.440 of feu-duty for ground feued chiefly within the burgh of Rothesay. The other proprietors of any extent are James Hamilton, Esq. of Kames, rent L.1500; Robert Thom, Esq. of Ascog, L.700; M'Conechy of Ambrisbeg, L.70; James M'Kay of Garrachty, L.70; and George Campbell, Esq. of Dunoon, whose lands of Ardbeg, let on long building leases, are now nearly covered with villas, and form substantially a part of the town of Rothesay.

The burgh of Rothesay, the capital of the island and shire, is beautifully situated at the head of a deep bay on the N.E. side of the island, where there is safe anchorage-ground for vessels of any size, in any wind, and room enough to contain a very large fleet. The territory of the burgh is about nine miles in circumference, extending fully a mile beyond the town on the east, south, and west sides. The burgh has an extensive harbour built in 1822 at an expense of L.6000, and on which large sums have been since expended. It is now in an excellent state. The shipping belonging to the port was at one time upwards of 4000 tons, but it has decreased of late, owing to the decline of the herring trade. There is a large spinning factory, consisting of two mills, in Rothesay, driven by water from Loch Fad; and it may be worthy of notice, that the second mill erected in Scotland for the spinning of cotton was upon this water only about fifty-five years ago, when the business was carried on with the strictest secrecy. The house then used was a thatched building, which is still standing. There are three power-loom factories in Rothesay, in one of which cotton is also spun. Numerous steam-boats ply daily to and from Glasgow and the intermediate ports. These convey the mail; and in the summer season there are generally two mails in the day.

The town has of late been rapidly increasing, and handsome new streets are building. The places of worship in Rothesay are the parish church, situated on a gentle eminence about a quarter of a mile from the town; another Established church close to the town; three Free churches (the predominant denomination), one being Gaelic; one Reformed Presbyterian, one United Presbyterian; one Episcopalian; one Baptist; and about two miles from Rothesay there is a Roman Catholic chapel. The County Buildings are situated in Rothesay, and contain a large and handsome courtroom with the requisite offices attached. The prison is under the same roof, and affords good accommodation for proper classification of the prisoners. The courts are held in Rothesay. The sheriff court is held every Tuesday and Friday, and the burgh court every Thursday. There is a local police act, under which the burgh magistrates act as judges and try petty delinquencies. The ruins of an ancient castle, which was once the residence of the kings of Scotland, are situated in the middle of the town. The castle originally consisted of a circular court, 138 feet in diameter, surrounded by a wall eight feet thick and seventeen feet high, with battlements. It had four towers and was surrounded by a wet ditch. It is supposed to have been built about the year 1100, though the precise date is not known. It is first mentioned in history in 1228. Heulbec, king of the Isles, was killed in besieging this castle in 1263. It was taken possession of by the English during the reign of John Baliol, but surrendered to Robert the Bruce in 1311. King Robert the Second built a palace adjoining the castle, and frequently took up his residence in it betwixt 1376 and 1398, when he created his eldest son Prince David Duke of Rothesay, a title which the king's eldest son still bears. This was the first dukedom conferred in Scotland. On the 12th January 1400 Robert granted the charter of erection of the burgh of Rothesay. He died in the castle of Rothesay on 4th April 1406, and was buried in the abbey of Paisley. This castle was burned by the Earl of Argyll's brother in 1685, and has since remained in ruins. The population of the burgh of Rothesay in 1851 was 7014, besides upwards of 300 seamen belonging to registered vessels, not included in the census.

The island is divided into three parishes, Rothesay, Kingarth, and North Bute; the first containing a population (1851) of 7354, including the burgh; the second a population of 1007, and the third a population of 1025, making the whole population of the island 9386, exclusive of seamen absent when the census was taken. In Kingarth parish there is, besides the parish church, a Free church at Ascog, and in the parish of North Bute there is a Free church at Port Bannatyne. Lord Bute is the patron of all of the parish churches.

The island is highly esteemed, and is much resorted to as sea-bathing quarters in the summer season; and many invalids are induced, by the mildness of the climate, to reside there during the winter.

There are several remains of druidical monuments on the island, but the chief or most entire is at Langalchorid, in the parish of Kingarth. At Dunagoil, in this parish, there is a vitrified fort, and the remains of an old church, and burying-ground, where, until after the Reformation, the two sexes were not allowed to intermingle. Near this church there is a circular inclosure called the Devil's Cauldron, where penance was wont to be performed. As this rite of superstition is somewhat singular, we shall describe it. Transgressors were imprisoned in this terrene purgatory for a given time, which, it may be readily conceived, was proportioned to the magnitude of the offences committed, being sometimes for several days and nights together. The priest threatened eternal punishment to the whole party if but one of their number fell asleep. To provide against this, the penitents were furnished with a sharp instrument, with which they pricked each other when inclined to somnolency.

There are three villages in the island; Port Bannatyne, situated at the head of Kames Bay, about two and a half miles from Rothesay, which is of some extent, has a good quay, and a pretty numerous fishing population; Ker-

rycroy, near Mountstuart, the seat of the Marquis of Bute; and Kilcatten Bay, situated on the south side of the island. The natives formerly spoke the English and Gaelic languages indifferently, but English is now chiefly spoken.

Arran is situated about six miles south of Bute. It is very mountainous. Goatfell, a mountain situated about the centre of the island, is upwards of 2945 feet high; and some others approach to that height. There is a remarkably fine view from this mountain on all sides, whence is seen part of the Atlantic Ocean, Ireland, the counties of Ayr, Renfrew, Argyle, and Bute, the Firth of Clyde, Loch Fine, and other scenery both beautiful and picturesque. There are many druidical remains and monumental stones on the island. Fingal's Cave is still pointed out; and tradition says that Ossian died on this island. The island is about twenty miles long and eleven broad, and contains about 106,000 English acres, of which only 15,000 are arable. Abundance of game and some wild deer are found on the mountains, which are either bare rocks, or only covered with heath and fern, but including magnificent glens. There is comparatively little wood in the island, except near Brodick Castle, where there are fine old woods and thriving young plantations. A large addition has but lately been made to Brodick Castle, and improvements are in progress which, when completed, will, combined with the mixed grand and beautiful scenery, make Brodick Castle one of the most attractive seats in Scotland. The climate in winter is mild, but generally moist. The whole island, except a small estate, belongs to the Duke of Hamilton, in which family it has been for several centuries. The other proprietor is Captain Fullarton, of Kilmichael, descended of a very ancient family formerly bearing the name of MacLoy. The roads are for the most part very good, having been chiefly made by the parliamentary commissioners several years ago; and the expense of repairs is defrayed partly by the exchequer, and partly by the proprietors, in terms of the act 59th Geo. III. cap. 135. The herring fishery is prosecuted to a considerable extent, but this is almost wholly done by means of boats and other small vessels. There are two excellent harbours in the island, Lamlash and Loch Ranza, but without piers of any extent. There is a small pier at Brodick, but the bay is not well sheltered for anchorage. An extensive pier was commenced at Lamlash in the reign of Queen Anne, and a considerable part erected, but it was afterwards neglected; and all the stones above the water have from time to time been removed for building or other purposes, so that now the foundation can scarcely be traced; and the only landing place is a small jetty recently built. The island produces barley, bear, oats, peas, beans, potatoes, and turnips. The islanders were long addicted to illicit distillation, a practice which has been given up, owing chiefly, it is believed, to the strong laws enacted against it, and the firmness with which they are executed. Agriculture was at one time neglected, every farm being occupied by a society of tenants, among whom the arable part of the farm was divided in small lots, while the pasturage grounds and moors were a common under one herd. The farms are now well subdivided, and some of them are large and well cultivated by tenants of enterprise and skill. There was many years ago a great emigration from this island to America, although the inhabitants were strongly attached to their native soil. The language chiefly spoken by the natives is Gaelic, but they are advancing in the knowledge of English. The islanders are all Protestants, and strongly attached to the Free Church of Scotland, about 9-10ths of them belonging to that denomination. Christianity is said to have been introduced here by St Molios, a disciple of St Columba. The island is divided into two parishes, Kilbride and Kilmory, and has also two chapels. There are three places of worship belonging to the Free Church of Scotland. The largest parish is named Kilmory, and contained (1851) 3414 inhabitants; the other parish named Kilbride, contains 2533 inhabitants, making the population of the island 5947, besides a few seamen belonging to registered vessels, being a decrease from 6427 (census 1831), attributed to emigration. Arran is highly celebrated for its mineralogy. (See Jameson's *Mineralogy of the Scottish Isles*, Headrich's *Survey of Arran*, and Dr M'Culloch's works.) Granite, rock crystal, quartz, and small-grained granite, are abundant in the northern division of the island. Mica slate and granite unite at Catacoal. Gneiss, micaceous schist, and pudding-stone, are abundant at Glenrosa. Quartz is found in all kinds of crystallization, in beds of clay slate and in other situations. Greenstone, sandstone resting on clay slate, basalt, trap, and limestone, are abundant. Pitchstone is found on the south, with pearlstone, ironstone, and porphyry; also flint, agate, siliceous spar, jaspar, and various beautiful crystals.

Great Cumbrae is situated in the Firth of Clyde betwixt Ayrshire and the Island of Bute. It is the property of the Marquis of Bute and the Earl of Glasgow. It is about two and a half miles long, and one and a half broad, and measures about 2500 acres, one-half of which is arable. It has a gentle ascent of about 400 feet from the sea to the centre of the island. The village of Millport is situated on the S.W. side of the island, opposite to which there is safe anchorage-ground (which, however, is not easily reached), and a small harbour is formed with a stone pier. Millport is increasing very fast, both in extent and population. Many neat villas have lately been built, and it has become a favourite watering place, as the bathing ground is excellent. There is a college belonging to the Scotch Episcopal Church. It is a handsome Gothic building with a chapel and spire, and attached to it are an excellent garden and pleasure grounds, which are open to the public at certain hours. There are a provost, dean, and choristers, and the necessary establishment for education. The college was erected and endowed, it is understood, chiefly at the expense of the Honourable Mr Boyle, the brother of Lord Glasgow. There is in Millport a residence of the Earl of Glasgow called The Garrison. It is occupied by the countess-dowager, and is a neat Gothic building, with pleasure grounds. The great defect in Cumbrae is the absence of roads: there is only one made road, and it is a bad one. The farms are of some size, and the agriculture is good. The climate is mild and healthy. The island abounds with lime and freestone. Considerable quantities of the freestone are exported, but the lime is seldom wrought. There are two basaltic rocks on the east side of the island, called Reppel Walls. It forms one parish, and has one Established church and a Free church. The population in 1851 was 1266, besides seamen belonging to registered vessels.

Little Cumbrae lies about half a mile south of Great Cumbrae. It is the property of the Earl of Eglinton. It is about a mile in length, and half a mile in breadth. Ecclesiastically Little Cumbrae is attached to the parish of Killin in Ayrshire, while civilly and politically it is in Buteshire. Rabbits are very plentiful on this island. A lighthouse was erected in 1750 on the highest point of the island, but it was found that the fogs obscured the light; it was therefore removed to a lower situation. Three or four families live on it. The ruins of a castle are situated on the south side. The ascent from the shore is over rocks, which rise one above another like steps of stairs. There are several caves in the island, two of them very large. The extent of one of these is not known, but the other is thirty-two feet square, and six feet in height.

Inchmarnoch is a low-lying, small, beautiful island, situated about a mile west from Bute. It takes its name from a chapel built on it, dedicated to St Marnoch, and which had a burying-ground attached. The ruins were visible till very lately, when they were removed by the rude hands

Butler.

of a farmer. It is about a mile long and half a mile broad, and is divided into three farms, and nearly one-half is arable. It is the property of the Marquis of Bute, and abounds in sea shell or marl. The inhabitants acknowledge the spiritual jurisdiction of the parish of Rothesay, although it was long considered as belonging to Saddel in Argyleshire, from the monks of St Marnoch being attached to the convent of Saddel; and still the minister of Kerry in Argyleshire derives a portion of his stipend from this island.

Pladda is a small island, which lies about a mile S.E. from Arran, on which there is a lighthouse, which directs the mariner to the Cumbrae light.

Holy Island is a small island situated in the mouth of Lamlash Bay, in Arran, and helps to form that safe and capacious harbour. There is one house upon it, and the island forms a farm of some value.

The valued rent of the county in Scots money is L.15,042, 13s. 10d. The lands belong to ten proprietors. The valuation Scots of the Marquis of Bute's land is L.8066, 5s. 4¼d.; that of the Duke of Hamilton is L.4955, 11s. Nearly one-fourth of the lands in the county is entailed. The real rent of the county in 1849, was L.40,570 including house property. Of the thirty-three shires of Scotland, Bute was the twelfth in point of precedency in the Scottish parliament rolls and all public processions, though not entitled to that rank in point of valuation. It sent two members to parliament before the union; from that time till the passing of the Reform bill, Bute and Caithness returned a member alternately; now Bute returns a member for itself. The burgh of Rothesay is included in the county constituency, having a separate constitution for municipal purposes. The county constituency is about 483. The family of Bute were hereditary sheriffs of the county for upwards of 360 years, until the jurisdictions were taken away in 1748. They were also lords of the regality of Bute. The Marquis of Bute is heritable coroner of the island of Bute, and keeper of the castle of Rothesay. By a recent statute the counties of Dumbarton and Bute are combined as one sheriffdom, under the jurisdiction of the same sheriff, but each county has a sheriff-substitute and other officials. Lord James Stuart, the uncle of the Marquis of Bute, is the lord-lieutenant. Criminals usually tried before the justiciary court are sent to the circuit court at Inveraray. Buteshire sends ten assizers to that circuit court. The islands of Bute and Cumbrae were granted by the sovereign of Scotland, at an early period, to the lord high steward; and when they fell under the power of Norway, the monarch of that country gave Bute and certain other islands to Reginald, king of Man. After the marriage of Alexander VI., lord high steward, with Jean, daughter and heiress of Angus, one of the grandsons of the king of Man, the islands of Bute, Arran, and Cumbrae became a favoured part of the patrimony of the lord high steward, between whom and the people a strong attachment subsisted; and they were, by way of distinction, called the Lord High Steward's Brandanes. It is probable that this name was derived from St Brandane, who flourished in the eleventh century. Sir John Stuart of Bute, from whom the family of Bute descended, was son to King Robert II., and received from his father the office of heritable sheriff, as well as an estate of lands in Bute and Arran. In the year 1544 the English burned the greater part of Bute and Arran. The shire of Bute contains 171 English square miles, or 109,375 English acres; and the population in 1851 amounted to 16,608, besides seamen belonging to registered vessels.

BUTLER (French *bouteillier*, from *bouteille*, a bottle, *i. e.* the *bottler*), a servant or officer in the houses of the wealthy, whose chief business is to take charge of the wine, plate, &c. The title was anciently applied in the court of France to an officer corresponding to the grand échanson or great cup-bearer of later times.

Butler.

Butler, *Charles*, an ingenious and learned writer, born in 1559, at High Wycomb in Buckinghamshire. He entered of Magdalen Hall, Oxford, whence, after taking a degree in arts, he was translated to Magdalen College. He afterwards became master of the free school at Basingstoke, and curate of a neighbouring parish. He was promoted about the year 1600 to the vicarage of Lawrence-Wotton, in the same county, and there he died in 1647. He published a book entitled "The Principles of Music in singing and setting; with the twofold use thereof, ecclesiastical and civil;" 4to, London, 1636. This very learned and entertaining book is highly praised by Dr Burney in his *History of Music*. His various works are enumerated by Wood in the *Athenæ Oxonienses*. Among these is a curious English Grammar, published in 1633, in which he proposes a scheme of regular orthography, and makes use of peculiar characters, some borrowed from the Saxon, and others of his own invention; and of this imagined improvement he has made use in all his tracts.

Butler, *James*, Duke of Ormond, was born at London in 1610. To the personal interest which King James took in his early education may be attributed that devotion to the Stuart dynasty, and to the principles of the Protestant faith, that distinguished him through life. In his 20th year he entered the army, and two years later, on the death of his grandfather, he succeeded to the earldom of Ormond. His talents attracted the notice of Strafford, at that time lord-lieutenant of Ireland; and by the influence of this nobleman he was appointed to the command of the army intended for the suppression of the Irish rebellion. Though he checked the progress of the insurgents, and gained many advantages over them, his efforts were so much impeded by the jealous interference of Strafford, that Charles granted him an independent commission under the Great Seal, and raised him to a marquisate. In 1644, three years after the death of Strafford, he was appointed lord-lieutenant of Ireland, a situation rendered doubly difficult by the insubordination of the Irish themselves, and by the intrigues of the English parliament. In 1647 he returned to England; and though his administration was publicly approved of by Charles, the state of affairs was such that he resolved to secure his safety by a temporary residence in France. After the king's death he returned to Ireland, and availing himself of the reaction that had taken place in consequence of that event, he caused Charles II. to be proclaimed. Cromwell, however, soon after landed in Ireland, and Ormond once more retired to France and joined the exiled family of the late king. At the Restoration he not only recovered his estates, but was rewarded for his many services with the title of duke. In 1662 he was again appointed lord-lieutenant of Ireland, and retained this office for seven years. In 1670 he narrowly escaped assassination at the hands of the notorious Colonel Blood. At the request of the king, however, he forgave his intended assassin, upon whom no punishment was ever inflicted. In 1667 he was once more appointed lord-lieutenant of Ireland, and governed that country with marked ability and success till 1685, when he resigned his office and returned to England. He died at his seat in Dorsetshire in 1688, and was buried in Westminster Abbey. His son, "the gallant" Ossory, had predeceased him by eight years. Many details of his personal history, together with an admirable delineation of his character, will be found in Sir Walter Scott's *Peveril of the Peak*.

Butler, *Joseph*, Bishop of Durham—one of the most profound and original thinkers this or any country ever produced—well deserves a place among the *dii majores* of English philosophy; with Bacon, Newton, and Locke.

The following brief sketch will comprise an outline of his life and character, some remarks on the peculiarities of his genius, and an estimate of his principal writings.

He was born at Wantage, in Berkshire, May 18, 1692

His father, Thomas Butler, had been a linen-draper in that town, but before the birth of Joseph, who was the youngest of a family of eight, had relinquished business. He continued to reside at Wantage, however, at a house called the Priory, which is still shown to the curious visitor.

Young Butler received his first instructions from the Rev. Philip Barton, a clergyman, and master of the grammar-school at Wantage. The father, who was a Presbyterian, was anxious that his son, who early gave indications of capacity, should dedicate himself to the ministry in his own communion, and sent him to a Dissenting academy at Gloucester, then kept by Mr Samuel Jones. "Jones," says Professor Fitzgerald, with equal truth and justice, "was a man of no mean ability or erudition;" and adds, with honourable liberality, "could number among his scholars many names that might confer honour on any university in Christendom."[1] He instances among others Jeremiah Jones, the author of the excellent work on the *Canon;* Secker, afterwards Archbishop of Canterbury; and two of the most learned, acute, and candid apologists for Christianity England has produced—Nathaniel Lardner and Samuel Chandler.

The academy was shortly afterwards removed to Tewkesbury. While yet there, Butler first displayed his extraordinary aptitude for metaphysical speculation in the letters he sent to Clarke on two supposed flaws in the reasoning of the recently published *à priori* Demonstration; one respecting the proof of the Divine *omnipresence*, and the other respecting the proof of the *unity* of the "necessarily existent Being." It is but just to Clarke to say that his opponent subsequently surrendered both objections. Whether the capitulation be judged strictly the result of logical necessity, will depend on the estimate formed of the value of Clarke's proof of the truths in question;—truths which are happily capable of being shown to be so, independently of any such *à priori* metaphysical demonstration. In this encounter, Butler showed his modesty not less than his prowess. He was so afraid of being discovered, that he employed his friend Secker to convey his letters to the Gloucester post-office, and to bring back the answers.

About this time he began to entertain doubts of the propriety of adhering to his father's Presbyterian opinions, and consequently, of entering the ministry of that communion; doubts which at length terminated in his joining the Church of England. His father, seeing all opposition vain, at length consented to his repairing to Oxford, where he was entered as a commoner of Oriel College, March 17, 1714. Here he early formed an intimate friendship with Mr Edward Talbot, second son of the Bishop of Durham, a connection to which his future advancement was in a great degree owing.

The exact period at which Butler took orders is not known, but it must have been before 1717, as by that date he was occasionally supplying Talbot's living, at Hendred, near Wantage. In 1718, at the age of twenty-six, he was nominated preacher at the Rolls, on the united recommendation of Talbot and Dr Samuel Clarke.

At this time the country was in a ferment. What is called the "Bangorian Controversy," and which originated in a sermon of Bishop Hoadley, "On the Nature of Christ's Kingdom" (a discourse supposed to imperil "all ecclesiastical authority") was then raging. One pamphlet which that voluminous controversy called forth has been attributed to Butler. "The external evidence, however, is," as Mr Fitzgerald judges, "but slight; and the internal for the negative at least equally so." This writer says, "On the whole, I feel unable to arrive at any positive decision on the subject." Readers curious respecting it may consult Mr Fitzgerald's pages, where they will find a detail of the circumstances which led to the publication of the pamphlet, and the evidence for and against its being attributed to Butler.

In 1721, Bishop Talbot presented Butler with the living of Haughton, near Dorkington, and Secker (who had also relinquished nonconformity, and after some considerable fluctuations in his religious views, had at length entered the church), with that of Haughton-le-Spring. In 1725 the same liberal patron transferred Butler to the more lucrative benefice of Stanhope.

He retained his situation of preacher at the Rolls till the following year (1726); and before quitting it published the celebrated "Fifteen Sermons" delivered there; among the most profound and original discourses which philosophical theologian ever gave to the world. As these could have been but a portion of those he preached at the Rolls, it has often been asked what could have become of the remainder? We agree with Mr Fitzgerald in thinking that the substance of many was afterwards worked into the "Analogy." That many of them were equally important with the "Fifteen" may be inferred from Butler's declaration in the preface,—that the selection of these had been determined by "circumstances in a great measure accidental." At his death, Butler desired his manuscripts to be destroyed; this he would hardly have done, had he not already rifled their chief treasures for his great work. Let us hope so at all events; for it would be provoking to think that discourses of equal value with the "Fifteen" had been wantonly committed to the flames.

After resigning his preachership at the Rolls, he retired to Stanhope, and gave himself up to study and the duties of a parish priest. All that could be gleaned of his habits and mode of life there has been preserved by the present Bishop of Exeter, his successor in the living of Stanhope eighty years after; and it is little enough. Tradition said that "Rector Butler rode a black pony, and always rode very fast; that he was loved and respected by all his parishioners; that he lived very retired, was very kind, and could not resist the importunities of common beggars, who, knowing his infirmity, pursued him so earnestly, as sometimes to drive him back into his house as his only escape." The last fact the bishop reports doubtful; but Butler's extreme benevolence is not so.

In all probability, Butler in this seclusion was meditating and digesting that great work on which his fame, and what is better than fame, his usefulness, principally rests—"The Analogy." "In a similar retirement," says Professor Fitzgerald, "The Ecclesiastical Polity of Hooker, The Intellectual System of Cudworth, and The Divine Legation of Warburton—records of genius 'which posterity will not willingly let die'—were ripened into maturity." Queen Caroline once asked Archbishop Blackburne whether Butler was not "dead?" "No," said he, "but he is *buried.*" It was well for posterity that he was thus, for a while, entombed.

He remained in this meditative seclusion seven years. At the end of this period, his friend Secker, who thought Butler's health and spirits were failing under excess of solitude and study, succeeded in dragging him from his retreat. Lord Chancellor Talbot, at Secker's solicitation, appointed him his chaplain in 1733; and in 1736 a prebendary of Rochester. In the same year, Queen Caroline, who thought her court derived as much lustre from philosophers and divines as from statesmen and courtiers—who had been the delighted spectator of the argumentative contests of Clarke and Berkeley, Hoadley and Sherlock—appointed Butler clerk of the closet, and commanded "his attendance every evening from seven till nine."

It was in 1736 that the celebrated "Analogy" was published, and its great merits immediately attracted public

[1] *Life of Butler*, prefixed to Professor Fitzgerald's very valuable edition of the *Analogy*, Dublin, 1849. The memoir is derived chiefly from Mr Bartlett's more copious "Life;" it is very carefully compiled, and is frequently cited in the present article.

attention. It was perpetually in the hands of his royal patroness, and passed through several editions before the author's death. Its greatest praise is that it has been almost universally read, and never answered. "I am not aware," says Mr Fitzgerald, "that any of those whom it would have immediately concerned, have ever attempted a regular reply to the 'Analogy;' but particular parts of it have met with answers, and the whole, as a whole, has been sometimes unfavourably criticised." Of its merits, and precise position in relation "to those whom it immediately concerns," we shall speak presently.

Some strange criticisms on its general character in Tholuck's *Vermischte Schriften*, showing a singular infelicity in missing Butler's true "*standpunkt*," as Tholuck's own countrymen would say, and rather unreasonably complaining of obscurity, considering the quality of German theologico-philosophical style in general, are well disposed of by Professor Fitzgerald (Pp. xlvii.–l.)

About this time Butler had some correspondence with Lord Kaimes on the *Evidences of Natural and Revealed Religion.* Kaimes requested a personal interview, which Butler declined in a manner very characteristic of his modesty and caution. It was "on the score of his natural diffidence and reserve, his being unaccustomed to oral controversy, and his fear that the cause of truth might thence suffer from the unskilfulness of its advocate."

Hume was a kinsman of Lord Kaimes, and when preparing his treatise of *Human Nature* for the press, was recommended by Lord Kaimes to get Butler's judgment on it. "Your thoughts and mine," says Hume, "agree with respect to Dr Butler, and I should be glad to be introduced to him." The interview, however, never took place, nor was Butler's judgment obtained. One cannot help speculating on the possible consequences. Would it have made any difference?

In the year 1737, Queen Caroline died, but on her deathbed recommended her favourite divine to her husband's care. In 1738 Butler was accordingly made Bishop of Bristol, in place of Dr Gooch, who was translated to Norwich. This seems to have been a politic stroke of Walpole, who "probably thought," says Fitzgerald, "that the ascetic rector of Stanhope was too unworldly a person to care for the poverty of his preferment, or perceive the slight which it implied." In the reply, however, in which Butler expresses his sense of the honour conferred, he shows that he understood the position of matters very clearly. The hint he gave seems to have had its effect, for in 1740 the King nominated him to the vacant Deanery of St Paul's, whereupon he resigned Stanhope, which he had hitherto held *in commendam.* The revenues of Bristol, the poorest see, did not exceed L.400.

A curious anecdote of Butler has been preserved by his domestic chaplain, Dr Tucker, afterwards Dean of Gloucester. He says;—"His custom was, when at Bristol, to walk for hours in his garden in the darkest night which the time of the year could afford, and I had frequently the honour to attend him. After walking some time, he would stop suddenly and ask the question, 'What security is there against the insanity of individuals? The physicians know of none; and as to divines, we have no data, either from Scripture or from reason, to go upon relative to this affair.' 'True, my Lord, no man has a lease of his understanding any more than of his life; they are both in the hands of the Sovereign Disposer of all things.' He would then take another turn, and again stop short—'Why might not whole communities and public bodies be seized with fits of insanity, as well as individuals.' 'My Lord, I have never considered the case, and can give no opinion concerning it.' 'Nothing but this principle, that they are liable to insanity, equally at least with private persons, can account for the major part of those transactions of which we read in history.' I thought little of that odd conceit of the bishop at that juncture; but I own I could not avoid thinking of it a great deal since, and applying it to many cases."

In 1747, on the death of Archbishop Potter, it is said that the primacy was offered to Butler, who declined it with the remark that "it was too late for him to try to support a falling church." If he really said so, it must have been in a moment of despondency, to which his constitutional melancholy often disposed him. No such feeling, at all events, prevented his accepting the bishopric of Durham in 1750, on the death of Dr Edward Chandler. About the time of his promotion to this dignity, he was engaged in a design for consolidating and extending the Church of England in the American colonies. With this object he drew up a plan marked by his characteristic moderation and liberality; the project, however, came to nothing.

Soon after his translation to the see of Durham, Butler delivered and published his charge on the Use and Importance of External Religion, which gave rise, in conjunction with his erection of a "white marble cross" over the communion table in his chapel at Bristol, and one or two other slight circumstances, to the ridiculous and malignant charge of popery;—a charge, as Mr Fitzgerald observes, "destitute of a shadow of positive evidence, and contradicted by the whole tenor of Butler's character, life, and writings."

The revenues from his see were lavishly expended in the support of public and private charities,[1] while his own mode of life was most simple and unostentatious. Of the frugality of his table, the following anecdote is proof:—"A friend of mine, since deceased, told me," says the Rev. John Newton, "that when he was a young man, he once dined with the late Dr Butler, at that time Bishop of Durham; and, though the guest was a man of fortune, and the interview by appointment, the provision was no more than a joint of meat and a pudding. The bishop apologized for his plain fare, by saying, that it was his way of living; 'that he had been long disgusted with the fashionable expense of time and money in entertainments, and was determined that it should receive no countenance from his example.'" No prelate ever owed less to politics for his elevation, or took less part in them. If he was not "wafted to his see of Durham," as Horace Walpole ludicrously said, "on a cloud of metaphysics," he certainly was not carried there by political intrigue or party manœuvres. He was never known to speak in the House of Peers, though constant in his attendance there.

He had not long enjoyed his new dignity before symptoms of decay disclosed themselves. He repaired to Bath in 1752, in hope of recovering his health, where he died, June 16, in the 60th year of his age.

His face was thin, and pale, but singularly expressive of placidity and benevolence. "His white hair," says Hutchinson,[2] "hung gracefully on his shoulders, and his whole figure was patriarchal." He was buried in the cathedral of Bristol, where two monuments have been erected to his memory. They record in suitable inscriptions (one in Latin by his chaplain, Dr Foster, and the other in English by the late Dr Southey) his virtues and genius. Though epitaphs, they speak no more than simple truth.

[1] Butler must have been of a naturally munificent as well as benevolent disposition. He was extremely fond, it appears, of *planning* and *building;* a passion not always very prudently indulged, or without danger, in early days, of involving him in difficulties; from which, indeed, on one occasion Secker's intervention saved him. He spent large sums in improving his various residences. It was probably in the indulgence of the love of ornamentation to which this passion led, that the "marble cross" and other imprudent symbols which were so ridiculously adduced to support the charge of popery, originated.

[2] *History of Durham,* vol. i. p. 578; cited in Fitzgerald's "Life."

A singular anecdote is recorded of his last moments. As Mr Fitzgerald observes, "it wants direct testimony," but is in itself neither uninstructive nor incredible, for a dying hour has often given strange vividness and intensity to truths neither previously unknown nor uninfluential. It is generally given thus:—"When Bishop Butler lay on his death-bed, he called for his chaplain, and said, 'Though I have endeavoured to avoid sin, and to please God, to the utmost of my power; yet, from the consciousness of perpetual infirmities, I am still afraid to die.' 'My Lord,' said the chaplain, 'you have forgotten that Jesus Christ is a Saviour.' 'True,' was the answer, 'but how shall I know that he is a Saviour for me?' 'My Lord, it is written, Him that cometh unto me, I will in no wise cast out.' 'True,' said the bishop, 'and I am surprised, that though I have read that scripture a thousand times over, I never felt its virtue till this moment; and now I die happy.'"

The genius of Butler was almost equally distinguished by subtilty and comprehensiveness, though the latter quality was perhaps the most characteristic. In his *juvenile* correspondence with Clarke—already referred to—he displays an acuteness which, as Sir James Mackintosh observes, "neither himself nor any other ever surpassed;" an analytic skill, which, in earlier ages, might easily have gained him a rank with the most renowned of the schoolmen. But in his mature works, though they are everywhere characterized by subtle thought, he manifests in combination with it qualities yet more valuable;—patient comprehensiveness in the survey of complex evidence, a profound judgment and a most judicial calmness in computing its several elements, and a singular constructive skill in combining the materials of argument into a consistent logical fabric. This "architectural power" of mind may be wholly or nearly wanting, where the mere analytic faculty may exist in much vigour. The latter may even be possessed in vicious excess, resulting in little more than the disintegration of the subjects presented to its ingenuity. Synthetically to reconstruct the complex unity, when the task of analysis is completed, to assign the reciprocal relations and law of subordination of its various parts, requires something more. Many can take a watch to pieces, who would be sorely puzzled to put it together again.

Butler possessed these powers of analysis and synthesis in remarkable equipoise. What is more, he could not only recombine, and present in symmetrical harmony, the elements of a complex unity when capable of being subjected to an exact previous analysis,—as in his remarkable sketch of the Moral Constitution of Man,—but he had a wonderfully keen eye for detecting remote analogies and subtle relations where the elements are presented intermingled or in isolation, and insusceptible of being presented as a single object of contemplation previous to the attempt to combine them. This is the case with the celebrated "Analogy." In the Sermons on Human Nature, he comprehensively surveys that nature as a *system* or *constitution;* and after a careful analysis of its principles, affections, and passions, views these elements in combination, endeavours to reduce each of these to its place, assigns to them their relative importance, and deduces from the whole the law of subordination—which he finds in the Moral Supremacy of Conscience, as the key-stone of the arch—the ruling principle of the "Constitution." In the Analogy, he gathers up and combines from a wide survey of scattered and disjointed facts, those resemblances and relations on which the argument is founded, and works them into one of the most original and symmetrical logical creations to which human genius ever gave birth. The latter task was by far the more gigantic of the two. To recur to our previous illustration, Butler is here like one who puts a watch together without having been permitted to take it to pieces—from the mere presentation of its disjointed fragments. In the former case he resembled the physiologist who has an entire animal to study and dissect; in the latter he resembled Cuvier, constructing out of *disjecta membra*—a bone scattered here and there—an organized unity which man had never seen except in isolated fragments.

All Butler's productions—even his briefest—display much of this "architectonic" quality of mind; in all he not only evinces a keen analytic power in discerning the "differences" (one phase of the philosophic genius, according to Bacon, and hardly the brightest), but a still higher power of detecting the "analogies" and "resemblances of things," and thus of showing their relations and subordination. These peculiarities make his writings difficult, but it makes them profound, and it gives them singular completeness.

It is not difficult to assign the precise sphere in which Butler, with eminent gifts for abstract science in general, felt most at home. Facts show us, not only that there are peculiarities of mental structure which prompt men to the pursuit of some of the great objects of thought and speculation rather than others—peculiarities which circumstances may determine and education modify, but which neither circumstances nor education can do *more* than determine or modify; but that even in relation to the very same subject of speculation, there are minute and specific varieties of mind, which prompt men to addict themselves rather to this part of it than to that. This was the case with Butler. Eminently fitted for the prosecution of metaphysical science in general, it is always the *philosophy of the moral nature of man* to which he most naturally attaches himself, and on which he best loves to expatiate. Neither Bacon nor Pascal ever revolved more deeply the phenomena of our moral nature, or contemplated its inconsistencies—its intricacies—its paradoxes—with a keener glance or more comprehensive survey; or drew from such survey reflections more original or instructive. As in reading Locke the young metaphysician is perpetually startled by the palpable apparition, in distinct sharply-defined outline, of facts of consciousness which he recognises as having been partially and dimly present to his mind before—though too fugitive to fix, too vague to receive a name; so in reading Butler, he is continually surprised by the statement of moral facts and laws, which he then first adequately recognises as true, and sees in distinct vision face to face. It is not without reason that Sir James Mackintosh says of the sermons preached at the Rolls, "that in them Butler has taught truths more capable of being exactly distinguished from the doctrines of his predecessors, more satisfactorily established by him, more comprehensively applied to particulars, more rationally connected with each other, and therefore more worthy of the name of *discovery*, than any with which we are acquainted."

His special predilections for the sphere of speculation we have mentioned are strikingly indicated in his choice of the *ground* from which he proposes to survey the questions of morals. "There are two ways," says he in the preface to his three celebrated sermons on Human Nature, "in which the subject of morals may be treated. One begins from inquiring into the abstract relations of things; the other, from a matter of fact, namely, what the particular nature of man is, its several parts, their economy or constitution; from whence it proceeds to determine what course of life it is, which is correspondent to this whole nature." As might be expected, from the tendencies of his mind, he selects the *latter* course.

The powers of *observation* in Butler must have been, in spite of his studious life and his remarkable habits of abstraction, not much inferior to his keen faculty of introspection, though this last was undoubtedly the main instrument by which he traced so profoundly the mysteries of our nature. There have doubtless been other men, far less pro-

found, who have had a more quick or more vivid perception of the peculiarities of character which discriminate individuals, or small classes of men (evincing, after all, however, not so much a knowledge of *man*, as a knowledge of *men*); still, the masterly manner in which Butler often sketches even these, shows that he must have been a very sagacious observer of those phenomena of human nature which presented themselves from *without*, as well as of those which revealed themselves from *within*. In general, however, it is the characteristics of *man*, the generic phenomena of our nature, in all their complexity and subtilty, that he best loves to investigate and exhibit. The spirit of his profound philosophy is meantime worthy both of the Christian character and the ample intellect of him who excogitated it. It is the very reverse of that of the philosophical satirist or caricaturist; however severely just to the foibles, the inconsistencies, the corruptions of our nature, it is a philosophy everywhere compassionate, magnanimous, and philanthropic. Its tone, indeed, like that of the philosophy of Pascal (though not shaded with the same deep melancholy), is entirely modulated by a profound conviction of the frailty and ignorance of man, of the little we know compared with what is to be known,—and of the duty of humility, modesty, and caution in relation, to all those great problems of the universe, which tempt and exercise man's ambitious speculations. His constant feeling, amidst the beautiful and original reasonings of the "Analogy," is identical with that of Newton, when, reverting at the close of life to his sublime discoveries, he declared that he seemed only like a child who had been amusing himself with picking up a few shells on the margin of the ocean of universal truth, while the infinite still lay unexplored before him. In a word, it is the feeling, not only of Pascal and of Newton, but of all the profoundest speculators of our race, whose grandest lesson from all they learned, was the vanishing ratio of man's knowledge to man's ignorance. Hence the immense value (if only as a discipline) of a careful study of Butler's writings, to every youthful mind. They cannot but powerfully tend to check presumption, and teach modesty and self-distrust.

The feebleness of Butler's imagination was singularly contrasted with the *inventive* and *constructive* qualities of his intellect, and the facility with which he detected and employed "analogies" in the way of argument. He is, indeed, almost unique in this respect. Other philosophic minds (Bacon and Burke are illustrious examples), which have possessed similar aptitudes for "analogical" reasoning, have usually had quite sufficient of the kindred activity of imagination to employ "analogies" for the purpose of poetical illustration. If Butler possessed this faculty by nature in any tolerable measure, it must (as has been the case with some other great thinkers) have been repressed and absorbed by his habits of abstraction. His defect in this respect is, in some respects, to be regretted, since unquestionably the illustrations which imagination would have supplied to argument, and the graces it would have imparted to style, would have made his writings both more intelligible and more attractive. It is said that once, and once only, he "courted the muses," having indited a solitary "acrostic to a fair cousin," who for the first, and as it seems, the only time, inspired him with the tender passion. But, as one of his biographers says, we have probably no great reason to lament the loss of this fragment of his poetry.

Butler's composition is almost as destitute of the vivacity of wit as of the graces of imagination. Yet is he by no means without that dry sort of humour which often accompanies very vigorous logic, and, indeed, is in some sense inseparable from it; for the neat detection of a sophism, or the sudden and unexpected explosion of a fallacy, produces much the same effect as wit on those who are capable of enjoying close and cogent reasoning. There is also a kind of simple, grave, satirical pleasantry, with which he sometimes states and refutes an objection, by no means without its piquancy.

As to the complaint of obscurity, which has been so often charged on Butler's style, it is difficult to see its justice in the sense in which it has been usually preferred. He is a *difficult* author, no doubt, but he is so from the close packing of his thoughts, and their immense generality and comprehensiveness; as also from what may be called the *breadth* of his march, and from occasional lateral excursions for the purpose of disposing of some objection which he does not formally mention, but which might harass his flank; it certainly is not from indeterminate language or (ordinarily) involved construction. All that is really required in the reader, *capable* of understanding him at all, is to do just what he does with lyrical poetry (if we may employ an odd, and yet in this one point, not inapt comparison); he must read sufficiently often to make all the transitions of thought familiar, he must let the mind dwell with patience on each argument till its entire scope and bearing are properly appreciated. Nothing certainly is wanting in the method or arrangement of the thoughts; and the diction seems to us selected with the utmost care and precision. Indeed, as Professor Fitzgerald justly observes, a collation of the first with the subsequent editions of the "Analogy" (the variations are given in Mr Fitzgerald's edition) will show, by the nature of the alterations, what pains Butler bestowed on a point on which he is erroneously supposed to have been negligent. In subjects so abstruse, and involving so much generality of expression, the utmost difficulty must always be experienced in selecting language which conveys *neither more nor less* than what is intended; and this point Butler must have laboured immensely; it may be added, successfully, since he has at least produced works which have seldom given rise to disputes as to his meaning. Though he may be difficult to be understood, few people complain of his being liable to be *mis*understood. In short, it may be doubted whether any man of so comprehensive a mind, and dealing with such abstract subjects, ever condensed the results of twenty years' meditations into so small a compass, with so little obscurity. No doubt greater amplification would have made him more pleasing, but it may be questioned whether the perusal of his writings would have been so useful a discipline; and whether the truths he has delivered would have fixed themselves so indelibly as they now generally do in the minds of all who diligently study him. It is the result of the very activity of mind his writings stimulate and demand. But, at any rate, if precision in the use of language, and method and consecutiveness in the thoughts, are sufficient to rebut the charge of obscurity, Butler is not chargeable with the fault in the ordinary sense. We must never forget what Whately in his rhetoric has so well illustrated; that perspicuity is a "relative quality." To the intelligent, or those who are willing to take sufficient pains to understand, Butler will not seem chargeable with obscurity. The diction is plain, downright Saxon-English, and the style, however homely, has, as the writer just mentioned observes, the great charm of transparent simplicity of purpose and unaffected earnestness.

The immortal "Analogy" has probably done more to silence the objections of infidelity than any other ever written from the earliest "apologies" downwards. It not only most critically met the spirit of unbelief in the author's own day, but is equally adapted to meet that which *chiefly* prevails in all time. In every age, some of the principal, perhaps *the* principal, objections to the Christian Revelation, have been those which men's *preconceptions* of the Divine character and administration—of what God *must* be, and of what God *must* do—have suggested against certain facts in the sacred history, or certain doctrines it reveals. To show

the objector then (supposing him to be a theist, as nine-tenths of all such objectors have been), that the very same or similar difficulties are found in the structure of the universe and the divine administration of it, is to wrest every *such* weapon completely from his hands, if he be a fair reasoner and remain a theist at all. He is bound by strict logical obligation either to show that the parallel difficulties do *not* exist, or to show how he can solve them, while he *cannot* solve those of the Bible. In default of doing either of these things, he ought either to renounce all *such* objections to Christianity, or abandon theism altogether. It is true, therefore, that though Butler leaves the alternative of atheism open, he hardly leaves any other alternative to nine-tenths of the theists who have objected to Christianity.

It has been sometimes said by way of reproach, that Butler *does* leave that door open; that his work does not confute the atheist. The answer is, that it is not its object to confute atheism; but it is equally true, that it does not diminish by one grain any of the arguments against it. It leaves the evidence for theism—every particle of it—just where it was. Butler merely avails himself of facts which exist, undeniably exist (whether men be atheists or theists), to neutralize a certain class of objections against Christianity. And as the exhibition of such facts as form the pivot on which Butler's argument turns, does not impugn the truth of theism, but leaves its conclusions, and the immense preponderance and convergence of evidence which establish them just as they were, so it is equally true that Butler has sufficiently guarded his argument from any perversion; for example, in Part I. chap. vi., and Part II. chap. viii. He has also with his accustomed acuteness and judgment shown that, even on the principles of atheism itself, its confident assumption that, *if* its principles be granted, a future life—future happiness—future misery—is a dream,—cannot be depended on; for since men have existed, they may again; and if in a bad condition now, in a worse hereafter. It is not, on such an hypothesis, a whit more unaccountable that man's life should be renewed or preserved, or perpetuated for ever, than that it should have been originated at all. On this point, he truly says, "That we are to live hereafter, is just as reconcileable with the scheme of atheism, and as well to be accounted for by it, as that we are now alive, is; and therefore nothing can be more absurd than to argue from that scheme, that there can be no future state."

It has been also alleged that the analogy only "*shifts* the difficulty from revealed to natural religion," and that "atheists might make use of the arguments and have done so." The answer is, not only (as just said) that the arguments of Butler leave every particle of the evidence for theism just where it was, and that he has sufficiently guarded against all abuse of them; but that the *facts*, of which it is so foolishly said that the atheist *might* make ill use, had always been the very arguments which he *had* used, and of which Butler only made a new and beneficial application. The objections with which he perplexes and baffles the deist, *he* did not give to the atheist's armoury; he took them from thence, merely to make an unexpected and more legitimate use of them. The atheist had never neglected such weapons, nor was likely to do so, previous to Butler's adroit application of them. The charge is ridiculous; as well might a man, who had wrested a stiletto from an assassin to defend himself, be accused of having put the weapon into the assassin's hands! It was there before; he merely wrested it thence. It is just so with Butler.

Further: we cannot but think that the conclusiveness of Butler's work as against its true object *The Deist*, has often been underrated, by many even of its genuine admirers. Thus Dr Chalmers, for instance, who gives such glowing proofs of his admiration of the work, and expatiates in a congenial spirit on its merits, affirms that "those overrate the power of analogy who look to it for any very distinct or positive contribution to the Christian argument. To repel objections, in fact, is the great service which analogy has rendered to the cause of Revelation, and it is the *only service* which we seek for at its hands."[1] This, abstractedly, is true; but, *in fact*, considering the *position* of the bulk of the objectors, that they have been invincibly persuaded of the truth of theism, and that their objections to Christianity have been exclusively or chiefly of the kind dealt with in the "Analogy," the work is much more than an *argumentum ad hominem;* it is not simply of negative value. To such *objectors* it logically establishes the truth of Christianity, or it forces them to recede from theism, which the bulk will not do. If a man says, "I am invincibly persuaded of the truth of proposition A, but I cannot receive proposition B, because objections α, β, γ are opposed to it; if these were removed, my objections would cease;" then, if you can show that α, β, γ equally apply to the proposition A, his reception of which, he says, is based on invincible evidence, you do really compel such a man to believe that not only B *may* be true, but that it *is* true, unless he be willing (which few in the parallel case are) to abandon proposition A as well as B. This is precisely the condition in which the majority of deists have ever been, if we may judge from their writings. It is usually the *à priori* assumption, that certain facts in the history of the Bible, or some portions of its doctrine, are unworthy of the Deity, and incompatible with his character or administration, that has chiefly excited the incredulity of the deist; far more than any dissatisfaction with the positive evidence which substantiates the Divine origin of Christianity. Neutralize these objections by showing that they are *equally* applicable to what he declares he cannot relinquish—the doctrines of theism; and you show him, if he has a particle of logical sagacity, not only that Christianity may be true, but that it is so; and his only escape is by relapsing into atheism, or resting his opposition on other objections of a very feeble character in comparison, and which, probably, few would ever have been contented with alone; for *apart* from those objections which Butler repels, the historical evidence for Christianity,—the evidence on behalf of the integrity of its records, and the honesty and sincerity of its founders,—showing that they *could* not have constructed such a system if they *would*, and *would* not, supposing them impostors, if they *could*,—is stronger than that for any fact in history.

In consequence of this position of the argument, Butler's book, to large classes of objectors, though practically an *argumentum ad hominem*, not only proves Christianity *may* be true, but in all logical fairness proves it *is* so. This he himself, with his usual judgment, points out. He says: "And objections, which are equally applicable to both natural and revealed religion, are, properly speaking, answered by its being shown that they are so, *provided the former be admitted to be true.*"

The praise which Mackintosh bestows on this great work, is alike worthy of it and himself. "Butler's great work, though only a commentary on the singularly original and pregnant passage of Origen, which is so honestly prefixed to it as a motto, is, notwithstanding, the most original and profound work extant in any language, on the *Philosophy of Religion.*[2] The favourite topics of the "Sermons" are, of course, largely insisted on in the "Analogy;" such as the

[1] *Prelections on Butler*, &c., p. 7.

[2] A far different and utterly inconsistent judgment in all respects is reported, in his "Life," to have fallen from him. But as Professor Fitzgerald shows, it is so strangely, and, indeed, amusingly contrary to the above, that it must have been founded on some mistake of something that had been said in conversation.

"ignorance of man;" the restrictions which the limitations of his nature and his position in the universe should impose on his speculations; his subjection to "probability as the guide of life;" the folly and presumption of pronouncing, *à priori*, on the character and conduct of the Divine Ruler from our contracted point of view, and our glimpses of but a very small segment of his universal plan. These topics Butler enforces with a power not less admirable than the sagacity with which he traces the analogies between the "Constitution and Course of Nature" and the disclosures of "Divine Revelation." These last, of course, form the staple of the argument; but to enforce the proper deductions from them, the above favourite topics are absolutely essential.

It has been sometimes, though erroneously, surmised, that Butler was considerably indebted to preceding writers. That in the progress of the long deistical controversy many theologians should have caught glimpses of the same line of argument, is not wonderful. The constant iteration by the English deists of that same class of difficulties to which the "Analogy" replies, could not fail to lead to a partial perception of the powerful instrument it was reserved for Butler effectually to wield. It has been here as with almost every other great intellectual achievement of man; many minds have been simultaneously engaged by the natural progress of events *about* the same subject of thought; there have been "coming shadows" and "vague anticipations," perhaps even simultaneous inventions or discoveries; and then ensues much debate as to the *true* claimants. Thus it was in relation to the calculus, the analysis of water, the invention of the steam-engine, and the discovery of Neptune.

In the present case, however, there can be no doubt that the merit of the systematic construction of the entire argument rests with Butler. Nor would it have much detracted from his merit, even if he had derived far larger fragments of the fabric from his contemporaries than we have any reason to believe he did. They would have been but single stones; the architectural genius which brought them from their distant quarries and polished them, and wrought them into a massive edifice, was his alone.

Professor Fitzgerald has truly remarked, that the work of Dr James Foster against Tindal (an author Butler evidently has constantly in his eye), presents some curious parallelisms with certain passages of the "Analogy;" we have ourselves noted in Conybeare's reply to the same infidel writer (published six years before the "Analogy"), other parallelisms not less striking. But it seems quite improbable that Butler should have derived aid from any such sources, since his work was being excogitated for many years before it was published; nay, as we have seen, it may be conjectured that he largely transfused into it portions of the Sermons delivered so long before at the Rolls, and of which a far greater number must have been preached than the fifteen he published; so that, perhaps, it is more near the truth to say, that contemporary writers had been indebted to him than he to them.

The "pregnant sentence" from Origen, however, is not the only thing which may have suggested to Butler his great work. Berkeley, in a long passage of the "Minute Philosopher," cited by Mr Fitzgerald, clearly lays down the *principle* on which such a work as the "Analogy" might be constructed.

The spirit of the "Analogy" is admirable. Though eminently controversial in its origin and purpose; and though the author must constantly have had the deistical writers of the day in his eye, his work is calm and dignified, and divested of every trace of the controversial spirit. He does not even mention the names of the men whose opinions he is refuting; and if their systems had been merely some new minerals, or aerolites dropped upon the world from some unknown sphere, he could not have analysed them with less of passion.

Of Butler's ethical philosophy, as expounded especially in the "Sermons on Human Nature," Sir James Mackintosh's remarks prefixed to this Encyclopædia supersede further notice in the present brief article. But it may be remarked in general of the Sermons preached at the Rolls, that though not so much read (if we except, perhaps, the three just mentioned) as the Analogy, they are to the full as worthy of being read; they deserve all that is so strikingly said of them in the Preliminary Dissertation. Some of them fill one with wonder at the sagacity with which the moral paradoxes in human nature are investigated and reconciled. Take, for example, the sermon on Balaam. The first feeling in many a mind on reading the history in the Old Testament is, that man *could* not so act in the given circumstances. We doubt if ever any man deeply pondered the sermon of Butler, in which he dwells on the equally unaccountable phenomena of human conduct, less observed, indeed, only because more observable—and questioned any longer man's powers of self-deception, even to such feats of folly and wickedness as are recorded of the prophet.

The editions of Butler's writings, separately or altogether, have been numerous, and it is impossible within the limits of this article to specify them; still less to do justice to the *literature* which they have produced. His commentators have been many and most illustrious; seldom has a man who wrote so little, engaged so many great minds to do him homage, by becoming his exponents and annotators. It may be permitted, however, to mention with deserved honour the Remarks of Sir James Mackintosh prefixed to this Encyclopædia; the "Prelections" of Dr Chalmers on the "Analogy;" the valuable "Essay" of Dr Hampden "On the Philosophical Evidence of Christianity;" some beautiful applications of Butler's principle in Whately's "Essays on the Peculiarities of Christianity;" and the admirable edition of the "Analogy" by Professor Fitzgerald, which is enriched by many very acute and judicious notes, and by a copious and valuable index.

A very neat and convenient edition of Butler's entire works, in two volumes, 8vo, has been issued from the Clarendon press. (H. R.)

Butler, *Samuel*, the author of *Hudibras*, was the son of a respectable Worcestershire farmer, and was born at Strensham in that county, February 13, 1612. He passed some time at Cambridge, but was never matriculated in that university. Returning to his native county, he lived some years as clerk to a justice of peace, and also applied himself to history, poetry, and painting. Being recommended to Elizabeth, Countess of Kent, he enjoyed in her house not only the use of all kinds of books, but the conversation of the illustrious Selden, who often employed Butler to write letters and translate for him. He lived also some time with Sir Samuel Luke, a gentleman of an ancient family in Bedfordshire, and a famous commander under Oliver Cromwell; and he is supposed at this time to have written, or at least to have planned, his celebrated *Hudibras*, and under that character to have ridiculed the knight. The poem itself furnishes this key in the first canto, where Hudibras says—

> "'Tis sung, there is a valiant Mameluke
> In foreign land yclep'd —— ——
> To whom we oft have been compar'd
> For person, parts, address, and beard."

After the Restoration, Butler was appointed secretary to the Earl of Carbury, lord-president of Wales, who appointed him steward of Ludlow Castle when the court was revived there. No one proved a more generous friend to him than the Earl of Dorset and Middlesex, to whom it was owing that the court relished his *Hudibras*. He had promises of a good place from the Earl of Clarendon, but they were never accomplished; though the king was so much pleased with the poem as often to quote it pleasantly in conversation. It is indeed said that Charles ordered him the

sum of L.3000; but the sum being expressed in figures, somebody through whose hands the order passed reduced it, by cutting off a cypher, to L.300, and though it passed the offices without fees, it proved not sufficient to pay what he then owed; so that Butler benefited but little by the king's bounty. During the latter years of his life he was reduced to almost absolute want, and his fate might have been that of the ill-starred Otway, had not the kind interference of Mr Longueville, a bencher of the Inner Temple, prevented such a catastrophe. This gentleman likewise erected a monument in memory of Butler, after his death, which took place in 1680. Granger observes, that Butler "stands without a rival in burlesque poetry. His *Hudibras*," he adds, "is in its kind almost as great an effort of genius as the *Paradise Lost* itself. It abounds with uncommon learning, new rhymes, and original thoughts. Its images are truly and naturally ridiculous. There are many strokes of temporary satire, and some characters and allusions which cannot be discovered at this distance of time."

BUTRINTO (the ancient *Buthrotum*), a fortified maritime town of European Turkey in Albania, immediately opposite the island of Corfu. It stands at the mouth of a stream three or four miles in length, connecting the lake of Vatzindro (the ancient *Pelodes*), with the bay. It is said to have been founded by Helenus, the son of Priam; and on the conquest of Epirus by the Romans, it became a Roman colony. The Roman walls, which still exist, are about a mile in circumference, and are mixed up with remains both of later and of Hellenic work. Pop. about 2000.

BUTT, a measure of wine, containing two hogsheads, or 126 wine gallons. See Pipe.

BUTTER, the unctuous substance obtained from milk by churning. It was not till a late period that the Greeks became acquainted with butter. The Romans used it as a medicine, but not as food. According to Beckmann, the discovery of butter belongs neither to the Greeks nor to the Romans. The former, he thinks, derived their knowledge of butter from the Scythians, the Thracians, and Phrygians; and the latter from the people of Germany. For the process of butter-making, see Dairy.

The ancient Christians of Egypt burnt butter in their lamps instead of oil; and in the Roman churches it was anciently allowed, during Christmas time, to burn butter instead of oil, on account of the great consumption of the latter at that season.

Butter, in the old chemistry, was the term applied to various preparations; as butter of antimony (sesquichloride of antimony); butter of arsenic (sublimated muriate of arsenic); butter of bismuth (sublimated muriate of bismuth); butter of tin (sublimated muriate of tin); butter of zinc (sublimated muriate of zinc).

Butterfly. See Entomology, *Index*.

Buttermilk, milk from which the butter has been separated by churning.

Butter-Tree, a species of *Bassia*, found in Africa. It yields a substance like butter, which is called by Park *Shea butter*.

BUTTERIS, an instrument of steel set in a handle, for paring the hoof of a horse.

BUTTEVANT, a market-town of Ireland, county of Cork, on the Awbeg, 137 miles from Dublin by the Great Southern and Western railway. It was formerly a walled town of some importance, and has remains of two castles and an abbey, founded about the end of the thirteenth century. Buttevant has extensive infantry barracks. Pop. (1851) 1531.

BUTTON, a knob, or small ball; or a similar article used for fastening or ornamenting different parts of dress. These latter are formed of a great variety of materials and shapes. The method of making solid metal buttons is as follows:—The metal with which the moulds are intended to be covered is first cast into small ingots, and then flatted into thin plates by the flattening mill; these are cut into small round pieces proportional to the size of the mould they are intended to cover, by means of proper punches, on a block of wood covered with a thick plate of lead. Each piece of metal thus cut out of the plate is reduced into the form of a button by beating it successively in several concave moulds, with a convex puncheon of iron, always beginning with the shallowest cavity of the mould, and proceeding to the deeper, till the plate has acquired the intended form; and the better to manage so thin a plate, ten, twelve, and sometimes even twenty-four, are formed to the cavities, or concave moulds, at once; often annealing the metal during the operation, to make it more ductile. This plate is generally called by workmen the *cap of the button*.

The form being thus given to the plates or caps, the intended impression is struck on the convex side, by means of a similar iron puncheon, in a kind of mould engraven *en creux*, either by the hammer or a press, similar to that used in coining. The mould in which the impression is to be made is of a diameter and depth suitable to the sort of button intended to be struck in it; each kind requiring a particular mould. Between the puncheon and the plate is placed a thin piece of lead, called by workmen a *hob*, which greatly contributes to take off all the strokes of the engraving; the lead, by reason of its softness, easily giving way to the parts which have relief, and as easily insinuating itself into the traces or indentures.

The plate thus prepared makes the cap or shell of the button. The lower part is formed of another plate, in the same manner, but much flatter, and without any impression. To the last or under plate is soldered a small eye, made of wire, by which the button is to be fastened.

The two plates being thus finished, they are soldered together with soft solder, and then turned in a lathe. Generally indeed a wooden mould is used instead of the under plate; and in order to fasten it, a thread or gut is passed across through the middle of the mould, and the cavity between the mould and the cap is filled with cement, in order to render the button firm and solid; for the cement entering all the cavities formed by the relief of the other side, sustains it, prevents its flattening, and preserves its boss or design.

BUTTRESS, a kind of abutment built archwise, or a mass of stone or brick, serving to support the side of a building or wall externally, when very high or loaded with a heavy superstructure. Buttresses are chiefly used against the angles of steeples and on the outside of such buildings as have heavy roofs, which would be apt to thrust out the walls if unsupported in this manner. They are sometimes placed for a support and abutment against the feet of arches that are turned across great halls in old palaces, abbeys, &c.

Flying buttresses are such as are carried across by an arch from one wall to another. See Architecture.

BUTZOW, a city in the duchy of Mecklenburg-Schwerin, on the Warnow, 16 miles from Rostock. It was formerly the seat of the bishops of Schwerin; and in 1760 a university was founded here, which, however, in 1789, was united with that of Rostock. It manufactures paper, playing-cards, linen, and brandy. Pop. 4050.

BUXAR, a town of Hindustan, in the province of Bahar, district of Shahabad, situated on the south bank of the Ganges. The fort, though of small size, commanded the Ganges, but is now dismantled. This place is distinguished by a celebrated victory gained there on the 23d October 1764 by the British forces under Major (afterwards Sir Hector) Munro, over the united armies of Sujah ud Dowlah and Cossim Ali Khan. The action raged from nine o'clock till noon, when the enemy gave way. Pursuit was, however, frustrated by Sujah ud Dowlah sacrificing a part of his army to the safety of the remainder. A bridge of boats had

been constructed over a stream about two miles distant from the field of battle, and this the enemy destroyed before their rear had passed over. Through this act two thousand troops were drowned, or otherwise lost; but destructive as was this proceeding, it was, says Major Munro, "the best piece of generalship Sujah ud Dowlah showed that day, because if I had crossed the rivulet with the army, I should either have taken or drowned his whole army in the Caramnassa, and come up with his treasure and jewels, and Cossim Ali Khan's jewels, which I was informed amounted to between two and three millions." Lat. 25. 32., Long. 84. 3.

BUXTON, a market-town and fashionable watering-place of Derbyshire, in the parish of Bakewell, and hundred of High Peak, 31 miles N.W. of Derby, and 160 miles from London. It is situated in a deep valley surrounded by hills of considerable elevation, except on the side where the Wye, which rises near this, has its exit. It consist of an old and new town, the former more elevated than the latter, and consisting of one wide street with some good inns and lodging-houses; but most of the buildings are low and mean. In the centre of the market-place is an old cross. The new town is much more elegant, and contains many handsome buildings. Among these is the crescent, a noble range of buildings in the Grecian style, erected by the late Duke of Devonshire in 1779–86, at a cost of L.120,000, and containing hotels, ball-room, lodging-houses, bank, library, arcade, promenade, and an extensive range of stables with riding gallery behind. At the west end of the crescent is the old hall, built by the Earl of Shrewsbury in the reign of Queen Elizabeth, once the residence of Mary Queen of Scots. The church is a handsome edifice, built in 1812 by the Duke of Devonshire. There are numerous public and private baths. The springs, which were known to the Romans, are inclosed in a small Grecian building, and supply hot and cold water within a few inches of each other. They are saline, sulphurous, and charged with nitrogen, and flow at the rate of 60 gallons a minute. They are found useful in cutaneous and nervous complaints, indigestion, gout, and rheumatism. Besides these there is a chalybeate spring behind the crescent, the water of which when mixed with that of the other springs, proves purgative. The "Bath Charity," supported by subscription, is for the maintenance for one month of poor invalids who may require to use the waters. The season extends from June to October, and from 12,000 to 14,000 visitors arrive annually. The public walks are numerous and tastefully laid out. In the vicinity are Pool's Hole (a vast stalactitic cavern), and the Diamond Hill, so called from the profusion of crystals dispersed through the soil. Pop. (1851) 1235, mostly engaged in the manufacture of alabaster, spar, and other ornaments, and in lime-burning.

BUXTON, *Jedediah*, a prodigy of skill in numbers, was born in 1704, at Elmton, near Chesterfield, in Derbyshire. Although his father was schoolmaster of the parish, and his grandfather had been the vicar, his education had been so neglected that he could not write; and with respect to any other knowledge but that of numbers, he seemed always as ignorant as a child. How he came first to know the relative proportions of numbers, and their progressive denominations, he did not remember; but on such matters, his attention was so constantly rivetted, that he frequently took no cognizance of external objects, and when he did, it was only with reference to their numbers. If any space of time was mentioned, he would soon afterwards reduce it to minutes; and if any distance, he would assign the number of hair-breadths, without any question being asked or any calculation expected by the company. He worked out every question after his own method, without any external aid, or even understanding the common rules of arithmetic as taught in the schools. He would stride over a piece of land or a field, and tell the contents of it almost as exactly as if it had been measured by the chain. In this manner he measured the whole lordship of Elmton, consisting of some thousand acres, and gave the contents not only in acres, roods, and perches, but even in square inches. After this, for his own amusement, he reduced them into square hair-breadths, computing forty-eight to each side of the inch. His memory was so great, that in resolving a question he could leave off and resume the operation again at the same point after the elapse of a week, or even of several months. His perpetual application to figures prevented the smallest acquisition of any other knowledge. On his return from church, it never appeared that he had brought away one sentence, his mind, having been busied in his favourite occupation. His wonderful faculty was tested in 1754 by the Royal Society of London, who acknowledged their satisfaction by presenting him with a handsome gratuity. In this visit to the metropolis, the great object of his curiosity was to see the king and royal family; but in this he was disappointed by their recent removal to Kensington. He was taken to see the tragedy of Richard III. performed at Drury Lane theatre; but his mind was solely employed in his usual occupation. He attended to Garrick only to count the words he uttered. During the dance, he fixed his attention upon the number of steps; and he declared that the innumerable sounds produced by the musical instruments had perplexed him beyond measure. Jedediah returned to the place of his birth, where he died about the age of seventy.

BUXTORF, JOHN, a famous Hebrew scholar, was born at Camen in Westphalia, Dec. 25, 1564. He became professor of the Hebrew and Chaldee languages at Basle, where he was settled as a Calvinist minister. He died of the plague, Sept. 13, 1629. His principal works are—his *Rabbinical Bible*, 4 vols. fol.; *Talmudical Lexicon; Hebrew Concordance;* a small but excellent *Hebrew Grammar*, the best edition of which is that of Leyden, 1701, revised by Leusden; *A Treatise of the Hebrew Grammar; Institutio epistolaris Hebraica; De Abbreviaturis Hebraeorum;* &c.

BUXTORF, *John*, the son of the preceding, and a learned professor of the oriental languages at Basle, distinguished himself, like his father, by his knowledge of the Hebrew language, and his rabbinical learning. He died at Basle in 1664, aged sixty-five. His principal works are, his translation of the *More Nevochim* of Maimonides, and the *Liber Cosri;* A Chaldee and Syriac Lexicon; An Anti-critique against Capellus; A treatise on the Hebrew Points and Accents, also against Capellus. See CAPELLUS.

BUYING, the act of making a purchase, or of acquiring the property of a thing for a certain price.

Buying the Refusal is giving money for the right of purchasing at a fixed price at a stated time; chiefly used in dealing for shares in stock. This is sometimes called by the cant phrase of *buying the bear*.

BUZOT, a town of the province of Valencia, in Spain, about ten miles from Alicant, in a most romantic situation. It is celebrated for its warm baths, and for the kermes collected from the *quercus coccifera*.

BUZZARD. See ORNITHOLOGY, *Index*.

BYNG, GEORGE, Lord Viscount Torrington, a distinguished English admiral, was born in 1663. At the age of fifteen he went to sea as a volunteer with the king's warrant. After being several times advanced, he was in 1702 raised to the command of the Nassau, a third rate, and was at the taking and burning of the French fleet at Vigo; and the next year he was made rear-admiral of the red. In 1704 he served in the grand fleet sent to the Mediterranean under Sir Cloudsley Shovel as rear-admiral of the red; and reduced Gibraltar. He was in the battle of Malaga, which followed soon afterwards; and for his gallantry in that action received the honour of knighthood. In 1718 he was made admiral and commander-in-chief of the fleet, and was

Bynkershoek || Byron.

sent with a squadron into the Mediterranean for the protection of Italy. This commission he executed so well, that the king made him a handsome present, and sent him full powers to negotiate with the princes and states of Italy, as there should be occasion. He procured the emperor's troops free access into the fortresses which still held out in Sicily, sailed afterwards to Malta, and brought out the Sicilian galleys, and a ship belonging to the Turkey company. Soon afterwards he received an autograph letter from the Emperor Charles VI., accompanied with his portrait, set round with large diamonds, as a mark of his grateful sense of his services. It was entirely owing to his advice and assistance that the Germans retook the city of Messina in 1719, and destroyed the ships which lay in the basin; an achievement which completed the ruin of the naval power of Spain. The Spaniards being much distressed, offered to quit Sicily; but the admiral declared that the troops should never be suffered to depart from the island till the king of Spain had acceded to the quadruple alliance. And to his conduct it was entirely owing that Sicily was subdued, and his Catholic Majesty forced to accept the terms prescribed him by the quadruple alliance. After performing so many signal services, he was received by the king with the most gracious expressions of favour and satisfaction; and made rear-admiral of England and treasurer of the navy, a member of the privy-council, Baron Byng of Southill, in the county of Bedford, Viscount Torrington in Devonshire, and one of the knights companions of the bath upon the revival of that order. In 1727 George II., on his accession to the crown, placed him at the head of naval affairs, as first lord of the admiralty. He died January 15, 1733, in the seventieth year of his age, and was buried at Southill, in Bedfordshire. For the trial and judicial murder of his son, the Hon. John Byng, see BRITAIN.

BYNKERSHOEK, CORNELIUS VAN, a distinguished Dutch jurist, was born at Middleburg in Zealand, in 1673. In the prosecution of his legal studies he found the common law of his country so defective, as to be nearly useless for practical purposes. This abuse he resolved to reform, and took as the basis of a new system the principles of the ancient Roman law. His works are very voluminous. Of these the most important are the *Observationes Juris Romani*, published in 1710, of which a continuation in four books appeared in 1733; his treatise *De Dominio Maris*, published in 1721; and his *Quæstiones Juris Publici*, published in 1737. Complete editions of his works were published after his death; one in folio at Geneva in 1761, and another in two volumes folio at Leyden in 1766.

BYROM, JOHN, an ingenious poet born at Kersall, near Manchester in 1691, and educated at Trinity College, Cambridge. His first poetical essay appeared in the Spectator, No. 603, beginning, "My time, O ye Muses, was happily spent;" which, with two humorous letters on dreams, are to be found in the eighth volume. He was elected a member of the Royal Society in 1723; and having originally entertained thoughts of practising physic, he used to be styled doctor by his friends, though he had never obtained a diploma. Having reduced himself to narrow circumstances by a precipitate marriage, he supported himself by teaching a new method of writing short-hand, of his own invention, until an estate devolved to him by the death of an elder brother. He was a man of lively wit; of which, whenever a favourable opportunity tempted him to indulge it, he gave many specimens. He died in 1763; and a collection of his miscellaneous poems was printed at Manchester, in two vols. 8vo, 1773, and reprinted at Leeds in 1814, with a Life of Byrom by an anonymous writer.

BYRON, LORD GEORGE GORDON, the only son of Captain Byron, and Catharine, sole child and heiress of George Gordon, Esq. of Gight, in Scotland, was born on the 22d January 1788, in Holles Street, London. His father, a man of dissolute and extravagant habits, died in 1791, at Valenciennes, leaving his widow, who was then residing at Aberdeen, to support herself and her son on a pittance of L.135 per annum. In 1794 his cousin, the grandson of the fifth Lord Byron, died in Corsica, and he became the presumptive heir to the peerage. The fifth Lord Byron died in 1798, and he succeeded to the title; and in the autumn of that year removed with his mother from Aberdeen to Newstead Abbey, in Nottinghamshire, which since the reign of Henry VIII. had been in the possession of the ancient family of Byron. Lord Byron had received the first rudiments of education at a grammar-school in Aberdeen. He was next sent in 1799 to the school of Dr Glennie at Dulwich, and in 1801 to Harrow, which he quitted in 1805. He is described by the head master of the latter school, the Rev. Dr Drury, as sensitive in disposition, intractable except by gentle means, shy, defectively educated, and ill prepared for a public school; but exhibiting the germs of considerable talent, though it does not appear to have been then foreseen in what mode his talents would display themselves. He excelled in declamation; and oratory, rather than poetry, was thought to be the prevailing bent of his genius. He seems to have been an active and spirited boy, at first unpopular, but finally a favourite; ardent in his school friendships, and jealous of the attachment of those whom he preferred. Among these the most learned were Lords Clare and Delawarr, the Duke of Dorset, Mr Harness, and Mr Wingfield. He was on friendly but less intimate terms with the most distinguished of his school-fellows, the late Sir Robert Peel. In classical scholarship Lord Byron acknowledged himself very inferior to Peel; but he was thought superior to him and to most others in general information. This was indeed extensive to a very unusual degree; and he has left on record an almost incredible list of works, in many various departments of literature, which he had read before the age of fifteen.

In October 1805 he was removed to Trinity College, Cambridge. He slighted the university, neglected its studies, and rebelled against its authority. Meanwhile he had commenced his poetical career, but at first feebly and with faint promise of future excellence. He first attempted poetry as early as 1800, under the inspiration of a boyish attachment to his young cousin, a daughter of Admiral Parker. In November 1806 he caused to be printed by Ridge, a bookseller at Norwich, for private circulation, a small volume of poems, among which one, written at the age of fifteen, is remarkable as containing a presage of his future fame. Some of the poems in this collection were of too licentious a character; and, on the advice of Mr Becker, a gentleman to whom the first copy had been presented, it was with praiseworthy promptitude suppressed, and replaced by a purified edition. In 1807 appeared his first published work, *The Hours of Idleness*; a collection of poems little worthy of his talent, and chiefly remembered through the castigation which it received from the *Edinburgh Review*. To this critique, which galled but did not depress him, we owe the first spirited outbreak of his talent, the satire entitled *English Bards and Scotch Reviewers*, which was published in March 1809. The length of this poem was increased, and many changes made in it, during its progress through the press. Censures of individuals were turned into praises, and praises into censures, with all the fickleness and precipitance of his age and character. It contained many harsh judgments, of which he afterwards repented; and able and vigorous as the satire was, and creditable to his talents, the time soon arrived when he was laudably anxious to suppress it. A few days previous to the publication of this

satire, on the 17th of March 1809, he took his seat in the House of Lords. He seems on that occasion to have keenly felt the loneliness of his position. He was almost unknown to society at large; there was no peer to introduce him; and his mortification led him to receive with ungracious coldness the welcome of the lord chancellor. His unfriended situation inspired him with disgust, and chilled his incipient longing for parliamentary distinction; and even a few days after taking his seat he retired to Newstead Abbey, and engaged with his friend Mr (now Sir J. C.) Hobhouse to travel together on the Continent. About the end of June the friends sailed together from Falmouth to Lisbon; travelled through part of Portugal and the south of Spain to Gibraltar; sailed thence to Malta and afterwards to Albania, in which country they landed on the 29th of September. From this time till the middle of the spring 1811, Lord Byron was engaged in visiting many parts of Greece, Turkey, and Asia Minor; staying long at Athens, Constantinople, and Smyrna. He touched again, on his return, at Malta, quitted it on the 2d of June, and early in July, after two years absence, landed in England. His affairs during this period had fallen into disorder, and it became advisable to sell either Rochdale or Newstead. The latter he was then most anxious to retain, and professed that it was his " only tie" to England, " and if he parted with that, he should remain abroad." In a letter to a friend, written during his homeward voyage, he thus expresses his melancholy sense of his condition: " Embarrassed in my private affairs, indifferent to public,—solitary without the wish to be social,—with a body a little enfeebled by a succession of fevers, but a spirit I trust yet unbroken,—I am returning home without a hope, and almost without a desire." This gloom was still deepened by numerous afflictions. His mother died on the 1st of August, without his having seen her again since his return to England; and he was deprived by death of five other relatives and friends between that and the end of August. " In the short space of one month," he says, " I have lost her who gave me being, and most of those who made that being tolerable." Amongst the latter were Wingfield, and Matthews, the brother of the author of the *Diary of an Invalid*. At this period of distress he was approaching unsuspectingly a remarkable epoch of his fame. He had composed while abroad two poems very different in character, and which he regarded with strangely misplaced feelings; the one called *Hints from Horace*, a weak imitation of his former satire; the other the first two cantos of *Childe Harold*. The former he intended to publish immediately; but the latter he thought of so disparagingly (owing probably to the injudicious comments of the single friend who had hitherto seen it), that it might probably have never become known to the public but for the wise advice of Mr Dallas. In compliance with the request of that gentleman, he withheld the *Hints from Horace*, which would have been injurious rather than beneficial to his fame, and allowed *Childe Harold* to be offered for publication. He received from his publisher, Mr Murray, L.600 for the copyright, which he gave to Mr Dallas. The publication was long delayed; for though placed in the publisher's hands in August, it did not appear till the beginning of March 1812. It, however, received during this interval considerable improvements; and the fears of the author were allayed by the approbation of Mr Gifford, the translator of Juvenal, and then editor of the *Quarterly Review*. The success of the poem exceeded even the anticipation of this able critic; and Lord Byron emerged at once from a state of loneliness and neglect, unusual for one in his sphere of life, to be the magnet and idol of society. As he tersely says in his memoranda, " I awoke one morning and found myself famous." A few days before the publication of *Childe Harold*, he attracted attention, but in a minor degree, by his first speech in the House of Lords on the subject of the house-breaking bill. He opposed it, and with ability; and his first oratorical effort was much commended by Sheridan, Sir F. Burdett, and Lords Grenville and Holland. He had prepared himself, by having committed the whole of this speech to writing. It was well received, and he was extremely gratified by its success. He might perhaps have been incited by the praises it received to seek political distinction; but the greater success which attended his poem turned his ambitious feelings into a different channel. He nevertheless spoke again about six weeks afterwards, on a motion of Lord Donoughmore, in favour of the claims of the Roman Catholics, but less successfully than before. Less clearness was displayed in the matter of his speech, and his delivery was considered as theatrical. In the autumn of this year he wrote an address at the request of the Drury-lane Committee, to be spoken at the re-opening of the theatre; and not long afterwards he became a member of that committee. The same autumn he engaged to sell Newstead for L.140,000, of which L.60,000 was to remain in mortgage on the estate for three years; but this purchase was never completed. In May 1813 appeared his *Giaour*, a wildly poetical fragment, of which the story was founded on an event that had occurred at Athens while he was there, and in which he was personally concerned. It was written rapidly, and with such additions during the course of printing as to be more than trebled in length, and swelled from about four hundred lines to upwards of fourteen hundred. On the 2d of June in this year he spoke for the last time in the House of Lords, on presenting a petition from Major Cartwright. He had now apparently ceased to regard parliamentary distinction as a primary object of ambition.

In his journal of November 1813 is the following entry: " I have declined presenting the debtors' petition, being sick of parliamentary mummeries. I have spoken thrice, but I doubt my ever becoming an orator; my first was liked, my second and third, I don't know whether they succeeded or not; I have never set to it *con amore*." In November he had finished the *Bride of Abydos* (written in a week), and it was published the following month. The *Corsair*, a poem of still higher merit and popularity, appeared in less than three months afterwards: it was written in the astonishingly short space of ten days. During the year 1813 he appears to have first entertained a serious intention of marriage, and became a suitor to Miss Millbanke, only daughter and heiress of Sir Ralph Millbanke. His first proposal was rejected; but the parties continued on the footing of friendship, and maintained a correspondence, of which, and of that lady, he thus speaks, and it may be presumed with the most perfect sincerity, in his private journal: " Yesterday a very pretty letter from Annabella, which I answered. What an odd situation and friendship is ours! without one spark of love on either side, and produced by circumstances which in general lead to coldness on one side, and aversion on the other. She is a very superior woman, and very little spoiled, which is strange in an heiress—a girl of twenty—a peeress that is to be in her own right—an only child, and a *savante*, who has always had her own way. She is a poetess, a mathematician, a metaphysician, and yet withal very kind, generous, and gentle, with very little pretension: any other head would be turned with half her acquisitions and a tenth of her advantages." In September 1814 he made a second proposal by letter, which was accepted; and on the 2d of January 1815 he was married to Miss Millbanke, at Seaham, the country seat of her father. The only is-

sue of this marriage, Augusta Ada, was born on the 10th of December of that year. We cannot lift the veil of their domestic life; we can only state the unfortunate results. On the 15th of January 1816, Lady Byron left London for Kirkby Mallory, the residence of her parents, whither Lord Byron was to follow her. She had, with the concurrence of some of Lord Byron's relatives, previously consulted Dr Baillie respecting the supposed insanity of her husband, and by the advice of that gentleman had written to him in a kind and soothing tone. Lady Byron's impressions of the insanity of Lord Byron were soon removed, but were followed by a resolution on her part to obtain a separation. Conformably with this resolution, Sir Ralph Millbanke wrote to Lord Byron on the 2d of February, proposing such a measure. This proposal Lord Byron at first rejected, but afterwards consented to sign a deed to that effect. Dr Lushington, the legal adviser of Lady Byron, has stated in a published letter, that *he* "considered reconciliation impossible." Of the circumstances which led to such an event, and on which Dr Lushington founded such an opinion, the public is at present uninformed. We are therefore, in absence of full and satisfactory evidence, bound to suspend our judgment on the merits of this melancholy case, and dismiss it with the foregoing statement of the leading facts. In the course of the spring he published the *Siege of Corinth* and *Parisina.* He also wrote two copies of verses, which appeared in the public papers, *Fare thee well*, and *A Sketch from Private Life;* of which his separation from his wife, and the instrumentality which he imputes to an humble individual in conducing to that separation, were the themes. This private circumstance had become the subject of general comment. The majority of those who filled the circles in which Lord Byron had lately lived declared against him, and society withdrew its countenance. Lord Byron, deeply stung by its verdict, hastily resolved to leave the country; and on the 25th of April 1816 he quitted England for the last time. His course was through Flanders and along the Rhine to Switzerland, where, at a villa called Deodati, in the neighbourhood of Geneva, he resided during the summer. From thence he made two excursions, one in the central part of Switzerland, in company with Mr Hobhouse, and another shorter excursion with a celebrated poetical compeer Mr Shelley, with whom he became acquainted soon after his arrival at Geneva. He remained in Switzerland till October, during which time he had composed some of his most powerful works; the third canto of *Childe Harold*, the *Prisoner of Chillon*, *Darkness*, the *Dream*, part of *Manfred*, and a few minor poems. In October he quitted Switzerland in company with Mr Hobhouse, and proceeded by Milan and Verona to Venice. Here he resided from the middle of November 1816 to the middle of April 1817. During this period his principal literary occupation was the completion of *Manfred*, of which he re-wrote the third act. He visited Rome for about a month in the spring, and then returned to Venice, at which city, or at La Mira, in its immediate vicinity, he resided almost uninterruptedly from this time till 1819. He wrote during this period the *Lament of Tasso*, *Beppo*, the fourth canto of *Childe Harold*, *Marino Faliero*, the *Foscari*, *Mazeppa*, and part of *Don Juan*. The licentious character of his life while at Venice corresponded but too well with the tone of that production. His able biographer and friend Mr Moore, after adverting to his *liaison* with a married Italian woman, says: "Highly censurable in point of morality and decorum as was his course of life while under the roof of Madame * * it was (with pain I am forced to confess) venial in comparison with the strange headlong career of license to which, when weaned from that connection, he so unrestrainedly, and, it may be added, defyingly, abandoned himself." This course of unbridled libertinism received its first check from the growth of attachment which, as it was still unhallowed, not even the good which it may seem to have done in the substitution of a purer sentiment, will enable us to regard with satisfaction. In April 1819 he first became acquainted with the Countess Guiccioli, the young and newly-married wife of an elderly Italian nobleman. A mutual attachment, which appears to have commenced on the part of the lady, soon arose between Lord Byron and the Countess Guiccioli. Their passion was augmented by occasional separation, the interest excited by her severe illness during one of their forced absences, and the imprudent complaisance of the husband in leaving them much in the society of each other. They long lived together in a half-permitted state of intimacy, the lady appearing with the consent of her husband to share his protection with that of Lord Byron. But this equivocal position soon terminated in the separation of the Count and Countess Guiccioli. The lady then went to reside with her father; and under his sanction, during the next three or four years, she and Lord Byron enjoyed the intimate possession of each other's society. In December 1819 Lord Byron quitted Venice for Ravenna, where he remained till the end of October 1821. During this period he wrote part of *Don Juan*, the *Prophecy of Dante*, *Sardanapalus*, a translation of the first canto of *Pulci's Morgante Maggiore*, and the mysteries, *Heaven and Earth*, and *Cain;* the latter of which may be justly considered as among the most faulty in principle, and powerful in execution, of the productions of his genius. He also wrote a letter on Mr Bowles's strictures on Pope, dated 7th February 1821, in which he defends the poet against his commentator; and an answer to an article in Blackwood's Magazine, entitled "Remarks on Don Juan," but this was never published.

During this period an insurrectionary spirit broke out in Italy; the Carbonari appeared; and secret societies began to be formed. The brother of the Countess Guiccioli, Count Pietro Gamba, espoused the cause of the insurgents, and through his means Lord Byron became implicated in the proceedings of that party. In his private journal of 16th February 1821, Lord Byron complains of the conduct of that gentleman and others, in sending to his house, without apprising him, arms with which he had a short time previously furnished them at their request, and thereby endangering his safety, and exposing him to the vengeance of the government, which had lately issued a severe ordinance against all persons having arms concealed. In July 1821, the father and brother of Madame Guiccioli were ordered to quit Ravenna, and repaired with that lady, first to Florence, and afterwards to Pisa, where they were joined in October by Lord Byron. He remained at Pisa till September 1822, Madame Guiccioli still living with him under the sanction of her father, who, in consequence of one of the conditions of her separation from her husband, was always to reside with her under the same roof. While here he lost his illegitimate daughter Allegra, and his friend Shelley, who was drowned in July 1822 in the Bay of Spezia. The body was burned, and Lord Byron assisted at this singular rite. His principal associates during this time had been the Gambas, Shelley, Captain Medwyn, and Mr Trelawney. He had also become associated with the brothers John and Leigh Hunt, in a periodical paper called the *Liberal;* a transaction certainly disinterested, inasmuch as it does not appear that he expected either profit or fame to accrue to himself from the undertaking; and he seems to have allowed his name to be connected with it from a desire to serve the Hunts, of whom Leigh Hunt, with his wife and family,

received an asylum in his house. An affray with a serjeant-major at Pisa rendered his residence in that city less agreeable; and his removal from it was at length determined by an order from the Tuscan government to the Gambas to quit the territory. Accordingly, in September 1822, he removed with them to Genoa. While at Pisa he had written, besides his contributions to the *Liberal*, *Werner*, the *Deformed Transformed*, and the remainder of *Don Juan*.

In April 1823 he commenced a correspondence with the Greek committee, through Messrs Blaquiere and Bowring, and began to interest himself warmly in the cause of the Greeks. In May he decided to go to Greece; and in July he sailed from Genoa in an English brig, taking with him Count Gamba, Mr Trelawney, Dr Burns, an Italian physician, and eight domestics; five horses, arms, ammunition, and medicine. The money which he had raised for this expedition was 50,000 crowns; 10,000 in specie, and the rest in bills of exchange. In August he arrived at Argostoli, the chief port of Cephalonia, in which island he established his residence till the end of December. His first feelings of exaggerated enthusiasm appear to have been soon cooled. Even as early as October he uses, in letters to Madame Guiccioli, such expressions as, "I was a fool to come here;" and, "of the Greeks I can't say much good hitherto; and I do not like to speak ill of them, though they do of one another." During the latter part of this year we find him endeavouring to compose the dissensions of the Greeks among themselves, and assisting them with a loan of L.4000. About the end of December 1823 he sailed from Argostoli in a Greek mistico, and after narrowly escaping capture by a Turkish frigate, landed on the 5th of January 1824 at Missolonghi. His reception here was enthusiastic. The whole population came out to welcome him; salutes were fired; and he was met and conducted into the town by Prince Mavrocordato, and all the troops and dignitaries of the place. But the disorganization which reigned in this town soon depressed his spirits, which had been raised by this reception, and filled his mind with reasonable misgivings of the success of the Greek cause. Nevertheless his resolution did not seem to fail, nor did he relax in his devotion to that cause, and in his efforts to advance it. About the end of January 1824 he received his commission from the Greek government as commander of the expedition against Lepanto, with full powers both civil and military. He was to be assisted by a military council, with Bozzari at its head. Great difficulties attended the arrangement of this expedition, arising principally from the dissensions and jealousies of the native leaders, and the mutinous spirit of the Suliote troops; with which latter, on the 14th of February, Lord Byron came to a rupture, in consequence of their demand, that about a third part of their number should be raised from common soldiers to the rank of officers. Lord Byron was firm, and they submitted on the following day. Difficulties in the civil department harassed him at the same time, aggravated by a difference of opinion between himself and Colonel Stanhope, on the subject of a free press, which the latter was anxious to introduce, and for which, on the other hand, Lord Byron considered that Greece was not yet ripe. On the 15th of February, the day of the professed submission of the Suliotes, he was seized with a convulsive fit, and for many days was seriously ill. While he was on a sick bed, the mutinous Suliotes burst into his room, demanding what they called their rights; and though his firmness then controlled them, it soon afterwards became necessary to get rid of these lawless soldiers, by the bribe of a month's pay in advance,—and with their dismissal vanished the hopes of the expedition against Lepanto. After this he turned his mind chiefly to the fortification of Missolonghi, the formation of a brigade, and the composition of the differences among the Greek chieftains. Since his attack in February he had never been entirely well. Early in April he caught a severe cold through exposure to rain. His fever increased, and in consequence of his prejudice against bleeding, that remedy was delayed till it was too late to be effectual. On the 17th (the second day after he had been bled) appearances of inflammation in the brain presented themselves. The following day he became insensible, and about twenty-four hours afterwards, at a quarter past six in the evening of the 19th of April 1824, Lord Byron breathed his last. Public honours were decreed to his memory by the authorities of Greece, where his loss was deeply lamented. The body was conveyed to England, and on the 16th of July was deposited in the family vault, in the parish church of Hucknell, near Newstead, in the county of Notts. By his will, dated 29th July 1815, Lord Byron bequeathed to his half-sister, Mrs Leigh, during her life, and after her death to her children, the monies arising from the sale of all such property, real and personal, as was not settled upon Lady Byron and his issue by her. The executors were Mr Hobhouse, and Mr Hanson, Lord Byron's solicitor.

The personal appearance of Lord Byron was prepossessing. His height was five feet eight and a half inches; his head small; his complexion pale; hair dark brown and curly; forehead high; features regular and good, and somewhat Grecian; eyes light grey, but capable of much expression. He was lame in the right foot, owing, it was said, to an accident at his birth; which circumstance seems always to have been to him a source of deep mortification, little warranted by its real importance. It did not prevent him from being active in his habits, and excelling in various manly exercises. He was a very good swimmer; successfully crossed the Hellespont in emulation of Leander; swam across the Tagus, a still greater feat; and, greatest of all, at Venice in 1818, from Lido to the opposite end of the grand canal, having been four hours and twenty minutes in the water without touching ground. In his younger days he was fond of sparring; and pistol-shooting, in which he excelled, was his favourite diversion while in Italy. In riding, for which he professed fondness, he did not equally excel. He was nervous both on horseback and in a carriage, though his conduct in Greece, and at other times, proved his unquestionable courage on great occasions. He had always a fondness for animals, and seemed to have preferred those which were of a ferocious kind. A bear, a wolf, and sundry bull-dogs, were at various times among his pets. The habits of his youth, after the period of boyhood, were not literary and intellectual; nor were his amusements of a refined or poetical character. He was always shy, and fond of solitude; but when in society, lively and animated, gentle, playful, and attractive in manner; and he possessed the power of quickly conciliating the friendship of those with whom he associated. He was very susceptible of attachment to women. The objects of his strongest passions appear to have been Miss Chaworth, afterwards Mrs Musters, and the Countess Guiccioli. His amours were numerous, and there was in his character a too evident proneness to libertinism. His constitution does not seem ever to have been strong, and his health was probably impaired by his modes of life. He was abstemious in eating, sometimes touching neither meat nor fish. Sometimes also he abstained entirely from wine or spirits, which at other times he drank to excess, seldom preserving a wholesome moderation and regularity of system. His temper was irascible, yet placable. He was quickly alive to tender and generous emotions, and performed many acts of disinterested liberality, even to-

wards those whom he could not esteem, and in spite of parsimonious feelings, which latterly gained hold upon him. He was a man of a morbid acuteness of feeling, arising partly from original temperament, and partly from circumstances and habits. He had been ill educated; he had been severely tried; his early attachments, and his first literary efforts, had equally been unfortunate; he had encountered the extremes of neglect and admiration; pecuniary distresses, domestic afflictions, and the unnerving tendency of dissipated habits, had all conspired to aggravate the waywardness of his excitable disposition. It is evident that, in spite of his assumed indifference, he was always keenly alive to the applause and censure of the world; and its capricious treatment of him more than ordinarily encouraged that vanity and egotism which were conspicuous traits of his character.

The religious opinions of Lord Byron appear, by his own account of them, to have been "unfixed;" but he expressly disclaimed being one of those infidels who deny the Scriptures, and wish to remain "in unbelief." In politics he was liberal, but his opinions were much influenced by his feelings; and, though professedly a lover of free institutions, he could not withhold his admiration even from tyranny when his imagination was wrought upon by its grandeur. He would not view Napoleon as the enslaver of France; he viewed him only as the most extraordinary being of his age, and he sincerely deplored his fall.

Lord Byron's prose compositions were so inconsiderable that they may almost be overlooked in the view of his literary character. His letters nevertheless must not pass wholly unnoticed. Careless as they are, and hastily written, they are among the most lively, spirited, and pointed specimens of epistolary writing in our language, and would alone suffice to indicate the possession of superior talent. The critical theories of Lord Byron were remarkably at variance with his practice. The most brilliant supporter of a new school of poetry, he was the professed admirer of a school that was superseded. The most powerful and original poet of the nineteenth century, he was a timid critic of the eighteenth. In theory he preferred polish to originality or vigour. He evidently thought Pope the first of our poets; he defended the unities; praised Shakspeare grudgingly; saw little merit in Spencer; preferred his own *Hints from Horace* to his *Childe Harold's Pilgrimage;* and assigned his eminent contemporaries Coleridge and Wordsworth a place far inferior to that which public opinion has more justly accorded to them.

The poetry of Lord Byron produced an immediate effect unparalleled in our literary annals. Of this influence much may be attributed, not only to the real power of his poetry, but also to the impressive identification of its principal characteristics with that which, whether truly or falsely, the world chose to regard as the character of the author. He seemed to have unbosomed himself to the public, and admitted them to view the full intensity of feelings which had never before been poured forth with such eloquent directness. His poems were as tales of the confessional, portraitures of real passion, not tamely feigned, but fresh and glowing from the breast of the writer. The emotions which he excelled in displaying were those of the most stormy character,—hate, scorn, rage, despair, indomitable pride, and the dark spirit of misanthropy. It was a narrow circle, but in that he stood without a rival.

His descriptive powers were eminently great. His works abound in splendid examples; among which the Venetian night-scene from Lioni's balcony, Terni, the Coliseum viewed by moonlight, and the shipwreck in Don Juan, will probably rise foremost in the memories of many readers. In description he was never too minute. He selected happily, and sketched freely, rapidly, and boldly. He seized the most salient images, and brought them directly and forcibly to the eye at once. There was, however, in his descriptive talent, the same absence of versatility and variety which characterized other departments of his genius. His writings do not reflect nature in all its infinite change of climate, scenery, and season. He portrayed with surpassing truth and force only such objects as were adapted to the sombre colouring of his pencil. The mountain, the cataract, the glacier, the ruin,—objects inspiring awe and melancholy,—seemed more congenial to his poetical disposition than those which led to joy or gratitude.

His genius was not dramatic; vigorously as he portrayed emotions, he was not successful in drawing characters; he was not master of variety; all his most prominent personages are strictly resolvable into one. There were diversities, but they were diversities of age, clime, and circumstances, not of character. They were merely such as would have appeared in the same individual when placed in different situations. Even the lively and the serious moods belonged alike to that one being; but there was a bitter recklessness in the mirth of his lively personages, which seems only the temporary relaxation of that proud misanthropic gloom that is exhibited in his serious heroes; and each might easily become the other. It may also be objected to many of his personages, that, if tried by the standard of nature, they were essentially false. They were sublime monstrosities;—strange combinations of virtue and vice, such as had never really existed. In his representations of corsairs and renegades, he exaggerates the good feelings which may, by a faint possibility, belong to such characters, and suppresses the brutality and faithlessness which would more probably be found in them, and from which it is not possible that they should have been wholly exempt. His plan was highly conducive to poetical effect; but its incorrectness must not be overlooked in an estimate of his delineation of human character. In his tragedies there is much vigour; but their finest passages are either soliloquies or descriptions, and their highest beauties are seldom strictly of a dramatic nature. Many of his dialogues are scarcely more than interrupted soliloquies; many of his arguments such as one mind would hold with itself. In fact, in his characters, there was seldom that degree of variety and contrast which is requisite for dramatic effect. The opposition was rather that of situation than of sentiment; and we feel that the interlocutors, if transposed, might still have uttered the same things.

It is to be deplored that scarcely any moral good is derivable from the splendid poetry of Lord Byron. The tendency of his works is to shake our confidence in virtue, and to diminish our abhorrence of vice;—to palliate crime, and to unsettle our notions of right and wrong. Even many of the virtuous sentiments which occur in his writings are assigned to characters so worthless, or placed in such close juxtaposition with vicious sentiments, as to induce a belief that there exists no real definable boundary; and it may perhaps be said with truth, that it would have been better for the cause of morality, if even those virtuous sentiments had been omitted. Our sympathy is frequently solicited in the behalf of crime. Alp, Conrad, Juan, Parisina, Hugo, Lara, and Manfred, may be cited as examples. They are all interesting and vicious. In the powerful drama of *Cain*, the heroes are Lucifer and the first murderer; and the former is depicted, not like the Satan of Milton, who believes and trembles, but as the compassionate friend of mankind. Resistance to the will of the Creator is represented as dignified and commendable; obedience and faith as mean, slavish, and con-

temptible. It is implied that it was unmerciful to have created us such as we are, and that we owe the Supreme Being neither gratitude nor duty. Such sentiments are clearly deducible from this drama. Whether they were those of Lord Byron is not certain; but he must be held accountable for their promulgation. (T. H. L.)

BYRON, *Hon. John*, the British admiral and circumnavigator, second son of the fourth Lord Byron, and grandfather of the poet, was born November 8th, 1723. He began his naval career in the eighth year of his age, and while still very young accompanied Anson in his voyage of discovery round the world. The dreadful hardships that he endured on this voyage he has recorded in his narrative. On his return home he was raised to the rank of commander, and soon after to that of post-captain. During many successive years he saw a great deal of hard service, and so constantly had he to contend on his various expeditions with adverse gales and dangerous storms, that he was aptly nicknamed by the sailors "Foul-weather Jack." It is to this that Lord Byron alludes in his famous *Epistle to Augusta*:—

> "A strange doom is thy father's son's, and past
> Recalling as it lies beyond redress,
> Reversed for him our grandsire's fate of yore,
> He had no rest at sea, nor I on shore.

In 1769 he was appointed governor of Newfoundland. In 1775 he attained his flag rank, and in the following year became a vice-admiral. In 1778 he was despatched with a fleet to watch the movements of the Count d'Estaing, who was setting out from France with an armament to assist the Americans. With this commander, in the July of the following year, he fought an indecisive engagement off Grenada. He shortly after returned to England, and retired into private life. He died on the 10th of April 1786.

BYSSUS, or BYSSUM, *in Antiquity*, a fine thready cloth produced in India, Egypt, and the vicinity of Elis, of which the richest apparel was made, especially that worn by the Jewish and Egyptian priests. Some interpreters render the Greek βύσσος, which occurs both in the Old and New Testament, by *fine linen*. But other versions, as Calvin's, and the Spanish one printed at Venice in 1556, explain the word by *silk*. M. Simon, who renders the word by fine linen, adds a note to explain it, bearing "that there was a fine kind of linen, very dear, which great lords alone wore in this country as well as in Egypt;" an account which agrees perfectly well with that given by Pliny and by Hesychius, as well as with the observation of Bochart, that the byssus was a finer kind of linen, which was frequently dyed of a crimson or purple colour. Some authors suppose byssus to have been cotton; some the *linum asbestinum;* while others conceive it to have been the bunch of silky hair found adhering to the pinna marina, by which the latter attaches itself to neighbouring bodies. There were two sorts of byssus; that of Elis, and that of Judæa, which was the finest. Bonfrerius remarks, that there must have been two sorts of byssus, one finer than ordinary, inasmuch as there are two Hebrew words used in Scripture to denote byssus; one of which is always used in speaking of the habit of the priests, and the other in alluding to that of the Levites. (See Yates, *Textrinum Antiquorum*, p. 267, &c.)

BYZANTINE HISTORIANS, a series of Greek writers who have given an account of the Eastern or Byzantine empire from the time of Constantine, A.D. 325, to the conquest of Constantinople by the Turks, A.D. 1453. They may be divided into four classes. 1st, Those whose works form a continuous history of the Byzantine empire during the above mentioned period. The works of these authors, who are nearly thirty in number, constitute the chief authority for the history of that eventful period. 2d, The chronographers, a very numerous class, who have given a brief chronological summary of universal history from the Creation down to their own times. 3d, The writers who have treated of particular portions of Byzantine history. 4th, Those who have written on the politics, statistics, manners, antiquities, &c., of the empire. A collection of the Byzantine writers was published at Paris by order of Louis XIV., in 36 vols. fol., 1645–1711. This edition was reprinted with additions at Venice, 1727–1733. Besides these, many of the Byzantine historians were published separately at different places. A new edition of the whole was commenced by Niebuhr, Bonn, 1828, 8vo, under the title of *Corpus Scriptorum Historiæ Byzantinæ, editio emendatior et copiosior*, of which many volumes have already appeared. This important work is still (1853) in course of publication.

BYZANTIUM, an ancient Greek city on the shores of the Bosporus, which occupied the most easterly of the seven hills on which the modern Constantinople has been built. It is said to have been founded by a band of Megarians B.C. 667, but the original settlement having been destroyed in the reign of Darius Hystaspes by the Satrap Otanes, it was recolonized by Pausanias, who wrested it from the hands of the Medes after the battle of Platæa—a circumstance which has led several ancient chroniclers to ascribe its foundation to him. The advantages of its situation as a place of commerce, which are said to have been pointed out to the Megarians by the oracle of Apollo—in the same way that its boundaries were afterwards revealed to Constantine by an invisible guide—quickly gave it pre-eminence over the other Dorian colonies on the coast. Its position on the Bosporus gave it complete control of the extensive corn-trade carried on by the merchants of the west with the northern shores of the Euxine, the absence of tides and the depth of its harbour rendered its quays accessible to vessels of large burden without the intervention of boats, while the pelamys and other fisheries at the mouth of the Lycus were so lucrative as to procure for the deeply curved bay into which that river fell the appellation of the Golden Horn. The greatest hindrance to its continued prosperity consisted in the miscellaneous character of the population, partly Lacedæmonians and partly Athenians, who flocked to it under Pausanias. From this circumstance it was the subject of dispute between both the states, and alternately in the possession of each, till it achieved its independence of both only to fall into the hands of the Macedonians; and from the same cause arose the violent contests of its intestine factions, which ended in the establishment of a rude and turbulent democracy. About seven years after its second colonization, Cimon wrested it from the hands of the Lacedæmonians; but it soon after revolted, and returned to its former allegiance. Alcibiades, after a severe blockade (B.C. 408) gained possession of the city through the treachery of the Athenian party; and it continued an ally of Athens until B.C. 405, when it was retaken by Lysander after the battle of Aigos-potamoi. It was under the Lacedæmonian power when the Ten Thousand were quartered in it after the retreat; when exasperated by the conduct of the governor, they mutinied and made themselves masters of the city, and would have pillaged it had they not been repressed by the firmness and promptitude of Xenophon. In B.C. 390 Thrasybulus, with the assistance of Heracleides and Archebius, succeeded in expelling the Lacedæmonian oligarchy, and in restoring the Athenian interest both in Byzantium and Chalcedon. By his influence also the government was changed into a democracy; and under the new constitution, as under the former oligarchy, the native Bithynians, into whose territories the colonists of Byzantium and Chalcedon had for half a century been making joint inroads, suffered the degradation and misery of Helots. After having withstood an attempt under Epaminondas to restore it to the Lacedæmonians, Byzantium joined with Rhodes, Chios, Cos, and Mausolus King of Caria, in throwing off the Athenian yoke, but soon returned to its allegiance when besieged by Philip of Macedon, after he had overrun Thrace. The succours which were sent by

Byzantium. the Athenians under Chares, on their arrival suffered a severe defeat from Amyntas, the Macedonian admiral; but in the following year they gained a decisive victory under Phocion, and compelled Philip to raise the siege. The wonderful deliverance of the besieged from a surprise, by means of a flash of light which illuminated the northern horizon and revealed the advancing masses of the Macedonian army, has rendered this siege peculiarly memorable. As a memorial of the miraculous interference the Byzantines erected an altar to Torch-bearing Hecate, and stamped a crescent on their coins as a symbol of the portent, a device which is retained by the Turks to this day. In gratitude for the Athenian succours, procured chiefly by the eloquence of Demosthenes, they granted the Athenians the right of isopolity, coupled with extraordinary privileges, and erected a monument in honour of the event in a public part of the city. During the reign of Alexander, Byzantium was compelled to acknowledge the Macedonian supremacy; and after the decay of the Macedonian power, although it regained its independence, it suffered from the repeated incursions of the Scythian hordes which overran the unprotected province. The losses which they sustained by land roused the Byzantines to indemnify themselves on the vessels which still crowded the harbour, and the fleets of merchantmen which cleared the straits; but this had the effect of provoking a war with the neighbouring naval powers. The exchequer being drained by the payment of 10,000 pieces of gold to buy off the Gauls who had invaded their territories about the year 279 B.C., and the subsequent imposition of an annual tribute which was ultimately raised to 80 talents, they were compelled to exact a toll on all the ships which passed the Bosporus; a measure which the Rhodians resented and avenged by a war, in which, though supported by Attalus King of Pergamus, they were defeated, and obliged to sue for peace on very disadvantageous terms. The subsequent retreat of the Gauls to Asia gave Byzantium another opportunity of regaining its independence, and enabled it to render considerable services to Rome in the contests with Philip II. of Macedon, Antiochus, and Mithridates. During the first years of its alliance with Rome it held the rank of a free and confederate city; but having sought the arbitration of the capital on some of its domestic disputes, it was subjected to the imperial jurisdiction, and gradually stripped of its privileges, until reduced to the status of an ordinary Roman colony. In recollection of its former services, the Emperor Claudius remitted the heavy tribute which had been imposed on it; but the last remnant of its independence was taken away by Vespasian, who, in answer to a remonstrance from Apollonius of Tyana, taunted the inhabitants with having "forgotten to be free." During the civil wars, it espoused the party of Pescennius Niger; and though skilfully defended by the engineer Periscus, it was besieged and taken (A.D. 196) by Severus, who destroyed the city, demolished the famous wall built of massive stones so closely riveted together as to appear one block, put the principal inhabitants to the sword, and subjected the remainder to the Perinthians. Severus, however, afterwards relented, and rebuilding a large portion of the town, gave it the name of Augusta Antonina. He ornamented the city with baths, and surrounded the hippodrome with porticoes; but it was not till the time of Caracalla that it was restored to its former political privileges. It had scarcely begun to recover its former flourishing position when, from the capricious resentment of Gallienus, the inhabitants were once more put to the sword, and the town given up to be pillaged. From this disaster the inhabitants recovered so far as to be able to give an effectual check to an invasion of the Goths in the reign of Claudius II., and its fortifications were greatly strengthened during the civil wars which followed the abdication of Diocletian. Licinius, after his defeat before Adrianople, retired to Byzantium, where he was besieged by Constantine, and compelled to surrender. To check the inroads of the barbarians on the north of the Black Sea, Diocletian had resolved to transfer his capital to Nicomedia; but Constantine, struck with the advantages which the situation of Byzantium presented, resolved to build a new city there on the site of the old, and transfer the seat of government to it. The design was quickly put into execution, and the new capital was inaugurated with special ceremonies, A.D. 330. See CONSTANTINOPLE.

The ancient historians invariably note the profligacy of the inhabitants of Byzantium. They are described as an idle and depraved people, spending their time for the most part in loitering about the harbour, or carousing over the fine wine of Maronea and the neighbourhood. In war they trembled at the sound of a trumpet, in peace they quaked before the shouting of their own demagogues; and during the assault of Philip II. they could only be prevailed on to man the walls by the savour of the extempore cook-shops distributed along the ramparts.

Bzovius. BZOVIUS or BZOWSKI, ABRAHAM, one of the most voluminous writers of the seventeenth century, was born at Prosovitz in 1567. Losing his parents in early life, he was brought up by his grandmother, who sent him to study at Cracow, where he entered the order of Dominicans. From Cracow he went to Milan, where he taught philosophy, and afterwards to Bologna, where he read lectures on theological subjects. He soon afterwards returned to Poland, and was appointed principal of a Dominican college. A mandate of the pope, Paul V., summoned him to Rome, where he found apartments prepared for him in the Vatican, and the office of librarian of the *Virginio dei Ursini* at his disposal. While living in the papal palace, he was robbed, and his attendant murdered; and he soon after retired to the convent of Minerva, and there devoted himself entirely to literature for the remainder of his days. His death took place in 1637. Though he wrote an astonishing number of books, he is now chiefly remembered for his continuation of the Annals of Baronius. This work he took up from the year 1198—where Baronius left off. Nine volumes of it have been published; the first eight of which appeared at Cologne, 1616–1641, the last at Rome in 1672.

C.

C, THE third letter and second consonant of the alphabet, is pronounced like *k* before the vowels *a*, *o*, and *u*, and like *s* before *e*, *i*, and *y*. C is formed, according to Scaliger, from the κ of the Greeks, by retrenching the stem or upright line; though others derive it from the כ of the Hebrews, which has in effect the same form; only, that as the Hebrews read towards the left, and the Latins and other western nations towards the right, each turned the letter their own way. However, the C not being the same as to sound with the Hebrew *caph*, כ, and it being certain that the Romans did not borrow their letters immediately from the Hebrews or other orientals, but from the Greeks, the derivation from the Greek κ is upon the whole the more probable. Indeed Montfaucon, in his *Palæographia*, gives some forms of the Greek κ which approach very near to that of our C; and Suidas calls the C the Roman *kappa*. Before the first Punic war C held the place which is now occupied by G, as appears from the Duilian Column, where we meet with *acnam* for *agnam*, *lecionem* for *legionem*, and *exfociont* for *effugiunt*. The second sound of C resembles that of the Greek Σ; and many instances occur of ancient inscriptions in which Σ has the same form with our C. Grammarians are pretty generally agreed that the Romans pronounced their Q like our C, and their C like our K. Mabillon informs us that Charles the Great was the first who wrote his name with a C; whereas all his predecessors of the same name wrote it with a K; and the same difference is observable in their coins. As an abbreviature, C stands for Caius, Carolus, Cæsar, *condemno*, &c., and CC represent *consulibus*. As a numeral, C signifies 100, CC 200, and so on. C, in *Music*, placed after the cleff, intimates that the music is in common time, which is either quick or slow as it is joined with allegro or adagio; but if alone, it is usually adagio. If the C be crossed or turned, the first requires the air to be played quick, and the last very quick.

CAABA, or KAABA, properly signifies a square stone building, but is particularly applied to the temple of Mekka, built, as the Mahommedans pretend, by Abraham and his son Ishmael. This temple enjoys the privilege of an asylum for all sorts of criminals; but it is most remarkable for the pilgrimages made to it by the devout Moslemins, who pay it so great a veneration that they account the mere sight of its sacred walls, without any particular act of devotion, as meritorious in the sight of God as the most careful discharge of their duty for the space of a whole year in any other temple. See MEKKA.

CAB, a Hebrew measure, mentioned in 2 Kings vi. 25. The Rabbins make it the sixth part of a *seah* or *satum*, and the eighteenth part of an ephah. A cab would hence contain $3\frac{1}{3}$ pints of our wine measure, or $2\frac{5}{6}$ pints of our old corn measure.

CABAL (Italian *cabala*, knowledge of secret things; Spanish *cabala*, secret science), a number of persons united in some close design, usually for the purpose of promoting their private views by intrigue.

This name was given to one ministry of Charles II., consisting of Clifford, Ashley, Buckingham, Arlington, and Lauderdale, the initials of whose names compose the word cabal.

CABALLARIA, in middle-age writers, lands held by the tenure of furnishing a horseman with suitable equipage during war, or when the lord had occasion for him.

CABALLINE, pertaining to a horse; as *caballine aloes*, so called from being chiefly used as a purge for horses.

CABANIS, PIERRE JEAN GEORGE, a distinguished writer and physician at Paris, was born at Conac in 1757. His father, Jean Baptiste Cabanis, was a lawyer of eminence, and chief magistrate of a district in the Lower Limousin, highly respected for his great acquirements and integrity, and entitled to the gratitude of his country for the many improvements he has introduced in agriculture and farming. Young Cabanis was sent at ten years of age to the college of Brives; and he afterwards studied at Paris, where he devoted himself to the acquisition of classical knowledge. At first he paid no attention to the lectures of his professors; but afterwards, of his own accord, he resumed those branches of his education in which he had remained deficient, and devoted himself entirely to the cultivation of his mind.

Thus constantly occupied, two years had passed away, when he received the offer of the place of secretary to a Polish nobleman. This offer he embraced without hesitation, and, though only sixteen, committed himself into the hands of strangers, in a distant country, which was represented to him as in a state of barbarism. This was in 1773, the year during which that diet was sitting which was to deliberate upon giving its sanction to the first partition of Poland. The corrupt intrigues and compulsory measures which were practised on that occasion, inspired him with a contempt for mankind, and a degree of misanthropic gloom, which are generally the fruits of a later experience of human depravity. He returned to Paris two years afterwards, when Turgot, the friend of his father, was minister of finance. On being presented to this statesman he was received with kindness, and would soon have been placed in a situation perfectly conformable to his tastes and wishes, had not a court intrigue caused the sudden downfall of the minister.

He now felt the necessity of making up for the time he had lost, and again applied to his studies with his former ardour. He had contracted a friendship with the poet Roucher, who enjoyed some celebrity. This connection rekindled his taste for poetry; and the French Academy having proposed as a prize subject the translation of a passage in the *Iliad*, he not only ventured to appear as a competitor, but set about translating the entire poem. The two specimens which he sent to the Academy did not obtain any public notice, but they were judged of favourably by several persons of taste. He was soon, however, sensible of the emptiness of these applauses; and, urged by his father to choose a useful profession, he at length decided for that of medicine. Dubreuil offered to be his guide in the new and arduous career which he was commencing; and Cabanis continued for six years the pupil of this able master. In 1789 he published *Observations sur les Hôpitaux*, a work which procured him the appointment of administrator of hospitals at Paris.

His state of health requiring occasional relaxation, he fixed upon Auteuil, in the immediate vicinity of Paris, as his place of residence. He continued his intercourse with Turgot; was on terms of intimacy with Condillac, Thomas, and D'Alembert; and acquired the friendship of Holbach, Franklin, and Jefferson. During the last visit which Voltaire made to Paris, Cabanis was presented to him by Turgot, and read to him part of his translation of the *Iliad*, which that acute critic, though old, infirm, and fatigued with his journey, listened to with great interest, and bestowed much commendation on the talents of the author. Cabanis had now, however, long ceased to occupy himself with that work; and, even bade a formal adieu to poetry in his *Serment d'un Médecin*, which appeared in 1789. In the political struggle which now began to engross the general attention, Cabanis espoused with enthusiasm the cause of the revolution, to which he was attached from principle, and

Cabanis.

of which the opening prospects were thoroughly congenial to his active and ardent mind.

During the two last years of Mirabeau's life he was intimately connected with that extraordinary man, who had the singular art of pressing into his service the pens of all his literary friends. Cabanis united himself with this disinterested association of labourers, and contributed the *Travail sur l'Education Publique;* a tract which was found among the papers of Mirabeau at his death, and was edited by the real author soon afterwards in 1791. During the illness which terminated his life, Mirabeau confided himself entirely to the professional skill of Cabanis. Of the progress of the malady, and the circumstances attending the death of Mirabeau, Cabanis has drawn up a very detailed narrative, which is not calculated, however, to impress us with any high idea of his skill in the treatment of an acute inflammatory disease.

Condorcet was another distinguished character with whom Cabanis was intimate, and whom he endeavoured, though without success, to save from the destiny in which he afterwards became involved by the calamitous events of the revolution. Shortly after this he married Charlotte Grouchy, sister to Madame Condorcet and to General Grouchy; a union which was a great source of happiness to him during the remainder of his life.

After the subversion of the government of the terrorists, Cabanis, on the establishment of central schools, was named professor of *Hygiène* in the medical schools of the metropolis. Next year he was chosen member of the National Institute, and was subsequently appointed clinical professor. He was afterwards member of the Council of Five Hundred, and then of the Conservative Senate. The dissolution of the Directory was the result of a motion which he made to that effect. But his political career was not of long continuance. A foe to tyranny in every shape, he was decidedly hostile to the policy of Bonaparte, and constantly rejected every solicitation to accept a place under his government.

For some years before his death, his health became gradually more impaired, and he retired from the laborious duties of his profession, spending the greatest part of his time at the chateau of his father-in-law at Meulan. Here he solaced himself with reading his favourite poets, and even had it in contemplation to resume that translation of the *Iliad* which had been the first effort of his youthful muse. The rest of his time was devoted to kindness and beneficence, especially towards the poor, who flocked from all parts to consult him on their complaints. Cabanis died May 5, 1808, leaving a widow and a daughter.

Besides the tracts already mentioned, Cabanis was author of *Mélanges de Littérature Allemande, ou Choix de Traductions de l'Allemande,* &c., Paris, 8vo, 1797; *Du Degré de Certitude de la Médecine,* 1797 and 1803, containing a republication of his *Observations sur les Hôpitaux,* and his *Journal de la Maladie et de la Mort de Mirabeau l'ainé;* together with a short tract on the punishment of the guillotine, in which he combats the opinion of Soemmerring, Œlsuer, and Sue, that sensibility remains for some time after decapitation. This tract had already appeared in the *Magazin Encyclopédique,* and in the first volume of the *Mémoires de la Société Médicale d'Emulation.* This new edition also contains his *Rapport fait au Conseil des Cinq-cents sur l'Organisation des Ecoles de Médecine;* and a long dissertation entitled *Quelques Principes et quelques Vues sur les Secours Publiques. Quelques Considérations sur l'Organisation sociale en général, et particulièrement sur la nouvelle Constitution,* 12mo, 1799. His principal work, however, is that entitled *Des Rapports du Physique et du Morale de l'Homme,* 1803, in two volumes 8vo. This work was reprinted in the following year, with the addition of a copious analytical table of its contents by M. Destutt-Tracy, and alphabetical indexes by M. Sue. His *Coup d'Œil sur les Révolutions et les Réformes de la Médecine* appeared in 1803. Of this work we possess an excellent English translation, with notes by Dr Henderson. His only practical work on medicine is the *Observations sur les Affections Catarrhales en général, et particulièrement sur celles connues sous le nom de Rhumes de Cerveau, et Rhumes de Poitrine,* 8vo, 1807. He also wrote many interesting articles in the *Magazin Encyclopédique.*

Cabbage || Cabenda.

CABBAGE. See Horticulture.

CABBALA, or Kabbalah according to the Hebrew style, has a very distinct signification from that in which we understand it in our language. The word is an abstract, and means *reception,* a doctrine received by oral transmission. The rabbis who are called cabbalists study principally the combination of particular words, letters, and numbers, by which means they pretend to discover what is to come, and to see clearly into the sense of many difficult passages of Scripture. There are no sure principles of this knowledge, which in fact depends upon some particular traditions of the ancients; for which reason it is termed *cabbala.* The cabbalists have abundance of names which they call *sacred,* and not only make use of in invoking spirits, but imagine that they derive great light from them. They tell us that the secrets of the cabbala were discovered to Moses on Mount Sinai; and that these have been delivered down to them from father to son without interruption, and without any use of letters; for to write them down is what they are by no means permitted to do. This is likewise termed the oral law, as passing from father to son, in order to distinguish it from the written law. There is another cabbala, called *artificial,* which consists in searching for abstruse and mysterious significations of a word in Scripture, from which are borrowed certain explanations, by combining the letters which compose it. This cabbala is divided into three species, viz., the Gematria, the Notaricon, and the Temurah. The first, or Gematric, consists in, taking the letters of a Hebrew word for ciphers or arithmetical numbers, and explaining every word by the arithmetical value of the letters of which it is composed; the second, called Notaricon, consists in taking every particular letter of a word for an entire diction; and the third, called Temurah, or change, consists in making different transpositions or changes of letters, placing one for the other, or one before the other. Among the Christians, likewise, a certain sort of magic is, by mistake, called *cabbala,* and consists in using improperly certain passages of Scripture for magical operations, or in forming magical characters or figures with stars and talismans. Some visionaries among the Jews believe that our Saviour wrought his miracles by virtue of the ridiculous mysteries of the cabbala.

Wolfius has given an extended account of the cabbala, and of the numerous manuscripts and printed Jewish works in which its principles are contained, as well as abundant references to Christian authors who have treated of it. (*Biblioth. Hebr.* ii. 1191, *sq*) See also Beer, *Geschichte der Lehren aller Secten der Juden, und der Cabbala,* Brünn, 1822, 2 vols. 8vo.

CABBALISTS, or Kabbalists, the Jewish doctors who profess the study of the cabbala. In the opinion of these men, there is not a word, letter, nor accent in the law, without some mystery in it. The Jews are divided into two general sects; the Karaites, who refuse to receive either tradition or the Talmud, or anything but the pure texts of Scripture; and the Rabbinists, or Talmudists, who besides this receive the traditions of the ancients, and follow the Talmud. The latter are again divided into two other sects; pure rabbinists, who explain the Scripture in its natural sense, by grammar, history, and tradition; and cabbalists, who, to discover hidden and mystical senses, which they suppose to have been couched therein by God, make use of the cabbala and the mystical methods above mentioned.

CABENDA, a seaport town of Western Africa, in Lower Guinea, 40 miles north of the mouth of the Zaire, Lat. 5. 33. S. Long. 15. 40. E. From the great beauty of its situation, and the fertility of the adjacent country, it has been called the paradise of the coast. The harbour is well sheltered and commodious, and the trade is considerable.

CABEZA DEL BUEY, a town of Spain, province of Badajos, 86 miles E.S.E. from the city of that name. It contains 850 houses, 4 schools, and several manufactories of coarse frieze, linen, and cloth. Pop. 5395.

CABIN, an apartment in a ship for officers and passengers. There are many of these in a large ship, the principal of which is occupied by the captain. In small vessels there is one cabin in the stern, for the accommodation of the officers and passengers. The sleeping apartments in ships are also called cabins.

CABINET, a closet, small room, or retired apartment.

It is also the name of a piece of furniture, consisting of a chest with drawers and doors.

Cabinet, a word of daily use in modern politics, applies specifically to those heads of ministerial departments in Britain whose co-operative action marks the policy of the administration. It has a similar meaning in the United States, and is applied by analogy to the chief organs or advisers of the government in other countries. The word was first used in France, where it meant the inner apartment of a house, and when employed as a general term, that of the palace. To have the entrée of the cabinet meant to have influence with the sovereign, and at an early period the term was thus applied to the secret council of the king. It is singular that a body so great in its power and influence, and so well suited, according to all practice and experience, for conducting the business of a great constitutional state, should have arisen as it were by stealth, should possess no settled constitutional rights and functions, and should be subject to no specific responsibilities. By the older constitutional authorities it has always been held, that those sworn advisers of the monarch who form his privy-council are the responsible officers for conducting the government. A habit of listening to one or two favourite advisers, instead of laying matters before the privy-council, was frequently referred to as one of the innovations made by Charles I. in the direction of arbitrary government. The practice of consulting only a small committee was in full force in the reign of Charles II., whose cabinet at one time received the name of the "Cabal," from the initial letters of the names of its members. The practice became even more systematic after the Revolution, and was the object of an interesting debate in the year 1692, on the occasion of the king seeking the advice of the House of Commons on the crisis in the foreign relations of the nation. Mr Goodwin Wharton, referring to the divided and imperfect responsibility of the existing system, said, "The method is this:—Things are concerted in the cabinet and then brought to the council; such a thing resolved in the council and brought and put upon them for their assent without showing any reason. This has not been the method of England. I am credibly informed that it has been complained of in council, and not much backed there. If this method be, you will never know who gives advice." On the same occasion it was said by Mr Waller, "'cabinet council' is not a word to be found in our law books. We knew it not before; we took it for a nickname. Nothing can fall out more unhappily than to have a distinction made of the 'cabinet' and 'privy-council.' It has this effect in the country, and must have, that the justices of peace and deputy lieutenants will be afraid to act; they will say they cannot go on—and why? Because several of them have been misrepresented and are not willing to act; they know not who will stand by them, and are loth to make discoveries unless seconded. If some of the privy-council must be trusted and some not, to whom must any gentleman apply? Must he ask who is a cabinet-councillor? This creates mistrust in the people. I am sure these distinctions of some being more trusted than others have given great dissatisfaction."—(*Parl. Hist.*, v. 731–3.)

The continued prevalence of such views is apparent in the clause of the Act of Settlement of 1705, requiring all acts of state to be transacted in the privy-council, and signed by the members; a provision which, probably as inconsistent with a settled practice, was repealed two years afterwards. The last time when a privy-councillor entered a cabinet-council without invitation, was that memorable occasion of the last illness of Queen Anne, when the Dukes of Somerset and Argyle, believing that there was a plot to defeat the Hanover succession, entered the council-room and dictated measures for the safety of the kingdom and the proclamation of King George. The privy-council, from whom the cabinet is selected, now forms a considerable body, many of whom hold the membership as a mere mark of distinction. It has often been asked how the system of governing by a cabinet is consistent with personal responsibility, since there is no such executive body known to the law, it passes no specific acts, and the votes and opinions of its individual members are unrecorded. From this last feature, however, there seems to arise an effective collective responsibility, since every member of the cabinet is held to support and be compromised by the leading acts of the government. Certain great officers of state are invariably members of the cabinet; as the first lord of the treasury, the lord chancellor, the three principal secretaries of state, and the chancellor of the exchequer. Sometimes the post-master-general, the commander-in-chief, the chief secretary for Ireland, the president of the board of trade, and on one or two occasions the chief justice of the Queen's Bench, have been members. At the commencement of the year 1854, besides the invariable members, the cabinet included the lord president of the council, the lord privy-seal, the first lord of the admiralty, the president of the board of control, the secretary-at-war, and the first commissioner of public-buildings, while Lord Lansdowne and Lord John Russell were members without office. (J. H. B.)

CABIRI (Κάβειροι), mystic deities of antiquity whose names and rites were widely diffused, but whose special functions have not been determined. Even among the ancients themselves great diversity of opinion prevailed on this point. They are first mentioned as inhabiting the island of Lemnos, where they presided over the fruits of the earth, and vineyards in particular. Herodotus mentions that they were worshipped at Memphis in Egypt as the children of Vulcan; Stesimbrotus endeavours to identify them with the Corybantes and Curetes. Though the worship of these divinities spread gradually over the whole of Greece and Italy, it was nowhere performed with greater solemnity than in Lemnos, Imbros, and Samothrace. The mystic rites which accompanied the worship of these great and powerful deities, as celebrated in those islands, were only inferior in solemnity to the Eleusinian mysteries of the goddess Demeter (Ceres).

CABIRIA (Καβείρια), festivals in honour of the Cabiri, celebrated in Thebes and Lemnos, but especially in Samothracia, an island consecrated to the Cabiri. All persons initiated in the mysteries of these gods were thought to be thereby secure against storms at sea, and all other dangers. The ceremony of initiation was performed by placing the candidate, crowned with olive branches, and girded about the loins with a purple riband, on a kind of throne, about which danced the priests and persons previously initiated. (See Guthberlet, *De Mysteriis Deorum Cabirorum*; E. G. Haupt, *De Religione Cabiriaca*.)

CABLE, a large strong rope, or iron chain, made fast to the anchor, by which a ship is secured. It is usually 120 fathoms; hence the expression *a cable's length*. See Rope-making.

The *Sheet Anchor Cable* is the greatest cable belonging to a ship.

The *Stream Cable* is a hawser or rope used to moor the ship in a river or haven sheltered from the wind and sea.

Cabot.

CABOT, Sebastian, the celebrated navigator, and re-discoverer[1] of the American continent, was the son of John Cabot, a Venetian merchant resident in England, and was born about the year 1477. Although long the subject of much dispute, it is now certain that England was the place of his nativity. In an ancient collection of voyages and travels by Richard Eden, a learned writer and contemporary of Sebastian, the author in a marginal note says, "Sebastian Cabote tould me, that he was borne in Brystowe (Bristol), and that at iiii yeare ould he was carried with his father to Venice, and so returned agayne into England with his father after certayne years, whereby he was thought to have been born in Venice." (*Decades of the New World*, fol. 255.) It also appears that he returned, while still young (*pæne infans*), to England, and remained there till he grew up to manhood.

The brilliant discoveries of Columbus having awakened a spirit of enterprise throughout the enlightened nations of Europe, Henry VII. of England was not slow in perceiving the advantages to be gained by promoting adventure in the new career opened up to human ambition. The all-important and engrossing object was to discover a route to India; and an expedition in a north-westerly direction, ostensibly to reach what was called Cathay, or the Land of Spice, was projected by Sebastian Cabot, and fitted out under the auspices of the English government. The first patent, which bears date March 5, 1496 (Rymer, *Fœdera*, vol. xii. p. 595), was given to John Cabot and his three sons, Lewis, Sebastian, and Saucius. The patentees were empowered to set up the royal banner, and occupy and possess all the "newly found" lands in the name of the king, who reserved a fifth of the profits. It was also stipulated that the vessels should return to Bristol, and that the privilege of exclusive resort and traffic should belong to the patentees.

Although the patent was conferred on John Cabot and his three sons, there can be no doubt, even if the father did accompany the expedition, that its success was entirely owing to the genius of Sebastian.

It is now undoubted, that to Sebastian alone belongs the glory of the re-discovery of the *terra firma* of the Western World. The expedition, consisting of the ship commanded by Sebastian, and three or four smaller vessels, sailed from Bristol in the beginning of May 1497; and an ancient Bristol manuscript records the fact, that, "in the year 1497, the 24th June, on St John's day, was Newfoundland found, by Bristol men, in a ship called the Mathew." On the authority of Peter Martyr, we learn, that after quitting the north, where he reached latitude sixty-seven and a half, Cabot proceeded along the coast of the continent, to a latitude corresponding probably with that of the Straits of Gibraltar. Indeed he is said to have gone so far southward, "ut Cubam Insulam a læva longitudine graduum pene parem habuerit." A failure of provisions at this point compelled him to desist from further pursuit, and the expedition returned to England.

The second patent is dated 3d February 1498, and gives authority to "John Kabotto or his deputies," to take at pleasure six English ships, and "them convey and lede to the londe and isles of late found." Shortly after the date of this patent John Cabot died; and it is said that his sons Lewis and Saucius went to settle in Italy. Sebastian, however, did not abandon the enterprise in which he had embarked; and a second voyage was zealously undertaken under his superintendence. A ship equipped at the king's expense, along with four small vessels, sailed from Bristol in the spring of the year 1498. The result of the expedition is unfortunately wrapt in much obscurity. Gomara alone furnishes us with what may be a correct account. According to this author, Cabot "directed his course by the tracte of islande, uppon the Cape of Labrador, at lviii. degrees; affirmynge that, in the monethe of July, there was such could, and heapes of ise, that he durst passe no further; also, that the dayes were very longe, and in maner without nyght, and the nyghtes very clear. Certayne it is, that at the lx. degrees, the longest day is of xviii. houres. But consyderynge the coulde, and the straungeness of the unknowen lande, he turned his course from thense to the west, folowynge the coast of the lande of Baccalaos unto the xxxviii. degrees, from whense he returned to Englande." (Eden's *Decades*, fol. 318).

Cabot.

The results of this second voyage were not sufficiently important to induce Henry to equip another expedition. We have good authority for believing, however, that Cabot, in 1499, "with no extraordinary preparations sett forth from Bristoll, and made greate discoveries." (Seyer's *Memoirs of Bristol.*) But the narrative of Cabot's life for the fifteen years subsequent to the departure of his second expedition is meagre and unsatisfactory. One circumstance deserves notice, that during that period Amerigo Vespucci, in company with Hojeda, crossed the Atlantic for the *first time*, whilst Sebastian was prosecuting his third voyage.

After the death of Henry VII., upon the invitation of Ferdinand, Sebastian Cabot went to Spain; and Vespucci, who held the office of pilot-major, having died, he was appointed his successor. He was soon employed in a general revision of maps and charts; and his public and private character endeared him to most of the learned and good men in Spain. The death of Ferdinand put an end to an expedition then in contemplation. The ignoble commencement of the reign of Charles V. frustrated all further hopes of its prosecution; and Cabot returned to England, where, under Henry VIII. he got honourable employment, and performed another westwardly voyage in 1517, which, however, proved unsuccessful.

In 1518 we find Cabot in Spain, and again reinstated in the appointment of pilot-major. The dispute between Spain and Portugal in regard to their respective rights to the Moluccas having been decided at the congress of Badajos in 1524 in favour of Spain, a company was formed at Seville to open a commercial intercourse with those islands; and Cabot, with the title of Captain-general, after many delays, set sail with a fleet in April 1526. The squadron was ill assorted, and a mutiny broke out; in consequence of which he diverted his course from the Moluccas to the mouth of the Rio de la Plata, up which he penetrated about three hundred and fifty leagues. He erected a fort at St Salvador; and afterwards sailing up the Parana, he built other two forts. He subsequently entered the Paraguay, where he was drawn into a sanguinary contest with the natives. From the report then made by him to Charles V. it is probable, had he been supplied with means and ammunition, he would have made the conquest of Peru, which Pizarro afterwards accomplished with his own private resources. After tarrying in the hopes of receiving supplies, Cabot was forced to return to Spain, where he resumed his functions of pilot-major.

He finally settled in England, where he appears to have exercised a general supervision over the maritime concerns of the country, and enjoyed a pension of two hundred and fifty merks. It was then that he disclosed to Edward VI. his discovery of the phenomenon of the variation of the needle;—a discovery for which alone his name deserves to be immortalized. It was also at his instigation that the important expedition was undertaken which resulted in the opening of the trade with Russia; and in the charter of the company of merchant adventurers he was nominated governor for life, as "the chiefest setter forth" of the enterprise. Cabot lived to a very advanced age, and died about 1557,

[1] The continent of North America had been seen, and even repeatedly visited about five centuries before by the Icelanders.

probably in London; but neither the date of his death nor the place of his interment is properly authenticated.

Sebastian Cabot may be justly regarded as one of the most illustrious navigators the world has ever seen; and England owes him a debt of imperishable gratitude. "He ended," says the author of the Memoir which has rescued so much of his life from obscurity, "he ended, as he had begun, his career in the service of his native country; infusing into her marine a spirit of lofty enterprise, a high moral tone, and a system of mild but inflexible discipline, of which the results were not long after so conspicuously displayed. Finally, he is seen to open new sources of commerce, of which the influence may be distinctly traced on her present greatness and prosperity." (See *Memoir of Sebastian Cabot, with a Review of the History of Maritime Discovery, illustrated by documents from the Rolls, now first published.* 8vo. London, 1831.)

CABRA, a town of Spain, in the province of Cordova, about 28 miles S.E. of that city. It is situated in a fertile valley near the source of the river of the same name, and contains about 1346 houses. It has a college with classes for the study of philosophy, mathematics, languages, and design, and several public and private schools. The fields of clay in the neighbourhood afford materials for a considerable trade in bricks and pottery; and there is an abundant supply of wine, vinegar, oil, and flour, from the surrounding agricultural districts. The manufacture of coarse linen, woollen, and hempen stuffs is considerable. There are some interesting Moorish remains to be seen in the town and suburbs. Pop. 9576.

CABRERA, (called by the ancients *Capraria* from the number of goats upon it), a rocky and almost uninhabited islet in the Mediterranean, belonging to the Balearic group, about 10 miles south of Cape Salinas in Majorca. In the peninsular war it was used by the English as a depot for French prisoners.

CABUL, or Caubul, a province of Afghanistan, which still retains the name by which the whole Durani kingdom was formerly known. The events which resulted in the dismemberment of the empire, will be found detailed in the article Afghanistan. Cabul proper lies between the 33d and 36th degrees of N. Lat. Its length from east to west is about 250 miles, and its breadth 150. In 1818, upon the revolution which deprived Mahmood the brother of Shah Shooja of his throne, Cabul was seized by Dost Mahomed Khan, its present ruler. Cabul, the capital of the province, and during the integrity of the empire the seat of its government, is situate on the Cabul river immediately above its confluence with that of the Logurh. The immediate vicinity of the town is highly picturesque, well watered, and fertile. It is especially productive of the finest fruits; and the beautiful gardens, orchards, and groves are a source of great delight to the citizens during the fine season. A recent traveller who had often joined their festive parties, thus describes the environs of the beautiful site of the tomb inclosing the remains of the illustrious emperor Baber:[1]— "Baber Badshah, so the interesting spot is called, is distinguished by the abundance, variety, and beauty of its trees and shrubs. Besides the imposing masses of plane-trees, its lines of tall, tapering, and sombre cypresses, and its multitudes of mulberry trees, there are wildernesses of white and yellow rose-bushes, of jasmines and other fragrant shrubs. The place is peculiarly fitted for social enjoyment, and nothing can surpass the beauty of the landscape, and the purity of the atmosphere." The river of Cabul, though giving name to the great body of water which is poured into the Indus at Attock, adds nothing to the charms of the landscape, being here a small and dirty stream. The city, about three miles in circuit, is not wholly surrounded by a wall, being defended on the western side merely by a line of weak ramparts running from one hill to another, and of course affording no defence if turned. It stands at the western extremity of a plain of considerable extent, and in a recess formed by the junction of two ranges of hills. The houses are in general two or three stories high, built of sun-dried bricks with a large admixture of wood, as a security against the shocks of earthquakes. Four spacious bazaars were erected here in the centre of the city, by Ali Murdan Khan, a celebrated Persian nobleman, who for many years governed the western provinces; but these were demolished by the British in retribution of the murderous treachery of the inhabitants. The citadel called Bala-Hissar, or upper Fort, is situate on a rising ground in the eastern quarter of the city, and contains the palace. The mosques and other public buildings have nothing to recommend them in an architectural point of view. There is but one college, and it has been allowed to fall into decay. The serais, or public buildings for lodging and entertaining strangers, are about fifteen in number, and are remarkable neither for elegance nor convenience. There are several public baths, repulsive alike from want of cleanliness and from offensive smell, originating in the nature of the fuel used for heating them. Water is sufficiently supplied, both for the irrigation of the adjacent country and for domestic purposes, by the Cabul river.

This river is crossed by three bridges. One, the Pul Kuhto, is in the middle of the city, and is substantially built of brick and stone; another, the Pul Noe, is a frail fabric of wood, trembling under the weight of foot-passengers, who alone can cross it; a third, to the west of the town, is a fortified bridge, crossing the river where it passes through the gorge between the hills which bound the city on that side, and by this means the lines are continued across the stream. The climate, from the vicinity of the great central range of the Hindu Koh mountains, covered with perpetual snow, and from the great elevation of the town, which is situate 6396 feet above the level of the sea, is severe, the winter setting in at the beginning of October and continuing to the end of March. During this season the more opulent inhabitants rarely stir out, spending their time in such sedentary indulgences as they can command. Cabul is a place of considerable trade. The city is mentioned by the Arabian historians of the seventh century as a residence of a Hindu prince. It was for some time the capital of the emperor Baber, and in the year 1739 was taken by Nadir Shah, who annexed it with the province to his Persian dominions. On his death Ahmed Shah Abdally, the founder of the Durani empire, took possession of it, and in the year 1774 it was constituted the capital of Afghanistan by his son Timour Shah, and so remained till the downfall of the short-lived dynasty, when, as above noticed, it was seized by Dost Mahomed Khan, who for some time maintained an unquiet and precarious rule.

In 1839, a British army marched into Afghanistan, to restore to the throne Shah Shooja, who took possession of the city of Cabul and retained it until the commencement of 1842, when a dreadful outbreak of native fury and perfidy deprived them of it. The chief civil officer, Sir William Macnaghten, was basely assassinated, the troops cut off from their magazines and stores, and compelled to attempt a retreat under circumstances which rendered its successful accomplishment hopeless. Of 3849 soldiers and about 12,000 camp-followers, only one European, severely wounded, and four or five natives, escaped. In the same year a British army took the town, recovered some prisoners, including the heroic Lady Sale, wife of Sir Robert Sale, and having destroyed the principal bazaar and some other public buildings, returned leaving the place to its fate. The po-

[1] *Narrative of various Journeys in Beluchistan, Afghanistan, and the Punjaub*, by Charles Masson. London, 1842.

pulation of Cabul is about 60,000. Lat. 34. 30. Long. 69. 6.

CACAO or COCOA, the substance prepared from the seeds of the *Theobromia cacao*. When the bruised seeds are flavoured with the *Epidendrum vanilla*, mixed with a little sugar, they form the agreeable confection well known under the name of *chocolate*.

CACERES, a province of Spain, forming, by the division of 1833, the northern half of the old province of Estremadura. It is bounded north by Salamanca and Arvila, east by Toledo and Ciudad-Real, south by Badajos, and west by Portugal, embracing an area of 615 Spanish square leagues. It contains 13 *partidos*, 226 *ayuntamientos*, 3 cities, 122 towns, and 100 villages. Pop. (1849) 264,988. See ESTREMADURA.

CACERES, the capital of the above province, on the left bank of the Tagus, on a ridge of hills which stretch from east to west, 24 miles west of Truxillo. It is the residence of the Bishop of Coria, and contains a handsome episcopal palace. The monastery and college of the Jesuits was one of the finest in the kingdom, but has been secularized and converted into an hospital. It has a public school, a college with professorships of grammar, rhetoric, mathematics, philosophy, moral and scholastic theology, &c., a foundling hospital and several other charitable institutions. In the neighbourhood are large gardens, well cultivated fields, and extensive pasture grounds; while in the town are numerous oil and fulling mills, soap-works, and lime-kilns. It occupies the site of the ancient *Castra Cæcilia*, and was a place of some importance both under the Romans and the Moors. Pop. 12,051.

CACHALOT, the spermaceti or sperm whale (*Physeter macrocephalus*). See index to MAMMALIA.

CACHAO, KACHO, KECHO, or BAK-THIAN, the largest city of Anam, and the capital of the province of Tonquin, in Asia, situated on the west side of the Tonquin river, about eighty miles from the sea. It is of great extent, and has neither walls nor fortifications, being merely surrounded by a bamboo stockade. The principal streets are wide and airy, and for the most part are paved with bricks and small stones; intermediate spaces being, however, left for the passage of elephants and other beasts of burden. The other streets are narrow and ill paved. Most of the houses are constructed of mud and timber, and thatched with leaves, straw, or reeds, and are generally one story in height. The magazines and warehouses belonging to foreigners are the only edifices built of brick; and these, though plain, yet, by reason of their height and more elegant structure, make a considerable show among the rows of wooden huts. The public edifices are very spacious, but particularly the royal palace, which is several miles in circuit, and is surrounded by high walls. It contains many buildings within its precincts, which are devoted to different purposes, and embellished with a variety of carvings and gildings after the Indian manner, all finely varnished. Besides this palace there are to be seen the ruins of one still more magnificent, which is said to have been six miles in circumference. Cachao is a great commercial resort, and its trade is facilitated by the river, which is always crowded with vessels. The imports are long cloths, chintz, arms, pepper, and other articles, which are exchanged for gold and manufactured goods, namely, beautiful silks and lackered ware, which last is generally reckoned superior to any in the East. The English factory, which stood on the banks of the river, north of the city, and that of the Dutch, south of it, have long been withdrawn. Cachao, built chiefly of wooden and brick houses, is peculiarly liable to fires; and to prevent these, or to extinguish them after they have broken out, the city is governed by a very rigid police, and is divided into wards, each subjected to a certain jurisdiction. Fires for domestic use are only permitted during certain hours of the day. About the middle of the eighteenth century the city was nearly burnt to the ground by a conflagration, which was the work of incendiaries, who discharged fire-arrows during the night against the straw-covered roofs, and the whole was in a moment in a blaze. Population estimated at about 100,000. Long. 105. 35. E., Lat. 21. N.

CACHOLONG, a peculiar variety of calcedony commonly of a milk-white colour, and transclucent. It occurs imbedded in the trap rocks of Iceland and Faro, along with calcedony, and is also found in Bukhara, on the borders of the river Cach; whence its designation. See MINERALOGY.

CACHUNDE, a medicine highly celebrated among the Chinese and Indians. It is composed of several aromatic ingredients and perfumes, made into a stiff paste, and shaped in various figures, which are dried for use.

CACOPHONY (κακός and φωνή), in *Rhetoric*, the meeting of two or more letters or syllables which produce a harsh effect.

CACTUS, a genus of endogenous plants, which are now considered as constituting a natural order, the *Cactaceæ*. They are chiefly natives of Central America; but several of them are now naturalized in the south of Spain and warmer parts of Europe, as *C. Opuntia*, which forms hedges round the fields, and produces a fruit that is much used in Spain. See BOTANY.

CACUS, the son of Vulcan, was a giant of prodigious size, who dwelt in a cave on Mount Aventine, whence he issued and plundered the surrounding country. When Hercules was returning to Italy with the oxen he had taken from king Geryon, Cacus stole some of the cattle while the hero slept; and in order to prevent discovery, he drew them backwards by their tails into his cave. Hercules, however, was attracted to the spot by their bellowing, and slew Cacus with his club. According to another tradition, the place where the oxen were confined was revealed by Cacia the sister of the robber. In commemoration of his victory, Hercules erected the *Ara Maxima*. Ovid, *Fast*, i, 554.

CADARI, or KADARI, a sect of Mahommedans, who assert free will, attribute the actions of men to men alone, not to any secret power determining the will, and deny all absolute decrees, and predestination. The author of this sect was Mabeb ben Kaled al Gihoni, who suffered martyrdom for his doctrine. The word comes from the Arabic *cadara*, power.

CADENCE, in *Music*, see MUSIC.

CADENCE, in *Reading*, a falling of the voice below the key-note at the close of a period.

CADET (French *Cadet*), the younger son of a family. In Spain it is usual for one of the cadets in great families to take the mother's name.

CADET, a military term denoting a gentleman who carries arms in a regiment as a private soldier, with a view to acquire military skill, and to obtain a commission. His service is voluntary, but he receives pay, and thus is distinguished from a volunteer. The word cadet also denotes a pupil in a military school.

CADI, or CADHI, a judge in civil affairs in the Turkish empire, usually the judge of a town or village, the judge of a city or a province being called Mollah or Moula.

CADILESCHER, a capital officer of justice among the Turks, answering to a chief justice among us.

CADIZ, one of the three provinces into which the ancient kingdom of Seville has been divided, lying between 36. 2. and 37. 0. N. Lat., and between 5. 6. and 6. 21. W. Long. It is bounded north by Huelva and Seville, east by Malaga, south by the Straits of Gibraltar, and west by the Atlantic. The eastern part, intersected by numerous sierras, which separate it from Malaga, is rocky and sterile; the western part is more level and fertile. The only river of

any importance in the province is the Guadalete, which rises in the Sierra Ronda, and falls into the Bay of Cadiz. The climate is for the most part mild and equable, and epidemics are of less frequent occurrence in this than in most of the provinces of Spain. Its industry is chiefly occupied with agricultural produce, such as grain, fruits, wine, and olives, and with the rearing of horses, asses, mules, and pigs; but in most of the maritime towns there are considerable manufactures of coarse linen and woollen goods. Pop. (1849) 358,446.

Cadiz (Latin *Gades*), the capital of the above province, is built on the extremity of a tongue of land projecting about five miles into the sea, in a direction N.W. from the Isla de Leon, in N. Lat. 36. 31., W. Long. 6. 17.; 70 miles south of Seville, and 60 N.W. of Gibraltar. The city, which is six or seven miles in circumference, is surrounded by a wall with five gates, one of which communicates with the isthmus, and is connected with the mainland by the ancient work the *Puente do Zuazo*. Seen from a distance off the coast, it presents a magnificent display of snow-white turrets rising majestically from the sea; and for the uniformity and elegance of its buildings, it must certainly be ranked one of the finest cities of Spain, although, being hemmed in on all sides by the sea, its streets and squares are necessarily contracted. The most characteristic feature of Cadiz is the marine promenades, fringing the city all round between the ramparts and the sea, especially that called the *Alameda* on the eastern side, commanding a view of the shipping in the bay and the ports which line the opposite shore. The principal square is the *Plaza de San Antonio*, surrounded by handsome houses with elegant façades, the centre pleasantly shaded with trees, and furnished with numerous ornamental seats of marble. Communicating with it is the principal street, in which are the exchange and houses of the nobility. The houses are generally lofty and well-built, with open central courts, surmounted by turrets and flat roofs in the Moorish style; but from the continual decrease of the population, some quarters of the city are falling into disrepair. The principal public buildings are the two cathedrals (one built in 1597, the other begun in 1720, but not completed till 1840); the *Hospicio o Casa de Misericordia*, adorned with a marble portico; and having an interior court with Doric colonnades; the *Plaza del Toros*, or bull-arena, the two theatres, the new prison, and the lighthouse of San Sebastian on the western side, rising 172 feet from the rock on which it stands. Besides the Hospicio already mentioned, which sometimes contains 1000 inmates, there are numerous other charitable institutions, such as the *Hospicio de Mujeres, the Casa de Espositos*, the admirable *Hospicio de San Juan de Dios*, for sick men, &c. Gratuitous instruction is given to upwards of 1000 children; and there are several mathematical and commercial academies, maintained by different commercial corporations. There is also a flourishing medical school, and an *Academia de Nobles Artes*, founded in 1789, principally by the exertions of Governor O'Reilly. There are several public libraries attached to the various educational establishments, but none of any note. Cadiz is the see of a bishop, who is suffragan to the archbishop of Seville; but its chief conventual and monastic institutions of regulars have been suppressed.

It has a museum filled only with wretched copies of ancient masterpieces; but in one of the chapels is an unfinished picture by Murillo, the last effort of his pencil, as he met his death by falling from the scaffold on which he was painting.

Its noble bay, more than 30 miles in circuit, and almost entirely land-locked by the isthmus and the headlands which lie to the N.E., has principally contributed to the importance of Cadiz. The outer bay stretches from the promontory of Rota to the mouth of the Guadalete; and the inner bay, closed by the forts of Matagorda and Puntales, affords generally good anchorage, and contains a harbour formed by a projecting mole, where vessels of small burden may discharge their cargoes. The entrance to the bays is rendered somewhat dangerous by the low shelving rocks (Cochinos and Las Puercas), which encumber the passage, and by the shifting banks of mud deposited by the Guadalete and the Rio del Santi Petri. On the mainland, at the mouth of the Santi Petri, is the Caracca, once a flourishing naval arsenal and dockyard, but now almost deserted.

The commercial greatness of Cadiz has long been on the wane. At one time it was the great focus of commercial intercourse between Spain and the Spanish colonies, and from 1720 to 1765 it enjoyed a monopoly of the traffic with Spanish America. Its prosperity began to decline when the trade of St Domingo, Cuba, Porto Rico, and the other islands was opened up to the greater ports of Spain, and decayed almost entirely in the beginning of the present century, when the colonies achieved their independence. An attempt was made by the Spanish government in 1828 to restore its former greatness, by making it a free warehousing port; but this valuable privilege was withdrawn in 1832, and commerce relapsed into its former depressed condition. By far the greatest obstacle in the way of its future prosperity is the oppressive commercial restrictions imposed by government on all imports—a policy which throws three-fourths of the trade of Spain into the hands of contrabandistas. The principal exports are wine (from Xeres) to the amount of 30,000 pipes annually, quicksilver, brandy, oil, provisions, flour, salt, wool, &c. The imports consist chiefly of sugar and coffee from the Havannah and Porto Rico, cocoa, hemp, flax, linens, dried fish, hides, cotton and woollen manufactures, rice, spices, indigo, staves, and timber. The total value of cargoes entered in 1846 was L.637,396; of cargoes cleared L.973,416, but not more than half of these were in Spanish vessels. The principal manufactures of Cadiz are soap, glass, coarse woollen, cotton and silk stuffs, and hats. There are also some sugar refineries and tanneries. A considerable stimulus to industry is given by the *Sociedad economica de Amigos del pais*, which introduced the cochineal plant, and grants medals for improvements in manufactures.

Cadiz is strongly fortified with ramparts and bastions, crowned by the forts of San Sebastian, Santa Catalina, the Muelle de San Felip, and the Muelle Principale: the isthmus is defended by an intrenchment called the Cortadura; but the fortifications are gradually falling into disrepair.

From its almost insular position, it enjoys a mild and serene climate, the mean annual temperature being about 64° Fahr., while the mean summer and winter temperatures vary only about ten degrees above and below this point. From the same cause it labours under a great deficiency of water, which must either be collected in cisterns from the tops of the houses, or brought at great expense from Santa Maria on the opposite coast. Pop. (1845) 53,922.

Cadiz is identical with the ancient Gadir or Gaddir, which was a flourishing Phœnician colony long before the beginning of classical history, and continued in the hands of the Carthaginians, though somewhat disaffected to them, till after the Punic wars, when Spain became a Roman province. C. Julius Cæsar conferred the *civitas* of Rome on all its citizens; and under Augustus, when it was the residence of no fewer than 500 *equites*, it was made a municipium under the title of Augusta Urbs Gaditana, and its citizens ranked next to those of Rome. After the fall of Rome it was destroyed by the Goths, and remained in obscurity under the Moors, from whom it was retaken by Alonzo el Sabio in 1262, but emerged again when the discovery of America made it valuable as a market for colonial produce. In more recent contests, Cadiz has been subjected to several disasters. It was taken and pillaged in 1596 by the British fleet, under Essex and Howard, in revenge for the Spanish Armada. It was attacked, but without success, by Lord Wimbledon in 1626, and by the Duke of Ormond and Sir George Rooke in 1702. It was bombarded by Nelson in 1800. In 1808, the Spanish patriots in Cadiz brought the French fleet, which lay in the bay blockaded by Admiral Collingwood, to a surrender; and they were in turn subjected to a protracted siege of two years by

Cadizadelites. || Cadmus.

Marshal Victor, from which they were relieved by the successes of Wellington in the Peninsula. It was once more reduced by the Duke D'Angoulême in 1823, and remained in the hands of the French till 1828.

CADIZADELITES, a sect of Mahommedans not unlike the ancient Stoics. They shun feasts and diversions, and affect an extraordinary gravity; they are continually talking of God, and some of them make a jumble of Christianity and Mahommedanism. They drink wine, even in the fast of the Rhamazan; love and protect the Christians; believe that Mahomet is the Holy Ghost; and practise circumcision, justifying it by the example of Jesus Christ.

CADMEAN LETTERS, the sixteen ancient Greek or Ionic characters, such as they were first brought by Cadmus from Phœnicia, whence Herodotus (v. 58, &c.) calls them also Phœnician Letters. These were—α, β, γ, δ, ε, ι, κ, λ, μ, ν, ο, π, ρ, σ, τ, υ. According to some writers, Cadmus was not the inventor, nor even the importer, but only the modeller and reformer, of the Greek letters; and it was from this circumstance they acquired the appellation of Cadmean or Phœnician Letters; whereas they had previously been called Pelasgian Letters.

CADMIUM. This metal has not yet been met with in its native state, but is contained in certain ores of zinc, and especially in the black fibrous blende of Bohemia, which contains about five per cent. of it. It was discovered by M. Stromeyer in 1817, who used the following process for separating it from its ore. He dissolved it in dilute sulphuric or muriatic acid, and, after adding a portion of free acid, transmitted a current of sulphuretted hydrogen gas through the liquid, by which means the cadmium was precipitated as sulphuret, while the zinc remained in solution. The sulphuret of cadmium was then decomposed by nitric acid, and the solution evaporated to dryness; then the dry nitrate of cadmium was dissolved in water, and an excess of carbonate of ammonia added. The white carbonate of cadmium subsided, which, when heated to redness, yielded a pure oxide; and by mixing this oxide with charcoal, and exposing it to a further heat, metallic cadmium was obtained in the form of sublimation. Dr Wollaston's process is somewhat more simple: he placed the solution of the mixed metals in a platinum capsule along with a piece of metallic zinc. If cadmium be present it is reduced, and adheres to the capsule; after which it may be dissolved, either by nitric or dilute muriatic acid.

The cadmium thus obtained has in colour and lustre a strong resemblance to tin, but is somewhat harder and more tenacious. It is very ductile and malleable; melts at about the same temperature as tin; but is nearly as volatile as mercury, condensing like that metal into globules which have a metallic lustre. When heated in the open air it absorbs oxygen, and is converted into an orange-coloured oxide. It is readily dissolved by nitric acid, but is less easily acted upon by sulphuric and muriatic acids. Its specific gravity is 8·62.

Cadmium appears to exist in those ores in the state of a sulphuret. It has since been found in the yellow zinc blendes of Mexico, and was still more recently discovered by Lord Greenock (now Earl Cathcart), in a porphyritic greenstone near Bishoptown in Renfrewshire. This last occurs in detached prismatic crystals of a rich orange-yellow colour. It consists of cadmium 77·6, sulphur 22·4, and has been named *Greenockite* in honour of its discoverer.

CADMUS, in *Fabulous History*, king of Thebes, the son of Agenor king of Phœnicia, and the brother of Phœnix, Cilix, and Europa. According to tradition, he carried into Greece the sixteen simple letters of the Greek alphabet; and there he built Thebes, in Bœotia. The poets relate that Cadmus left his native country in search of his sister Europa, whom Jupiter, in the form of a bull, had carried away; and that, on inquiring of the Delphic oracle for a place to settle in, he was answered that he should follow the direction of a cow. When Cadmus arrived in Phocis, he found the cow described by the oracle; and following her into Bœotia, he built the city of Thebes as he had been directed on the spot where she sank down. Intending to sacrifice his guide to Pallas, he sent two of his company for water to the fountain Dirce, where they were devoured by a serpent or dragon. Cadmus slew the monster, and afterwards, by the advice of Pallas, sowed its teeth, from which sprung up a number of armed men, who prepared to revenge the death of the serpent; but on his casting a stone among them, they turned their weapons against each other with such animosity that only five survived the combat. This remnant assisted Cadmus in founding his new city. Afterwards, to recompense his labours, the gods gave him Harmonia, the daughter of Mars and Venus, for his wife, and honoured his nuptials with presents and peculiar marks of favour. Subsequently Cadmus and Harmonia quitted Thebes, and went to the Euchelians, who made Cadmus their king. Lastly, Cadmus and his wife were transformed into serpents; or, as others say, were translated to the Elysian fields in a chariot drawn by serpents.

Cadmus || Cælius.

CADMUS of Miletus, the earliest Greek historian who wrote in prose. He flourished about B.C. 540. (Plin. *Hist. Nat.* v. 31; Strabo, i., p. 18.)

CADRITES, a sort of Mahommedan friars, who once a-week spend a great part of the night in turning round, holding each other's hands, and repeating incessantly the word *hai*, which signifies *living*, and is one of the attributes of God; during which one of them plays on a flute. They never cut their hair, nor cover their heads, and always go barefooted. They have liberty to quit their convent when they please, and to marry.

CADUCEUS, in *Antiquity*, the rod or sceptre borne by Hermes or Mercury, as the ensign of his quality and office. This rod was entwisted by two serpents, and generally surmounted with a pair of wings. The rod represents power; the serpents, wisdom; and the wings, diligence and activity. Wonderful properties were ascribed to the caduceus by the poets; as laying persons asleep, raising the dead, and such like marvels. See MERCURY.

The staff or mace carried by heralds and ambassadors in time of war was called caduceus (in Greek κηρύκειον or κηρύκιον). It was originally an olive branch, the twigs of which came afterwards to be represented as serpents. Later mythologists invented various tales about these serpents. The ambassador sent to treat of peace was called *caduceator*, from the caduceus or mace which he carried in his hand. The Roman Fetiales, however, on such occasions, did not use the caduceus, but carried the sacred herbs gathered from within the inclosure of the Capitoline hill. The caduceus is frequently represented on medals, &c., as a symbol of good conduct, peace, and prosperity.

CADUS (κάδος), in *Antiquity*, a large vessel, generally of earthenware, used for containing wine and other liquids. As a measure for liquids it was synonymous with the Attic amphora, usually equal to 1½ Roman amphoræ, or about eight gallons and five pints English.

CADUSII, in *Ancient Geography*, a warlike mountain-race of Media Atropatene, inhabiting the hilly country on the S.W. shores of the Caspian Sea; between whom and the Medes a perpetual feud continued down to the time of Cyrus the Elder.

CÆLIUS or CŒLIUS, AURELIANUS, a very celebrated Latin physician, and the only one of the sect of the Methodici of whose works we have any remains. It is supposed that he was a native of Sicca in Numidia, and probably lived in the third century. He had carefully studied the ancient physicians of all sects; and to him we are indebted for a knowledge of many dogmas that are not to be found but in his work on *Acute and Chronic Diseases*. The best edi

tion, perhaps, is that by Amman, Amstel., 1709, 4to. Cælius also wrote several other works, but these have perished.

CAEN, the capital of the arrondissement of the same name, in the department of Calvados in France. It stands in an extensive valley, on the left bank of the Orne, at the influx of the Odon, 9 miles from the English Channel, and 122 west of Paris. Lat. 49. 11. 12. N., Long. 0. 21. 38. W. The town is handsome and well built; the streets are generally wide, straight, and clean; and the houses, being built of freestone, have a very good appearance. The city contains several ancient churches and other edifices, fine specimens of the Norman style of architecture. Among these are the church of St Pierre, which is surmounted by a handsome stone spire, the finest in Normandy, and which is 242 feet in height; the churches of the *Abbayes*, *Aux Hommes*, and *Aux Dames*, both founded in 1066, the former by William the Conqueror, where a plain gray marble slab in the pavement now marks his tomb, which, however, has long since been emptied; and the latter by his queen Matilda, who was interred there. Caen is the seat of a high court of appeal for the departments of Calvados, Manche, and Orne, and has tribunals of primary instance and commerce, a chamber of commerce, a *conseil de prud 'hommes*, a university, a royal college, a school of hydrography, an institution of deaf-mutes, a public library of 45,000 volumes, an extensive botanic garden, and a theatre. Population (1851) 40,569; while that of the arrondissement amounted to 139,922. The commerce and manufactures of Caen are considerable. It exports corn, wine, brandy, fruit, cattle, stones, hardware, &c. Its manufactures consist chiefly of laces, caps, table-linen, cotton fabrics, earthenware, cutlery, &c.; it has also breweries, dye-works, and shipbuilding yards. Several large fairs are annually held here. At high water, vessels of 150 or 160 tons can come up to the town, and a canal to connect it with the sea is in course of construction, which will render it accessible to large vessels.

Though Caen is not a town of great antiquity, yet the date of its foundation is unknown. In the ninth century it existed under the name of Cathem or Catham; and when in 912 Neustria was ceded to the Normans by Charles the Simple, it was a large and important city. Under the Dukes of Normandy, and particularly under William the Conqueror, it rapidly increased. This last prince, with his spouse Matilda, contributed much to its embellishment. It became the capital of Lower Normandy, and in 1346 was besieged and taken by Edward III. of England. It was again taken by the English in 1417, and retained by them till 1459, when it capitulated to the French, in whose possession it has since continued.

CÆRE (Καῖρε), called by the Greeks *Agylla* (Ἄγυλλα), a city of Southern Etruria, near the coast of the Tyrrhenian Sea. Its site is occupied by the modern *Cervetri* (*Cære vetus*). From the inhabitants being admitted to the privilege of Roman citizens, but without the right of suffrage, the *Cærite franchise* came to be a proverbial expression denoting disfranchisement. Interesting Etruscan remains have been found in the tombs of Cære. (See Dennis' *Cities and Cemeteries of Etruria*, vol. ii.)

CAERLEON, a market-town in the parish of Llangattock, and hundred of Usk, Monmouthshire, stands on the right bank of the river Usk, N. Lat. 51. 37., W. Long. 2. 56.; 2 miles N.E. of Newport, and 148 miles west from London. It covers an area of 450 acres, partly on the site of the ancient *Isca Silurum*, the station of the second *legion* (of which *leon* is a contraction), and is thought at one time to have been the capital of Wales. It is an old and irregular town, with an ancient parish church (St Cadoc's), and three other places of worship, besides an endowed, a national, and an infant school. The iron and tin-plate works give employment to a large number of the inhabitants, but otherwise there is little trade of any description in the place. In the neighbourhood are the remains of the Roman city, with outworks, a fortress, and an amphitheatre since called Arthur's Round Table. And a great variety of antiquities, chiefly Roman altars, pavements, tiles, coins, medallions, &c., have been dug up in the vicinity, and are deposited in a museum erected for that purpose in the town. Caerleon was the seat of an ancient archbishopric, afterwards removed to St David's. Pop. (1851) 1281.

CAERMARTHEN, or CAERMARTHENSHIRE (Welsh *Caerfyrddin*), a maritime county in South Wales, is bounded on the north by Cardigan, on the east by Brecon, on the south by Glamorgan and the Bristol Channel, and on the west by Pembroke. Its greatest length is from S.W. to N.E., about 52 miles; its greatest breadth, S.E. to N.W., about 28 miles. It possesses an area of 947 square miles, or 606,331 acres, and is thus the largest of all the Welsh counties. It contains 77 parishes, and is in the diocese of St David's. It derives its name from Merlin (Welsh *Myrddin*) the famous wizard, who was a native of this county.

The whole of the northern, and by far the largest portion of Caermarthenshire, is chiefly occupied by the Silurian geological formation. To the south of this, and crossing the county in a direction from S.W. to N.E., there stretches a belt of the old red sandstone, varying in width from 1½ to 4 or 5 miles. This is succeeded on its southern edge by narrow belts of the carboniferous limestone, and the millstone grit; south of which the whole remaining portion of the county is occupied by the coal measures, forming part of the great South Wales coalfield.

In the S.E. there is a range of bleak and somewhat lofty mountains, called Mynydd du, or the Black Mountains. In the east, adjoining the border of Breconshire, the Caermarthenshire Van, the third highest mountain in South Wales, rears its lofty summit. The rest of the county is thickly studded with rounded green hills; but few of these exceed 1000 feet in height.

The valleys of the Teivy (Welsh *Teifi*) and the Towy (Welsh *Tywi*) present scenes of great beauty and interest. From Grongar hill and the ruins of Dynevor Castle the picturesque beauties of the vale of the Towy are seen to great advantage. The whole of the county is intersected in every direction by narrow valleys and deep glens, from which the hills rise abruptly. The scenery in the neighbourhood of Caermarthen is seen to great advantage from Abergwili, the residence of the bishop of St David's, about two miles from the town.

The principal rivers are the Towy (Welsh *Tywi*), which rises in Cardiganshire, and enters the county at Capel Ystradfin in the N.E.; thence it flows S.W., and in its course passes through the towns of Llandovery, Llangadock, Llandeilofawr, and Caermarthen; and after forming the harbour of the latter place, falls into Caermarthen bay in the Bristol Channel. The Teivy (Welsh *Teifi*) rises in Llyn Teifi in Cardiganshire, and forms the boundary between Caermarthen and Cardigan shires, from Lampeter to Cenarth, near Newcastle Emyln. The Tave (Welsh *Taf*), which rises in Pembrokeshire, near Llanfirnach, enters the county near its western boundary, and flows S. and S.E.; and after forming the harbour of Laugharne, falls into Caermarthen bay. Besides these, there are several smaller streams, as the Cothi, the Dewi, the Feni, the Gynin, the Gwili, the Dulais; the Gwendraeth Fawr, which forms the port of Kidwelly; and the Llwchwr, which separates the county from Glamorganshire for about ten miles, and forms the port of Llanelly.

The bay of Caermarthen is the finest in the Bristol Channel. It is about 18 miles across its mouth, from the Worm's head in Glamorgan on the east to Giltar head in Pembroke on the west. It is about 12 miles in depth, and affords good anchorage and shelter for vessels navigating the channel.

There is an inlet of the sea in this bay on the east, called the Burry river, which leads up to the port of Llanelly. Between the Burry and the mouth of the Towy, there is a somewhat dangerous sand-bank called Cefn Sidan.

The port of Caermarthen is only frequented by small coasters, owing to the difficulties of the navigation, and the bar at the mouth of the Towy; but at Llanelly vessels of 600 or 700 tons can enter, and a vigorous trade in coals, iron, copper, and copper ore is carried on.

The climate is mild, except in the very elevated parts of the county; but the annual fall of rain is very great. Agriculture is generally in a very backward condition; but there is now some progress being made in efficient drainage under the provisions of the drainage acts, and better modes of agricultural practice will no doubt follow. The soil varies very much; but in the southern parts of the county, and in the larger valleys, it is exceedingly fertile. The cultivated crops consist of wheat, oats, barley, turnips, and potatoes. There is a good deal of cultivation on the lower hills; but the more elevated are chiefly in heath or mountain pastures. The breed of horses is celebrated; and these, with cattle, sheep, wool, butter, and pigs, are largely exported to the neighbouring districts. It is calculated that about two-thirds of the lands only are inclosed.

In the S.E. there are extensive and valuable coal and iron mines, and there are also some important lead mines in the county. Limestone is also abundant in the south.

The South Wales railway traverses the county in the S. and S.W.; and there is also a line from Llanelly to Llandeilofawr, with several branches. There are besides numerous canals and tramways for the accommodation of the mines. The principal towns are Caermarthen, Llandeilofawr, Llangadock, Llandovery, Newcastle Emlyn, Laugharne, Llanelly, and Kidwelly. The county has returned two members to parliament since 1832, having only had one from 1536 up to that time. The political influence is chiefly in the hands of Lord Cawdor, although Lord Dynevor has much weight in the county. Constituency in 1852, 4791. The average gross estimated rental of the county is 10s. 1d. per acre. The annual value of real property paying income-tax is L.396,915.

The population of the county at the last census was 110,632, giving an average of 117 persons to a square mile, or 5·5 acres to each person. Of the total number, 53,076 were males and 57,556 females. The number of inhabited houses was 22,465; uninhabited, 1176; and building, 99; giving an average of 24 inhabited houses to a square mile, and 4·9 persons to a house. The following table gives the census returns for the last 50 years:—

YEARS.						Increase of population per cent. in fifty years.
1801.	1811	1821.	1831.	1841.	1851.	
67,317	77,217	90,239	100,740	106,326	110,632	64

It is calculated that about one-fifth of the whole population are in the condition of labourers, servants, &c. About fourteen per cent. live by agriculture, and rather more than eight per cent. by trade, manufactures, &c. Nearly four thousand persons possess independent means, while seven hundred follow professions.

In 1847 the total number of children of the working classes at day schools within the county was 7191. The total number of schools was 179; of which 61 were Church or National, with 3170 scholars; 4 British and Foreign, with 456 scholars; 8 Baptist, with 308 scholars; 15 Independent, with 581 scholars; 5 Calvinistic Methodist, with 133 scholars; 1 Wesleyan, with 10 scholars; 75 Adventure or Private, with 2186 scholars; 5 Workhouse schools, with 138 scholars; 2 Workmen's, with 95 scholars. The average annual income of each school was L.23, 5s., and the average annual income of the teachers from all sources only L.20, 15s. 1d. The total number of scholars attending Sunday-schools was 28,313. The total number of Sunday-schools was 308; of which 48 were Church of England, with 3837 scholars; 78 Calvinistic Methodist, with 7411 scholars; 110 Independent, with 11,962 scholars; 55 Baptist, with 4006 scholars; 14 Wesleyan, with 983 scholars; 3 other denominations, with 114 scholars. In 140 of these schools instruction was given in Welsh only, in 19 in English only, and in 149 in both tongues.

Welsh is the language commonly spoken by the lower orders, and in the northern parts of the county the manners and customs of the people are as purely Welsh as in any part of the principality. It was in this county that the remarkable "Rebecca" insurrection originated in 1843–4. The multiplicity of toll-gates seemed to be the original cause of this singular conspiracy. Parties of five or six hundred men, mostly mounted, armed with pickaxes, sledges, hatchets, and guns, used nightly to traverse the counties of Caermarthen, Pembroke, Cardigan, and Brecon, headed by a tall man dressed in women's clothes, throwing down the toll-gates, and committing other excesses; and so well did the rioters keep counsel, and so secretly did they manage their forays, that despite the exertions of the magistrates, assisted by large bodies of military sent into the districts, no effectual check could be put upon their proceedings for many months. The course usually pursued by them was to assemble quickly and secretly in the neighbourhood of some obnoxious toll-gate; the leader then addressed to them the inquiry, "My children, this gate has no right to be here, has it?" Upon which the attack commenced, and in a few minutes not a vestige of gate or toll-house remained standing. From pulling down toll-gates, the rioters proceeded to redress all other real or imaginary grievances. On one occasion they destroyed a weir in the Teifi, about which there had been a long feud between the proprietor and the fishermen. On another occasion they murdered a poor old woman who kept a toll-gate. The daring and courage with which they executed the commands of their leaders, and the ingenuity they displayed in outwitting those sent against them, form altogether a remarkable episode in the history of the principality. On more than one occasion they destroyed the restored toll-gates within earshot of the military sent to protect them; and having discovered the secret signals agreed on between the magistrates and military, they used to harass the latter by exhibiting them at the most unseasonable hours. Thus a magistrate having arranged that if his house were attacked he was to exhibit three lights, the Rebeccaites, who had discovered this, gave the signal so often in the night, that the patience of both officers and men was fairly exhausted with the false alarms.

Caermarthenshire is rich in antiquities, and possesses the remains of three important Roman roads.

CAERMARTHEN, or CARMARTHEN (Welsh *Caerfyrddn*), the capital of the county of the same name, a market and borough town 183 miles north by west from London, beautifully situated in the vale of the Towy. The river is navigable up to the town, and there is a considerable export trade carried on in tin-plates, cast-iron, slates, timber, and agricultural produce. Owing to the disgracefully neglected state of the river, only vessels of moderate draught can enter; and indeed, masters of vessels have generally an objection to freights for this port. It is now probable, since the South Wales railway has been opened, that the shipping trade of Caermarthen will fall into a state of decay.

The streets are generally narrow, but the houses are well built, and altogether the town has the appearance of a place of considerable importance. The church of St Peter's is a venerable edifice. and contains some curious monuments,

among which is that of the celebrated Sir Rhys ap Thomas and his lady. Sir Richard Steele is also buried here. There is another church belonging to the Establishment called St David's, a plain structure. There are two Baptist, two Wesleyan, two Independent, one Unitarian, and two Calvinistic Methodist chapels. There is a large and well conducted training college here for Welsh teachers; and there are two grammar-schools on public foundations. There are also two infirmaries, and a literary and scientific institution, the lectures at which are well attended. The town also possesses a county-hall and a handsome new music-hall. The county gaol is built on the site of the very ancient castle. There is a granite obelisk erected to the memory of Sir Thomas Picton, and a bronze statue to General Nott, who were both natives of the town.

Caermarthen has figured as an important place from the earliest period. It was the Maridunum of the Romans, and is supposed to have derived its present name from Caer, a fortified place, and Myrddin, the British name of the celebrated wizard Merlin, who was a native of the place. It gives the title of Marquis to the Duke of Leeds.

The corporation consists of a mayor, 6 aldermen, and 18 councillors. It returned a member to parliament for itself from 1536 to the period of the Reform act. Since that time it has been associated with Llanelly in returning one member; constituency in 1832, 684; in 1852, 849. The political influence is chiefly in the hands of Earl Cawdor. The assessed taxes yield annually L.2192, and the annual value of real property paying income-tax is L.55,250. There are markets on Wednesdays and Saturdays, and several fairs in the course of the year. The quarter sessions and assizes are held here. Pop. in 1851 10,524; inhabited houses 1800.

CAERNARVON or CARNARVONSHIRE (Welsh *Caer-yn-arfon*), a maritime county of North Wales, is bounded on the north by Beaumaris Bay; on the east by Denbigh; on the S.E. by part of Merioneth; on the S.W. by Cardigan Bay, and on the west by the Irish Sea and the Menai Straits. There are two small detached portions of the county on the north coast of Denbighshire; one of these forms the Great Ormes Head; and the other is a few miles further east. The greatest length of this county is from N.E. to S.W., and, exclusive of the detached portions, it measures about 53 miles; its greatest breadth from S.W. to N.E. is about 23 miles. Nearly one-half of its whole length forms a peninsula varying from five to nine miles in width, projecting in a S.W. direction into the Irish Sea, and forming Cardigan bay on the south, and Caernarvon bay on the north. This county possesses an area of 579 square miles, or 370,273 acres, and is thus the ninth largest of the Welsh counties. Arfon was the original name of this district, and from this, and Caer—a fortified place—the present name is derived.

The lower Silurian and Cambrian beds may be termed the basis of the geological features of this county; but they are so completely penetrated in every direction by intrusive igneous rocks, that there is hardly a square mile of surface in the whole county free from their presence. These consist chiefly of compact felspar, felspathic traps, greenstone, and quartz prophyries. On the west, along the shore of the Menai Straits, there is a narrow belt of carboniferous limestone; of this the Great Ormes Head is also composed; and on the western side of the peninsular part of the county is a broad band of chlorite and mica schist. Caernarvon is rich in mineral treasures; for besides lead and copper lodes, its numerous slate quarries are amongst the most valuable mineral properties in the united kingdom, and yield princely incomes to the fortunate possessors, besides furnishing employment to many thousands of workmen. It is calculated that the workmen and their families who are supported by the slate quarries of Col Pennant alone number fully 12,000 people.

Caernarvon is the most mountainous of all the Welsh counties, and its mountains are the grandest of any in the British islands south of the Forth. The Snowdon range fills up the whole of the centre of the county; and, with its lofty summits rising to the height of between three and four thousand feet, throws an air of grandeur and sublimity over the scenery, which is of the most romantic and beautiful description. The summit of Snowdon itself is 3571 feet above the level of the sea, and it is surrounded by a phalanx of giants, many of them but little lower than itself. Among the more important of these, within the county, are the Glyder Fawr, 3300 feet; the Glyder Bach, 3000 feet; the Moel Siabod, 2878 feet; Moel Hebog, 2584 feet; Aran, 2473 feet; Craig Goch, 2350 feet; Carnedd Dafydd, 3427 feet; and Carnedd Llewelyn, 2460 feet in height. The upper part of the mountain is generally enveloped in clouds. The rocks of which the Snowdonian range is composed are for the most part of a very bold and rugged description, which adds to the impressiveness of their immense masses.

Some of the valleys are characterized by the extreme of wild and rugged grandeur, being walled in by naked rocks, and traversed by foaming torrents dashing through them with angry roar and race-horse speed; while others are marked by soft and smiling beauty. Among the former may be mentioned the gorge at Pont Aberglaslyn, while Nant Gwynant with its placid lake and verdant meadows will serve as an illustration of the latter. The vales of Beddgelert and Llanberis, the former at the southern, and the latter at the northern base of Snowdon, have a world-wide reputation for beauty; and the vale of the Conway from Llanrwst to Conway is a noble piece of scenery, backed as it is on its southern border by the Snowdon range.

The only river of importance in the county is the Conway (Welsh *Conwy*). It rises in Llyn Conwy, in the S.E. corner of the county; and after separating Caernarvon from Denbigh, in a nearly due north course of about 30 miles, falls into the sea at Conway. It is a tidal river, and navigable for about 10 miles from Conway. The Seoint, a small stream, rises in Snowdon, and falls into the sea at Caernarvon.

The lakes are very numerous, and some of them are of considerable size. The more important are the lakes of Llanberis, to the north of Snowdon; Llyn Ogwen to the north of the Glyder Fawr; Llyn Cwlyd, and Llyn Eigiau, both to the north of Capel Careg; Llyn Llydau on Snowdon; Llyn Cwellyn to the east, and Llyn Gwynant to the west of that mountain; Llyniau Nant y Clef near Llanllyfin; and Llyn Conwy, already referred to.

The climate is cold and severe during the winter, except in the peninsular part of the county and on the sea-coast, where it is very mild. The arable land occupies not more than one-fortieth part of the whole surface; and this is mostly in the vale of Conway, or in the neighbourhood of the sea. A small quantity of wheat is raised; but the principal cultivated crops are barley, oats, and bere. The alluvial deposit in some of the valleys forms a rich and fertile soil, which is chiefly employed as meadow land. Dairy and sheep-farming form the chief employment of the agricultural population; and on the hills great numbers of diminutive ponies are reared, which at two years old find a steady sale in the English market. Agriculture is in a very backward state; and the farmers are a very poor ignorant race of men, without capital or energy, but very industrious and saving; often living more penuriously than the poorest day labourer. The farm buildings and cottages throughout the greater part of the county are of a very wretched description.

A railway has lately been opened from Bangor to Caernarvon along the coast, and there are admirable private railways worked by locomotive power laid down through the

Caernarvon. mountains from the slate quarries to the ports of shipment, at each of which—Bangor, Port Dinorwic, Caernarvon, and Portmadoc—a prodigious amount of shipping is employed, in transporting the slates to different parts of the kingdom, to the continent of Europe, and to America. This county boasts of possessing some of the grandest works of scientific skill in existence—the Menai and Conway suspension bridges, constructed by the celebrated Telford as parts of the Great Holyhead road from London; and the famous tubular bridges constructed by Mr Robert Stephenson for carrying the Chester and Holyhead railway over the estuary of the Conway and the Menai Straits.

The principal towns are Conway (Welsh *Aberconwy*), Bangor, Caernarvon, Pwllheli, Criccieth, and Tremadoc, all on the coast. The county returns one member to parliament, and has done so since 1536. The political influence is chiefly in the hands of the Marquis of Anglesey and Mr Douglas Pennant—the owner of the Bangor slate quarries. Constituency in 1852, 1913. The average gross rental of the county is 8s. 7d. per acre; and the annual value of real property paying income-tax is L.251,044.

The population of the county, by the last census, was 87,870; giving an average of 151 persons to a square mile, or 4·2 acres to each person. Of the total number, 42,978 were males, and 44,892 females. The number of inhabited houses was 18,005; uninhabited, 590; building, 132; giving an average of 31 inhabited houses to a square mile, and 4·9 persons to a house. The following table gives the census returns for the last 50 years:—

YEARS.						Increase of population per cent. in fifty years.
1801.	1811.	1821.	1831.	1841.	1851.	
41,521	39,655	58,099	66,818	81,093	87,870	111

It is calculated that about a fourth part of the whole population are in the condition of labourers, servants, &c. About 12 per cent. live by agriculture, and about 7 per cent. by trade; while upwards of 2000 persons possess independent means, and about 400 follow professions.

In 1847 the total number of the children of the working classes at day-schools within the county was 5867. The total number of schools was 79, of which 47 were Church or National, with 3994 scholars; 5 British and Foreign, with 695 scholars; 5 other denominations, with 378 scholars; 1 Workhouse, with 36 scholars; and 21 Adventure, with 764 scholars. It appears that the average annual income of each teacher from all sources was L.33, 2s. 9d. The total number of Sunday-schools was 236, with 26,763 scholars; of these, 16 were Church of England, with 1455 scholars; 17 Baptist, with 1174 scholars; 131 Calvinistic Methodist, with 18,071 scholars; 49 Independent, with 3998 scholars; and 24 Wesleyan Methodist, with 2065 scholars. In 200 of these schools instruction was given in the Welsh language only; 6 in the English language only; and in 24 in both tongues; in 6 not ascertained. Nearly the whole population use the Welsh language habitually, and their manners and customs are for the most part purely Welsh.

Caernarvon or Carnarvon (*Caerynarfon*), the capital of the county of the above name, a market and borough town, 210 miles N.W. from London, pleasantly situated on the eastern shore of Caernarvon Bay, in the Irish Sea, at the mouth of the Seoint. There are some handsome streets, and many of the houses are large, well-built, and excellent. This town has long been famous for the celebrated castle of Edward I., in which Edward II. was born, as arranged by his astute father, in the hope of attaching the turbulent Welsh chieftains to a prince born in their own land. This splendid pile is situated at the S.W. corner of the town, close on the beach, and although entirely unroofed, possesses a grand and imposing appearance. A considerable portion of the town wall near the castle is still entire. The parish church is nearly half a mile from the town. In the town itself there is a chapel of ease, and several large and commodious dissenting chapels. There are also a town and county hall, a training college for teachers, and handsome schools. The town also possesses assembly rooms and a theatre.

Caerphilly ‖ Caerwys.

The borough has formed part of a district which has returned a member to parliament since 1536. The Reform bill added Bangor to the district, which still returns one member. The contributing boroughs are Caernarvon, Conway, Criccieth, Pwllheli, Bangor, and Nevin. Constituency in 1852, 861. The political influence is in the hands of Colonel Douglas Pennant and Mr Assheton Smith. The assessed taxes yield annually L.2498. The annual value of real property paying income-tax is L.36,503. Pop. in 1851, 8674. Inhabited houses 1723. There is a weekly market on Saturdays, and four fairs in the course of the year. The quarter sessions and assizes are held here. There is a considerable trade carried on in slates. The coasting trade, shipbuilding, and fisheries, also employ a considerable number of the inhabitants.

CAERPHILLY, a town of Wales in the county of Glamorgan, situated between the rivers Rumney and Taf, 7 miles N.W. of Cardiff, and about 165 miles from London. It was formerly a borough and a place of considerable importance, but was disfranchised in the reign of Henry VIII. In the immediate neighbourhood of the town are the ruins of the old castle, which was originally one of the most magnificent baronial strongholds in the kingdom. This fortress was built towards the close of the thirteenth century by Gilbert de Clare, and subsequently passed into the hands of the Mortimers, lords of Glamorgan. From them it was wrested by Hugh Despenser, the favourite of Edward II., who was here besieged by his rebellious barons. The most remarkable portion of the ruins as they now exist, is an old tower called the "mint," which stands ten feet off the perpendicular. Some of the houses of the town itself are very ancient, but the majority of them are comparatively modern. The surrounding scenery is among the finest in South Wales. Considerable manufactures of woollen stuffs are carried on, and occupy a large number of the population, to many of whom also the mines and quarries in the neighbourhood give employment. There is one Episcopal chapel, and three dissenting places of worship. Market-day, Thursday. Pop. (1851) 952.

CAERSWS, a town of North Wales in Montgomeryshire, situated on the Severn, 6 miles N.W. of Newton. During the Roman occupation of Great Britain, it was one of the most important stations which that people had in Wales, and is now chiefly interesting as exhibiting many important Roman remains. One of the camps, that may still be traced in the neighbourhood, covers four acres. Coins, urns, vases, &c. are from time to time turned up in the vicinity. Pop. about 500.

CAERWENT, a town of England in the county of Monmouth, four miles from Chepstow. It was known to the Romans as Venta Silurum, and is situated on the Via Julia or Akeman Street. Like many unimportant towns in this part of the country, it exhibits interesting remains of the Roman occupation. Of these the most important are the ruins of the old wall, nearly 600 yards on one side and 400 on another, from 12 to 20 feet in height, and from 6 to 12 in thickness. Large numbers of Roman coins, statues, and inscriptions, are from time to time dug up in the neighbourhood. Caldecott Castle, the seat of the once powerful family of the Bohuns, is in the immediate vicinity.

CAERWYS, a borough and market-town in the hundred of Rhudd, in Flintshire, North Wales, 204 miles from London. It is situated on a rising ground, and consists chiefly

of four principal streets, which intersect each other at right angles. It is a contributary borough to Flint. Market-day Tuesday. Pop. (1851) 635. The celebrated congress of the Welsh bards used to be held in this town. The last of these meetings took place in May 1798.

CÆSALPINUS, ANDREAS, one of those great and daring geniuses who, contending with the mists of a dark age, elicit the most brilliant truths on the one hand, whilst they sometimes wander into great absurdities on the other, was born at Arezzo in Tuscany in 1519. Of his family nothing is recorded, nor does he appear to have left any progeny, or to have been ever married. Devoted to the studies of physic and natural philosophy, he attained at length the honour of being physician to Pope Clement VIII., during the chief part of whose pontificate, from 1592 till his own death in 1603, at the age of eighty-four, Cæsalpinus lived at Rome, in the highest credit and celebrity; for which, as we trace the circumstances of his history, and inquire into his opinions, it seems at first sight difficult to account. Eminent talents have seldom proved a shield against persecution. On the contrary, by adding fear to its malice, they have generally tended to exasperate its fury. How then could Cæsalpinus, a professed Aristotelian, and an open unbeliever of revealed religion, whose opinions nearly approached those of Spinosa, exist in the holy court of Rome, which was then beginning to persecute the immortal Galileo? This mystery will but too readily unravel itself.

Cæsalpinus seems to have been furnished with two distinct philosophical intellects, which, like a good and evil genius, directed him by turns. Under the influence of the one he discovered the circulation of the blood, the sexes of plants, and the only true principles of botanical classification; under the guidance of the other he became entangled in the metaphysics of the schools, the dreams of Aristotle, and a philosophic contempt for every thing, good or bad, connected with the nonsense he was obliged publicly to respect. It is scarcely necessary to remind the reader, that, however brilliant the reign of literature and taste in the golden age of Leo X. and the times which immediately succeeded, true science and experimental philosophy were as yet in the cradle. In this respect the time of Cæsalpinus was "dark as Erebus," and the light he struck out was altogether his own.

We have no account of this great man till we find him seated in the botanical chair of the University of Pisa, where also he studied, if he did not teach, anatomy and medicine. His first publication was entitled *Speculum Artis Medicæ Hypocraticum*, in which it were too much to expect he should have released himself from the shackles of his venerable guide; but he has left evident proofs, in a passage often quoted, of his having a clear idea of the circulation of the blood, at least through the lungs. In botany his inquiries were conducted on a more original plan, and their result was one of the most philosophical works in that science, which issued from the press at Florence in 1583, in one volume quarto. The title-page runs thus: *De Plantis libri XVI. Andreæ Cæsalpini Aretini, Medici clarissimi doctissimique, atque Philosophi celeberrimi ac subtilissimi;* yet he appears to have been himself the editor of the work, to which is prefixed, in his own name, an elegant and learned epistle dedicatory to Francis de' Medici, grand duke of Tuscany. This book, now rarely to be met with, is not only the unacknowledged source from which various subsequent writers, and especially Morison, derived their ideas of botanical arrangement; but it was a mine of science to which Linnæus himself gratefully avowed his obligations. His own copy evinces the great assiduity with which he studied the book. He has laboured throughout to remedy the defect of which Haller complains, of the want of synonyms; and has subjoined his own generic names to nearly every species. He has particularly indicated those remarkable passages, in pages 13 and 15, where the germination of plants and their sexual distinctions are explained. In the former we trace the first rudiments of a natural classification of plants by the differences in their cotyledons; or, in other words, we find the origin of the natural systems of Linnæus and Jussieu: in the latter passage we detect the fundamental principle of the Linnæan artificial system. Nor were these merely incidental suggestions of the illustrious author. He has pursued his inquiries to a conclusion on which the existence of botany as a science depends, and which the no less eminent Conrad Gesner detected about the same time, though his ideas respecting it were not then made public. The principle to which we allude is the classification of plants by their parts of fructification alone. This was afterwards extended, by the greatest writers on the subject, as Ray and Tournefort, and more completely by Linnæus, to the discrimination of their genera by the same parts, more particularly considered and contrasted. To this more extensive conclusion, indeed, the principle of Cæsalpinus directly and inevitably leads. He pursued it himself to such a length, as to develop some of the most important characters for generic distinctions, such as the flower being superior or inferior with respect to the fruit; the heart of the seed situated at its summit or base; the seeds, or the cells of the seed-vessels, solitary or otherwise; the partitions of certain pericarps parallel or contrary to their valves. Linnæus remarks that this author, though the first systematical botanist, found out as many natural classes, or orders, as any of his followers. He did not indeed define well the philosophical limits of genera in the vegetable kingdom, and therefore his work cannot be regularly quoted throughout for generic synonyms. The want of plates of his own, and of references to other authors, render, as we have already hinted, some of his names and descriptions unintelligible. Yet Linnæus has in manuscript filled up many blanks which he had been obliged to leave in his own *Classes Plantarum*, where the system of Cæsalpinus first assumed a synoptical form. This author might probably have adopted a more clear and methodical mode of arranging and explaining the botanical part of his subject, had he not had in view the vague and desultory manner of Pliny, whom he closely imitates in the materials of his numerous chapters, as well as in his style of description. A small and unimportant *Appendix* to this work, of nineteen pages, appeared at Rome in 1603, which is of very rare occurrence, but may be found reprinted in Boccone's *Museo di Piante Rare*, p. 125.

Cæsalpinus printed at Rome, in 1596, a quarto volume of above two hundred pages, entitled *De Metallicis*, dedicated to Pope Clement VIII. which, like his botanical publications, is now extremely rare. In the philosophy of this work Aristotle is his guide; in its method and composition, Pliny. A prefatory address to the pope declares it to have been undertaken in opposition to a certain treatise on the same subject, which, though written with diligence and elegance, contained many things inconsistent with the principles of philosophy, and subversive of the peripatetic doctrines; and with the author of which, as being excommunicated by the holy church of Rome, no measures were to be kept.

In our author's *Quæstionum Peripateticarum libri quinque*, published at Rome in 1603, it appears that he scrupled not to stand forth as an open defender of the Aristotelian philosophy, without any concealment of his own peculiar opinions and hypotheses derived from thence. By these he incurred the charge of atheism, preferred by a physician

Cæsalpinus.

named Taurel, who, punning on the name of his antagonist, entitled his book *Alpes cæsæ, hoc est, Andreæ Cæsalpini monstrosa dogmata discussa et excussa*. This attack, however, met with little or no countenance; and the learned Aristotelian died in the course of the year, receiving, no doubt, in the very focus of sanctity itself, the funeral honours due to an orthodox physician of his holiness.

Of the medical publications of Cæsalpinus, entitled *Praxis Universæ Medicinæ*, and *De Medicamentorum Facultatibus*, we have had no opportunity of forming an opinion for ourselves. By what is to be gathered from his other writings, his ideas of the medical qualities of plants and fossils seem adopted from ancient writers rather than from any considerable portion of actual experiment. Like other physicians of his time, he was too much occupied in ascertaining the articles of the *materia medica*, to find leisure for doubt, or for practical inquiry, respecting the truth of their reputed virtues. He did, however, promulgate some original ideas relative to the investigation of the properties of plants by their taste and smell. With botany he was not only theoretically but practically conversant. He left behind him a collection of above 760 dried specimens, one of the earliest upon record, which is said to have come into the hands of Micheli, and therefore is doubtless still preserved in the museum of Dr Targioni Tozzetti at Florence. A catalogue of this venerable herbarium is reported to have been prepared for the press, but we do not find that it ever appeared.

Cæsalpinus having been settled at Pisa when the great Galileo first presumed to doubt the infallibility of the Aristotelian philosophy, and, most likely, when that rising character became, at the age of twenty-six, professor of mathematics in the same university, we cannot presume him to have been free from the party-spirit which so disgracefully manifested itself there. He must have concurred in the measures which his own associates, leagued with the ruling powers, thought proper to adopt. The ancient school philosophy, derived from the Peripatetics, whether it was considered as a mere abstract speculation, or whether, as being equally absurd and unintelligible with the orthodox establishment, it did not excite alarm, was, as every body knows, allowed to go on very lovingly with that establishment; nor did it, in general, raise any more suspicion than the heathen mythology, studied and exemplified in the same and other schools. But when a spirit of truth and inquiry arose, when principles and opinions were to be submitted to the tests of reason and experiment, the same fatal results which the preceding age had witnessed in what was called religion, were justly apprehended for what was now with scarcely more propriety denominated philosophy. Hence the papal authority, which had suffered shipwreck in the one case, wanting the wisdom to avoid a similar disgrace in the other, gladly clung for support to any ally. These two celebrated occasions, the divorce of Henry VIII. and the base persecution of Galileo, are almost the only ones in which the authority of the pope has been exerted about any matter that human reason could determine, or that much signified, except to his own immediate dependents, how it might be determined. It is a memorable fact, that his decision was no less just in one case than unjust in the other; yet both proved equally ruinous, the former to his power, the latter to his credit. So hazardous is the exercise of usurped or overstrained authority, and so infallibly, thanks to the Author of all Good, do truth and justice rise, with renovated vigour, from such contests.

By this view of our subject the mystery above alluded to becomes clearly unravelled. Cæsalpinus, though a known heretic and infidel, professing to be an obedient son, and even a champion, of the church, tried to rise by the ruin of equally learned and more honest men than himself. On the side on which he was absurd and censurable, and on that side only, he was unjust and unprincipled; nor is such a character uncommon. Where he exercised his unbiassed judgment, and honestly sought for truth, he, like Galileo, enlarged the bounds of human knowledge, and made discoveries which will for ever claim the gratitude and admiration of mankind. (J. E. S.)

Cæsar.

CÆSAR, C. Julius, the illustrious Roman general and military historian, was the son of C. Julius Cæsar, who held the office of prætor, and of Aurelia, who is conjectured to have been the daughter of M. Aurelius Cotta. He was born July 12 B.C. 100, and was thus six years younger than Cicero and Pompey. His aunt had married the great Marius; and through the influence of this powerful connection, he was raised to the dignity of flamen dialis while still in his thirteenth year. Not long afterwards he married Cossutia, a lady of good family, with whom he received a large fortune; but before he had completed his seventeenth year he divorced her, and took to wife the daughter of Cornelius Cinna, one of the leaders of the popular party. This marriage drew down upon him the anger of Sulla, who ordered him to put away his young wife. Cæsar refused, and was immediately proscribed, losing at the same time his office and his fortune. Though his life was spared, it was not till after the death of Sulla that he began to take a prominent part in public affairs. He first became famous as an orator, and it is agreed that if he had confined himself solely to oratory, he would have taken rank among the best speakers of Rome. His powers of persuasion were always employed in the cause of the people, with whom he spared no effort to ingratiate himself. His popularity soon became unbounded, and from this time till his death his career was uniformly progressive. He obtained in rapid succession the highest civil and military honours that his country had to bestow; and having defeated his rival Pompey on the plains of Pharsalia B.C. 48, he remained undisputed master of the whole Roman empire. He caused himself to be chosen perpetual dictator, and had actually consented to accept the imperial crown, when he was murdered by the remnant of the republican party, who hoped by his death to restore the old constitution. He fell in the senate-house on the 15th of March B.C. 44. Cæsar wrote many works, the majority of which have been lost, but their titles, which have been preserved, are proofs of his great mental activity and varied accomplishments. The purity of his diction and the clearness of his style were acknowledged by the ancients themselves, whose testimony is amply confirmed by the *Commentarii*, which have descended to us entire. In this work is given a detailed history of the first seven years of the Gallic war, and of the first three of the civil war. The best editions of this work are those of Jungermann (with the Greek translation of Planudes), Frankf., 1606 and 1669; of Grævius, Amsterdam, 1697; of Davis, Cambridge, 1706; of Oudendorp, Leyden, 1737; and of Morus, Leipzig, 1780. The history of this illustrious man is given in detail under the head Roman History.

Cæsar, in *Roman Antiquity*, a title borne by all the emperors, from the time of Julius Cæsar till the destruction of the empire. It was also used as a title of distinction for the intended or presumptive heir of the empire; as *King of the Romans* was latterly used for that of the German empire.

This title took its rise from the surname of C. Julius Cæsar, which, by a decree of the senate, all the succeeding emperors were to bear. Under his successor, the appellation of *Augustus* being appropriated to the emperors in compliment to the prince of that name, the title *Cæsar* was given to the second person in the empire, though still it continued to be used by the first; and hence the difference between Cæsar used simply, and Cæsar with the addition of Imperator Augustus.

The title of Cæsar was allotted to the second personage of the empire, till Alexius Comnenus found it necessary, in consequence of having elected Nicephorus Melissenus Cæsar by contract, to confer some higher dignity on his own brother Isaacus. He created him Sebastocrator, with the precedency over Melissenus; ordering that in all proclamations Isaacus Sebastocrator should be named the second, and Melissenus Cæsar the third.

CÆSAR, *Sir Julius*, a learned civilian, was descended by the female line from the Dukes de' Cessarini in Italy, and was born near Tottenham in Middlesex in the year 1557. He was educated at Oxford, and afterwards studied in the university of Paris, where in the year 1581 he was created doctor of the civil law. Two years afterwards he was admitted to the same degree at Oxford, and also became doctor of the canon law. He was advanced to many honourable employments, and for the last twenty years of his life was master of the rolls. Sir Julius was remarkable for his bounty and charity to all persons of worth, so that he seemed to be the almoner-general of the nation. He died in 1639, in the seventy-ninth year of his age. It is worthy of notice that the manuscripts of this lawyer were offered by the executors of some of his descendants to a cheesemonger as waste paper; but their value having accidentally been discovered they were sold by auction in 1757 for upwards of L.500. Many of these MSS. are now in the British Museum.

CÆSAREA, two towns in Palestine. (1.) CÆSAREA PALESTINA, or CÆSAREA, the Roman metropolis of Palestine, lies 35 miles north of Joppa and 55 miles from Jerusalem. It was built about B.C. 22 by Herod, who also adorned it with many splendid buildings, among which was a temple dedicated to Cæsar, a theatre, and an amphitheatre. His most stupendous work, however, was the semicircular mole, constructed of immense blocks of stone brought from a great distance, and sunk to the depth of twenty fathoms in the sea. It protected the port on the south and west, leaving only a sufficient opening for vessels to enter from the north, so that within the inclosed space a fleet might ride at all weathers in perfect security. Its site is now marked by an extensive mass of ruins, among which may be seen those of an old castle, two aqueducts, &c. Its only inhabitants now are snakes, scorpions, lizards, wild boars, and jackals. (2.) CÆSAREA PHILIPPI lay 120 miles north of Jerusalem, and a day and a half's journey from Damascus. It was much enlarged and beautified by Philip the Tetrarch, who named it Cæsarea in honour of Tiberius the emperor, adding the cognomen of Philippi to distinguish it from the preceding. Its site is occupied by the modern Bâniâs, a paltry and insignificant village, with numerous ruins in the vicinity. There were several other places of this name.

CÆSAREAN OPERATION, the extraction of a child from the womb by a surgical operation. It is said that in this way Julius Cæsar was brought into the world.

CÆSONES, a denomination given to those cut out of their mother's wombs. Pliny ranks this as an auspicious kind of birth.

CÆSTUS, or CESTUS, in *Antiquity*, a gauntlet made of thongs of raw hide or leather, which was worn by the pugilists in the public games. The cæstus encompassed the hand, wrist, and part of the arm; and in later times it was loaded with lead or iron, in order to give greater effect to the blows.

CÆSTUS also denoted the girdle of Venus. See CESTUS.

CÆSURA (Latin *cædo*, I cut) is the name given to the division of certain of the longer kinds of verse into two parts, by causing a word in a given position to end in the middle of a foot, as in the pentameter. The term *cæsura* is also applied to a division of words at the termination of each foot, and according to its position in the line is called *triemimeral, penthemimeral, hephthemimeral,* or *ennehemimeral, i. e.* occurring at the 3d, 5th, 7th, or 9th half foot. It seldom happens that all these cæsuras are met with in the same line. In the following verse the first three of them occur—

Una sa-lus vic-tis nul-lam sper-are sa-lutem.

Though the cæsura may happen to be a short syllable, it is frequently lengthened both by the Greek and Latin poets.

CÆSURA, in modern poetry, denotes a rest or pause so introduced as to aid the recital, and render the versification more melodious. It divides a verse or line into equal or unequal parts.

CÆTERIS PARIBUS, a Latin term in frequent use among mathematical and physical writers. The words literally signify *other things being alike or equal.* Thus we say, the heavier the bullet, *cæteris paribus,* the greater the range; that is, by how much the bullet is heavier, if the length and diameter of the piece and strength of the powder be the same, by so much will the utmost range or distance of a piece of ordnance be the greater. Thus also we say, the velocity and quantity circulating in a given time through any section of an artery will, *cæteris paribus,* be according to its diameter, and nearness to or distance from the heart.

CAFFA. See KAFFA.

CAFFEINE, the stimulant principle in coffee, was discovered by Runge in 1820. He obtained it by precipitating a cold infusion of coffee by acetate of lead, and throwing down the lead by sulphuretted hydrogen. It was obtained in colourless acicular crystals. It contains 21·6 per cent. of nitrogen, a larger quantity of that gas than is yielded by any other organic compound except urea and uric acid. Caffeine is identical in composition with *theine.* See CHEMISTRY.

CAFFILA, a kind of caravan or company of merchants. It differs, however, from a caravan, at least in Persia; for the caffila properly belongs to some sovereign, or to some powerful company in Europe; whereas a caravan is a company of particular merchants, each trading upon his own account. Caffilas also cross some parts of the deserts of Africa, particularly that of Sahara.

CAFFRARIA, See AFRICA and KAFFRARIA.

CAFTAN, a Persian and Turkish vest or garment.

CAGANUS, or CACANUS, an appellation anciently given by the Huns to their kings. It appears also to have been formerly applied to the princes of Muscovy, now called *czar.* From the same root also was probably derived the Tartar title *cham* or *khan.*

CAGE, an inclosure made of wire, wicker, or the like, interwoven lattice-wise, for the confinement of birds or wild beasts. The word is French, *cage,* formed from the Italian *gaggia,* of the Latin *cavea,* which has the same signification: *a caveis theatralibus in quibus includebantur feræ.*

In the ancient amphitheatres, the fiercer animals were put in dens under ground, or in iron cages called *caveæ,* ready to be let out for sport.

In some prisons there are iron cages for the closer confinement of prisoners. History affords various instances of persons subjected for a series of years to this cruel species of confinement.

CAGLI (the ancient *Callis*), a walled town of Italy, States of the Church, in the legation and 14 miles south of Urbino, at the confluence of the Cantiana and Busso. It is the seat of a bishop, and has a cathedral with several churches and monasteries. Pop. 5000.

CAGLIARI, a province of Sardinia, embracing the extreme southern part of the island; bounded N. by Isili, N.E. by Lanusci, W. by Iglesias. Pop. (1848) 106,388.

CAGLIARI, the capital of the above province, and of the island of Sardinia, situated in the recess of the bay of Cagliari, on the southern coast of the island, in N. Lat. 39. 33. 14., E. Long. 9. 7. 48. It is built on the slope of a hill, the summit of which is crowned by a noble castle, containing the vice-regal palace, the cathedral, the university, and public seminaries. The intermediate slope between the bay and the district of the castle is occupied by the Marina, a well-built

quarter, where the merchants and consuls reside. Lining the coast are the warehouses, the lazaretto, and the mole. To the west of the castle stands the district of Stampace, to the east that of Villanova,—both consisting of narrow, irregular, and ill-paved streets,—while outside is the spacious suburb of St Avandres, nearly a mile in length. The principal public buildings are those in the castle, including the cathedral already mentioned, built by the Pisans during their occupation of the island, with a handsome front mostly of marble; the vice-regal palace; the mausoleum of Martin, king of Sicily; and the citadel on the northern side, surmounted by three square Pisan towers. The educational and literary establishments of Cagliari include the university (with the four faculties of theology, law, medicine, and philosophy, and enrolling from 200 to 300 students), a private college for the nobility, museums of antiquities and natural history, and a public library containing 15,000 vols. Besides the cathedral, Cagliari contains about 30 churches and 21 convents, to one of which is attached a handsome chapel. It is the see of an archbishop, and the seat of the cortes or states-general for the whole island, and of the audienza or judicial court for the southern division. The bay of Cagliari contributes greatly to its commercial importance. It is formed by the projection of Cape Carbonara on the one side and Pula on the other; having an extreme width of 24 miles, and a depth of 12. The harbour at the south angle of the wall of the Marina quarter, inclosed by a projecting pier, is one of the best and safest in the Mediterranean, being well sheltered from every wind except the south. Cagliari is the chief port of Sardinia, and monopolizes almost all the export trade of the island. The exports consist chiefly of the corn, oil, wine, and manufactures of the country. The principal articles of manufacture are tobacco (which is a royal monopoly), cotton fabrics, soap, chairs, and salt; the last article being procured from numerous salterns in the bay of Cagliari and the neighbourhood.

From the elevation of its site the climate of Cagliari is healthy, notwithstanding its immediate proximity to a stagnant swamp six or seven miles in length. Pop. nearly 28,000.

The modern city stands on the site of the ancient Carales, or Caralis, which was founded by the Carthaginians, but passed into the hands of the Romans after the first Punic war. In the civil wars between Cæsar and Pompey, and during the empire, it was regarded as an important naval station, but was never raised to the status of a Roman colony. After the fall of the Western Empire it continued under the Vandals to be the capital of the island, and retained its importance during the middle ages. The site of the ancient city is still marked by the remains of a large aqueduct, a circular temple, and numerous Roman sepulchres.

Cagliari, *Paolo*, called *Veronese*, a distinguished painter, born at Verona in 1532. His father Gabriele Cagliari, who was a sculptor, perceiving his son's extraordinary predilection for painting, placed him with his uncle Badile, then one of the most eminent artists at Verona. Here he rapidly distinguished himself; and while still a mere youth, was employed by Cardinal Ercole Gonzaga to paint an altarpiece for the cathedral of Mantua. Proceeding afterwards to Venice, he was engaged to paint the ceiling of the church of St Sebastian in that city, and produced his celebrated work, the story of Esther, which at once established his fame. In conjunction with Tintoret, F. Bassano, and Battista Franco, he was employed to execute some works for the senate, and bore away the palm of victory,—an honour that was enhanced by the circumstance that Titian and Sansovino were the judges. He visited Rome in the suit of Grimani the Venetian ambassador; and while there he made the works of Michael Angelo and Raphael the especial objects of his study. Yet it must be observed that Paul Veronese was guided solely by the impulses of his own genius and vivid imagination, which delighted in gorgeous effect and magnificence of costume, even where such accessories were out of place,—a peculiarity that is manifest in his great picture of the Marriage at Cana, in which the guests are represented in the rich attire of the luxurious Venetian nobility of his time. He was esteemed the greatest of the Lombard school, and was not inappropriately styled *Il pittore felice.* At Venice the specimens of this great master are very numerous. His principal works are the following: *The Marriage at Cana* (in which he has introduced at least 150 heads), now in the Louvre; *The Feast of Simon*, with Mary Magdalene washing our Saviour's feet,—painted for the church of St Sebastian; *Christ at Table with his Disciples*, —painted for the church of SS. Giovanni e Paolo; *The Feast of Simon*, differently painted from that above mentioned,—presented by the republic, in 1665, to Louis XIV.

This great painter died at Venice in 1588; and a statue of brass was erected to his memory in the church of St Sebastian. (See Lanzi, *Storia Pittorini.*)

CAGLIOSTRO, Alessandro, *Count*, the arch-impostor of modern times, was born at Palermo in 1743. Joseph Balsamo—for such was the count's real name—gave early indications of those talents which afterwards gained for him so wide a notoriety. He received the rudiments of his education at the convent of Cartagirone; where, being employed to read to the monks during dinner, he scandalized the good fathers by repeating the names and detailing the adventures of the most notoriously profligate females of his native town. For these and similar misdeeds he was expelled from the convent and disowned by his relations. He now signalized himself by the ingenuity with which he contrived to perpetrate his crimes without exposing himself to the risk of detection. He began by forging tickets for the theatres, then he forged a will; he next robbed his own uncle, and ultimately committed a murder. For this latter offence he was imprisoned and brought to trial, but through a defect in the evidence escaped with his life. On his release he engaged a goldsmith, by name Marano, to assist him in searching for a hidden treasure; the said Marano paying 60 ounces of gold in advance to defray expenses. On arriving at the cave, where Joseph declared the treasure to be, six devils prepared beforehand rushed out upon the goldsmith, beat him soundly, and left him insensible. Dreading the vengeance of Marano, Balsamo quitted Sicily, and visited in succession Greece, Egypt, Arabia, Persia, Rhodes (where he took lessons in alchemy and the cognate sciences from the Greek Althotas), Malta, Naples, Rome, and Venice. At Rome he married a beautiful but unprincipled woman, with whom he travelled under a variety of names through the various countries of Europe. It is unnecessary to recount the various infamous means which he employed to support himself during his travels. At Strasbourg he reaped an abundant harvest by professing the art of making old people young; in which pretension he was seconded by his wife, who, though only twenty years of age, declared that she was sixty, and that she had a son a veteran in the Dutch service. In Paris he was implicated in the affair of the diamond necklace; and though he escaped conviction by the matchless impudence of his defence, he was imprisoned for other reasons in the Bastile. On his liberation he visited England, where he succeeded well at first, but was ultimately overreached by some English lawyers, and confined for a while in the Fleet. He then left the ungrateful country, and travelled through Europe till he arrived at Rome, where he was arrested in 1789. He was tried and condemned to death for being a freemason, but the sentence was afterwards commuted to perpetual imprisonment. He died in the fortress-prison of San Leo in 1795. For a detailed account of the life, adventures, and character of Joseph Balsamo, see Carlyle's *Miscellanies*, and Dumas' *Memoirs of a Physician.*

CAHER, or Cahir, a market-town in Tipperary, Ireland, on the river Suir, 96 miles S.S.W. from Dublin. It

contains a handsome parish church, a Roman Catholic chapel, and a meeting-house of the Society of Friends. There is also a market-house, a fever hospital, several public schools, a police-station house, and large cavalry barracks. In the neighbourhood, on an island on the Suir, is Cahir Castle, the residence of the Earl of Glengall. The trade of the town arises chiefly from the flour-mills in the neighbourhood, although repeated attempts have been made to introduce the manufacture of linen and straw-plait. There is a weekly corn-market in Cahir, and fairs are held seven times a-year. Pop. (1851) 3719.

CAHORS, a town in the south of France, capital of the department of the Lot, on the high road between Paris and Toulouse, 358 miles S.W. from Paris, and 60 miles north of Toulouse. N. Lat. 44. 27., E. Long. 1. 24. It stands on the right bank of the river Lot, on a rocky peninsula formed by a bend in the stream, and communicates with the opposite shore by three bridges; one, which is the Pont Valendré, built in the thirteenth century, and surmounted by three massive towers. In the more ancient part of the town the streets are narrow and the houses antique; but in the modern and more elevated quarter there are many handsome buildings, with terraces which command an extensive view. The most remarkable building is the cathedral, occupying the site, if not actually consisting of the remains, of an ancient Roman temple, with recent additions in the Gothic and Byzantine styles. Besides it, there is the theological seminary; the hotel of the prefecture, formerly an episcopal palace; a theatre, a public library, and a monument erected to Fenelon in front of the university, of which he was a student. Cahors is the see of a bishop, and the seat of judicial and commercial tribunals of the first class. Its educational establishments comprise a royal college, a diocesan seminary, and a primary school. The principal articles of manufacture are stoneware, cotton-yarn, woollen stuffs, and paper; and it has a considerable traffic in oil, hemp, flax, hides, truffles, and a strong deeply-coloured wine which is made in the neighbouring districts. Pop. (1851) 12,103. The population of the arrondissement of the same name in 1851 was 118,515.

Cahors is the ancient Divona, afterwards called Civitas Cadurcorum from the Celtic tribe whose capital it was, and still exhibits traces of its greatness during the Roman sway. The most conspicuous remains are those of an immense aqueduct, which conveyed the water to the city from a distance of about 19 miles by a precipitous route along the mountain-sides, and crossed the valley of Larroque-des-arcs on a bridge 180 feet high. There are also remains of baths, a theatre, a marble altar, erected, according to the inscription, in honour of Lucterius Leo, and a celebrated fountain supposed to be the fountain Divona (the fountain of the goddess), and now called Des Chartreux, from the Carthusian convent to which it has been attached.

CAIAPHAS, high priest of the Jews, was the successor of Simon. He condemned our Saviour to death. What became of Caiaphas after he was deposed (A.D. 38), is not known.

CAILLE, Nicolas Louis de la, a celebrated French astronomer, born at Rumigny in the department of Aisne, March 15, 1713. His father was a gentleman in easy circumstances, who devoted the greater part of his time to the study of philosophy and natural science, and early succeeded in inspiring his son with similar tastes. On the death of this parent the young La Caille found himself entirely destitute. He was soon enabled, however, to resume his studies by the generous interposition of the Duke of Bourbon. His first intention was to enter the church, but he speedily abandoned his theological studies, and devoted himself to the physical sciences, especially astronomy. On his arrival at Paris he was cordially welcomed by Cassini, who gave him an apartment in the observatory. He here gained the friendship of Maraldi, whom he helped to take the bearings of the French coast from Nantes to Bayonne. Such was the ability he displayed on this occasion, that he was employed to assist in the verification of the French meridian. This gave him an opportunity of correcting the measurements of Picard, taken in 1669. While absent on this mission, he was appointed professor of mathematics in the Mazarin college. His calculations completed, he proved by a comparison of the different arcs which he had measured that degrees go on increasing from the equator to the pole; a proposition familiar to every one now, but at that time directly opposed to the results of previous researches. After taking possession of his professorial chair he published successively *Leçons élémentaires de Mathématiques*, 1741; *Leçons de Mécanique*, 1743; *Leçons d'Astronomie*, 1746, re-edited by Lalande in 1780; *Eléments d'Optique*, 1750. He also calculated the eclipses for 1800 years for the first edition of the work entitled *L'art de vérifier les dates*.

Being curious to determine and verify the stars of the southern hemisphere, he undertook a voyage to the Cape of Good Hope, where in 127 nights he calculated the positions of 10,000 stars, with a quickness and correctness, says Delambre, that would have been deemed impossible, considering the deficient means at his disposal. He likewise determined at the Cape the parallax of the moon, and of the planets Mars and Venus, and measured a degree of the southern hemisphere. While engaged in these duties, he received orders from the French government to survey the islands of Bourbon and Mauritius, and determine their positions. During these various voyages he devoted much of his time to the problem of longitudes, on which subject he had a controversy with the German Euler on his return to Paris in 1754. To escape the public curiosity, he shut himself up in his observatory, dividing his time between his calculations and his duties of professor and academician. In 1757 he published his *Astronomiæ fundamenta*, and in the following year his *Tables Solaires*. He soon after published the *Traité de la gradation de la lumière*, of which Bouguer had bequeathed him the manuscript at his death, and brought out a new edition of the *Traité de la Navigation* by the same author. In the midst of his multifarious labours, he was surprised by a violent attack of the gout. Feeling his illness increase, and that he had no prospect of recovery, he gave back all the instruments that he had borrowed from his friends, and died March 21, 1762, leaving his MSS. to Maraldi, who published the *Cœlum Australe Stelliferum* in the year after the author's death. It was said of La Caille by Lalande, that he made more observations and calculations than all the astronomers of his time put together.

CAIMACAN, or Kaimacam, a dignity in the Ottoman empire, answering to lieutenant, or rather deputy, amongst us. There are usually two caimacans, one residing at Constantinople as the governor; the other attending the grand vizir in quality of lieutenant; and sometimes there is a third caimacan. Among the Tartars of the Crimea, the caimacan acts as the deputy of the khan during his absence.

CAIN, eldest son of Adam and Eve, killed his brother Abel, for which he was condemned by God to banishment and a vagabond state of life. Cain retired to the land of Nod on the east of Eden, and built a city, to which he gave the name of his son Enoch.

CAINITES, a sect of heretics in the second century, so called from their respect for Cain. They pretended that the virtue which produced Abel was of an order inferior to that which had produced Cain, and that this was the reason why Cain overcame Abel; for they admitted a great number of genii, or virtues, of different ranks and orders. They honoured those who carry in Scripture the most visible marks of reprobation, as Esau, Korah, Dathan, Abiram, and the inhabitants of Sodom. They particularly venerated the traitor Judas, on the ground that the death of Christ had saved mankind. They had also a forged gospel of Judas.

CAIRN, (in Welsh *Carne*), the name given to those ancient heaps of stones found in Scotland and Wales, generally of a conical form, and surmounted by a flat stone. They appear to have been used as sepulchral monuments, to commemorate great events, and perhaps also in connection with religious rites. See BARROW.

CAIRNGORM. See ABERDEENSHIRE.

CAIRNGORM, a yellow or brown variety of rock-crystal or crystallized silica, from the mountain Cairngorm in Scotland.

CAIRO, the modern capital of Egypt, occupies the natural centre of the country, situate on the east bank of the Nile, 12 miles above the apex of its delta, 112 miles S.E. of Alexandria, and 75 miles west from Suez. N. Lat. 30. 2. 4.; E. Long. 31. 15. 36. It is built partly on the plain and partly on the lower slopes of the rocky range of Mokattem, on a spur of which stands the citadel, in a most advantageous position to command the town.

Cairo occupies a site of about 7 miles in circumference, and is surrounded by a wall strongly built and fortified with lofty towers. The prospect from the ramparts of the citadel is one of great magnificence and beauty. Below lies the city, its gardens, squares, palaces, and mosques, in all the beauty of their delicately carved domes, and minarets covered with fantastic tracery,—the port of Bulâk,—the gardens and palace of Shubra,—the broad river studded with islands,—the valley of the Nile dotted with groups of trees,—with the pyramids on the north horizon,—the fields, gardens, and villas on the west,—and on the east the barren cliffs, backed by an ocean of sand. The interior of the city, however, is far from presenting so pleasant an aspect. It is little better than a labyrinth of tortuous lanes, narrow, unpaved, and continually swept with clouds of dust blown from huge mounds of rubbish outside the walls. The most of the houses of the poorer classes consist of miserable mud hovels, with filthy courts, dilapidated windows, and tattered awnings. In marked contrast to these are the houses of the wealthier citizens, built generally in a style of elaborate arabesque, the windows shaded with projecting cornices of graceful woodwork, and ornamented with stained glass. A winding passage leads through the ornamented doorway into the court, in the centre of which is a fountain shaded with palm-trees. The principal apartment is generally paved with marble; in the centre a decorated lantern is suspended over a fountain, whilst round the sides are richly inlaid cabinets, and windows of stained glass; and in a recess is the *divan*, a low narrow cushioned seat running round the walls. The basement story is generally built of the soft calcareous stone of the neighbouring hills, and the upper story, which contains the harem, of painted brick. The town is walled off into quarters, deriving their names from the character or condition of their occupants, and is intersected in its whole breadth by a canal which conveys the waters of the Nile from Old Cairo to the different parts of the city. The most prominent object in Cairo is the citadel, standing on an eminence 250 feet above the level of the town. It contains the pasha's palace, a mosque of oriental alabaster built on the site of Joseph's Hall, and the pasha's harem. In the centre is a famous well called Joseph's well, sunk in the solid rock to the level of the Nile—a work generally attributed to Saladin. The citadel also contains an arsenal, a cannon foundry, and a manufactory of fire-arms. Next to the citadel in importance are the mosques, 400 in number, including, however, many that are falling to ruins. The most magnificent is the mosque of Sultan Hasan, standing in the immediate vicinity to the fort, celebrated for the grandeur of its porch and cornice, and the delicate honeycomb tracery which adorns them. Besides it there is the mosque of Tulun (founded A.D. 879), exhibiting very ancient specimens of the pointed arch; the mosque of Sultan el Hakem, the fanatical patron of the Druzes, founded A.D. 1003; the mosque of Ezher, the seat of the Mohammedan college where gratuitous instruction is given in the Koran, and where a number of blind paupers find a secure asylum. Attached to the mosque of Sultan Kalaoon is the Morostan or asylum for the insane. But the highest style of architectural magnificence is to be seen in the tombs, which are mostly outside the walls. On the east are what are known to Europeans as the tombs of the caliphs, although the graves of the Abbasides and Ommiades are not to be found in Egypt. They are the tombs of the Circassian or Borgite mamelukes—a race extinguished by Mehemet Ali. Their lofty gilt domes and fanciful network of arabesque tracery are fast falling to ruins, and the mosques attached to them are the haunts of a few solitary sheikhs, and of hordes of Arab beggars.

The gates of Cairo are built in the prevailing Saracenic style, round-headed, with cornices and towers. The principal square in the city is the Uzbekeeh, once covered by the Nile, but now drained and planted. Emerging from this square we come to Bulâk, the port of Cairo, formerly an island, but now joined to the bank of the river. In it are several of the pasha's factories for spinning, weaving, dyeing and printing cotton, for casting and making arms. Here too is the government printing-press established by the late pasha, from which there have issued many oriental and numerous translations of French scientific works.

Three miles south of Cairo stands the Coptic village Musr el Ateekeh, originally called Fostat, or Old Cairo. It occupies part of the site of the ancient Egyptian Babylon, and still gives indications, from the style of its masonry and the character of its ruins, of having been a Roman station. It contains the celebrated depot called Joseph's granary, still used as a storehouse for the troops, and the mosque of Amer. Opposite it is the beautiful island of Rhoda and the Nilometer. Four miles north of Bulâk, and about the same distance from Cairo, stands the palace of Shubra, a pile of low narrow buildings, deeply imbedded in groups of walnut, orange, and cypress trees.

Except public buildings there is very little worthy of special notice in Cairo. The scheme of public instruction here, as in Alexandria, is that which was organized by the late pasha, and embraces primary, preparatory, and polytechnic schools. During the lifetime of Mehemet Ali, their founder, there were no fewer than 800 pupils attending the four primary and 1500 attending the two preparatory schools of Cairo; but as this result was obtained partly by compulsion and partly by bribery, it remains to be seen whether or not from the violence of the effort it will not be followed by a powerful reaction.

The commerce of Cairo, although still depressed, is considerable. Being the rendezvous of one of the great caravans to Mecca, it is still the centre in which the slaves, gum, and gold-dust of the interior, and the oils and flannels of the north of Africa, with the European merchandise from Alexandria, are exchanged for the coffee, perfumes, spices, and shawls of Arabia and India. As the residence of the learned and wealthy of Egypt, it affords a market for the agricultural produce of the surrounding districts; and in addition to the making of arms already alluded to, it contains manufactories of sal-ammoniac, saltpetre, coarse gunpowder, glass lamps, and linen cloths.

From the central situation of Cairo, and its proximity to the hot sandy deserts, its temperature is much higher than near the coast; but the diseases which infest it, such as the plague, ophthalmia, and malignant fevers, seem to originate in its "stifled filth," and other local causes which advancing civilization will greatly remove, rather than in the unhealthiness of its situation. Pop. estimated at about 200,000, comprising about 121,000 Mohammedans, 60,000 Copts, 4000 Jews, and the rest Franks, Greeks, and Armenians.

Cairo is said to have been founded by El-Moez, the first of the Fatemite rulers of Egypt, about A.D. 969. It was partly burnt in 1171 by the Saracens, to check the progress of the invaders, but was rebuilt by Saladin, and shared the fortunes of the various Egyptian dynasties, till it fell into the hands of the Turkish Selim I. in 1517. It was nearly destroyed by an earthquake in 1754. It was taken by the French in 1798, but retaken by the British in 1801.

CAISSON (from the French *caisse*, a chest), in the military art, a wooden chest, into which several bombs are put, and sometimes gunpowder only. This is buried under some work of which the enemy intend to possess themselves, and fired when they have got possession.

CAISSON also denotes a wooden frame or chest used in laying the foundations of the piers of a bridge.

CAISTOR, a market-town and parish in Lincolnshire, 20 miles N.N.E. of Lincoln, and 153 miles from London, It was called by the Saxons *Thong-Castor*, because, it is said, Hengist, after defeating the Scots, obtained from Voltigern as much land as could be inclosed by an ox-hide cut into thongs. It has a grammar-school, with an exhibition at Jesus College, Cambridge. Market-day Saturday. Pop. of parish (1851) 2407.

CAITHNESS, the most northern county of the Scottish mainland, bounded west and south by Sutherlandshire, east and north by the Northern Ocean, situated between Lat. 58. 5. and 58. 40. N., Long. 3. 0. and 3. 55. W.; extreme length 53 miles; extreme breadth 33 miles; extent of coast 105 miles; area 455,708 acres, or 712 square miles, about two-thirds of which is moorland. The form of Caithness nearly resembles an irregular triangle, having as its greatest side the line of coast on the S.E., stretching from the Ord of Caithness to Duncansby Head. The surface of the county generally is flat and tame, consisting for the most part of barren moors, and almost entirely destitute of trees. It presents a gradual slope from the north and east upwards to the ridge of hills on the west and south, which separates it from Sutherlandshire, and which on the southern boundary, where it is bifurcated, attains considerable elevation. The one branch called the Maiden Paps contains the peak of Morven, 2334 above the level of the sea; the other, continuing in the line of the main ridge, juts into the sea, and terminates in the huge granitic precipice called the Ord of Caithness. In the centre of the county, hemmed in by the hills on the western boundary, the ridge of the Maiden Paps, and the sea, is a large undulating plain comprising nearly four-fifths of its whole extent. On its southern side it is broken up by several detached hills, and in the interior contains a considerable number of small lakes. The most depressed part of the county lies in the peninsula, formed in the N.E. corner by the indentation of Dunnet bay and Sinclair bay. The more elevated portion presents a light sandy soil which admits of considerable cultivation, but the low grounds are covered with extensive morasses, producing only heath and rough grass. The geological formation consists chiefly of sandstone, sandstone flag, and occasionally limestone; but granite and gneiss are also found in the west. On the east Caithness presents a precipitous coast, with scarcely a creek in which a vessel, even of small size, can find shelter. On the northern coast, where the Pentland Firth separates it from the Orkney islands, stand at the distance of 13 miles from each other the two bold headlands of Duncansby Head, flanked by two insular "stalks" of freestone, on the N.E. (Lat. 59. 39. N., Long. 30. 1. W.), and Dunnet Head on the N.W. (Lat. 58. 40. N., Long. 3. 21. W.), the most northern point of Scotland. The one is marked by the white steeple of Cannisby on the west, the other by a lighthouse on the rock 346 feet above the level of the sea. The navigation of the Pentland Firth is attended with considerable dangers, from the strength and eddies of the current—the eastern branch of the great Atlantic stream. Off the island of Stroma, which is separated from the Mainland by a strait three miles broad, is a small vortex called the Swalchie, while closer inshore are the "Merry Men of Mey," a group of breakers caused by eddies between projecting headlands. On the east coast, in addition to the harbour of Wick, erected in 1831, at a cost of above L.40,000, there is a small harbour to the south at Sarclet, and another to the north at Staxigoe, a small pier at Clyth and another at Lybster. On the northern coast, Scrabster roads in Thurso bay affords tolerably good anchorage, while at Thurso and Sandside bay are commodious harbours for larger vessels. The climate of Caithness is variable, but not unhealthy; and though the winter storms fall with great severity on the unsheltered coast, yet, from its proximity to a large expanse of sea, the cold is not intense, and snow seldom lies many days continuously. In winter and spring the northern shore is subject to frequent disastrous gales from the N. and N.W. The waters of Reay, Thurso, and Wick, are the principal streams which traverse it, but none of them are of any particular importance. The largest lochs are those of Wattin and Cathel, but there are numerous small ones well stocked with trout. A great change has taken place within the last few years in the agricultural position of Caithness, in consequence of the improved mode of cultivation introduced chiefly by the late James Traill, Esq. of Ratter. That part of the agricultural district which stretches along the coast is still mostly in the hands of small farmers, who cultivate the soil only during the intervals of the fishing-season; but inland, in the more elevated districts, and along the banks of the principal streams, the land is let out into large farms with leases long enough to encourage the holder to improve the soil, and practise a rotation of crops. In the pasturage ground black cattle and sheep, chiefly of the Leicester and Cheviot breeds, are reared for the southern markets; and, independently of the weekly corn-markets at Thurso and Wick, the rapidity of communication with the south is opening up a valuable market for the produce of the dairy and farm yard. The principal crops raised are oats, beans, potatoes, turnips, and a little flax; wheat can be grown only where draining has been carried to considerable perfection.

But the great source of profit to the inhabitants is to be found in the fisheries of cod, ling, lobsters, and herring, which abound all around the coast. The most important is the herring-fishery, beginning about the end of July and lasting for about six weeks, the centre of operations being at Wick and the surrounding districts. The number of fishermen employed in 1853 was 4651; the value of boats, nets, lines, &c., for the same year, was estimated at L.72,203, and the number of barrels of herrings caught was 231,429.[1] Besides these more immediately engaged in manning the boats, the fisheries give employment to a large number of coopers, curers, packers, and others, making in 1853 a total of 9600 persons employed. The salmon-fisheries on the coast and at the mouths of rivers were formerly very productive, and are still let at high prices. Scattered along the coast are valuable quarries of freestone, slate, and of excellent flag for pavements. The county of Caithness is far from rich in other minerals. Slight indications of lead and iron, and it is said of copper, have been found in the mountainous districts; and indications of coal, or rather of bituminous shale, have been noticed at Canisbay. The early history of Caithness may, to some extent, be traced in the various character of the remains and the diversity of its local nomenclature. Picts' houses, Norwegian names, and Danish mounds, attest that the Celts were successively displaced by

[1] Since 1809, according to the Fishery-Board returns, the number of barrels caught has risen from 20,656, to 231,429.

Caius.

these different tribes; and the numbe and strength of its fortified keeps leave us to infer that its annals present the usual record of feuds, assaults, and reprisals. Circles of erect stones, as at Steinster Loch and Bower, the ruins of Popish chapels and places of pilgrimage in almost every district, illustrate the changes which have come over its ecclesiastical condition. The most important remains are those of Bucholie Castle, Girnigoe Castle, and the tower of Keiss; and on the S.E. coast the castles of Clyth, Swiney, Forse, Latheron, Knockinnan, Dunbeath, Achastle, and Berridale. About six miles from Thurso stand the ruins of Braal Castle, the residence of the ancient bishops of Caithness. The principal gentlemen's seats in Caithness are Barrowgill Castle, the residence of the Earl of Caithness; Watten Castle, the residence of Sir R. A. Anstruther, Bart.; Akergill Castle, the residence of Sir George Dunbar, Bart.; Thurso Castle, the residence of Sir George Sinclair, Bart., Castlehill, the residence of George Traill, Esq., M.P. &c.

Caithness is divided into 13 parishes, and contains 13 churches belonging to the Establishment (in 4 of which there is service in Gaelic); 16 belonging to the Free Church (in 8 of which there is service in Gaelic); 1 United Presbyterian, and 1 Roman Catholic.

The county returns one member to the imperial parliament. The parliamentary constituency in 1853 was 683. The principal towns are Wick and Thurso; the most important villages are Broadhaven, Castletown, Louisburgh, Sarclet, and Staxigoe. Pop. (1831) 34,529, (1841) 36,343, (1851) 38,709. Annual value of property assessed (1849) L.71,441.

CAIUS, Kaye, or Keye, Dr John, the founder of Caius College in Cambridge, was born at Norwich in 1510. He was admitted while very young a student in Gonville Hall in the above-mentioned university. From his exercises performed there it seems probable that he intended to prosecute the study of divinity. He travelled into Italy, and at Padua studied under the celebrated Montanus; and in 1541 took his degree in physic at Bologna. In 1543 he visited several parts of Italy, Germany, and France; and returning to England, he began to practise first at Cambridge, then at Shrewsbury, and afterwards at Norwich. He removed to London in 1547, and was admitted fellow of the college of physicians, of which he was several years president. In 1557, being then physician to Queen Mary, he obtained a license to advance Gonville Hall into a college, and he endowed it with several considerable estates, adding an entire new square at the expense of L.1834. Of this college he accepted the mastership, which he held till within a short period of his death. He was physician to Edward VI., Queen Mary, and Queen Elizabeth. Towards the latter end of his life he retired to his own college at Cambridge, where having resigned the mastership to Dr Leggie of Norwich, he spent the remainder of his life as a fellow commoner. He died in July 1573, and was buried in the chapel of his own college. Dr Caius was a learned, active, and benevolent man. In 1557 he erected a monument in St Paul's to the memory of Linacre. In 1563 he obtained a grant for the college of physicians to take the bodies of two malefactors annually for dissection; and he was the inventor of the *insignia* which distinguish the president from the rest of the fellows.

He wrote, 1. Annals of the College from 1555 to 1572. 2. Translation of several of Galen's works, printed at different times abroad. 3. *Hippocrates de Medicamentis;* first discovered and published by Dr Caius; also *De Ratione Victus*, Lov. 1556, 8vo. 4. *De Medendi Methodo*, Basle, 1554; Lond. 1556, 8vo. 5. Account of the Sweating Sickness in England, Lond. 1556, 1721. It is entitled *De Ephemera Britannica.* 6. History of the University of Cambridge, Lond. 1568, 8vo; 1574, 4to, in Latin. 7. *De Thermis Britannicis;* but it is doubtful whether this work was ever printed. 8. Of some Rare Plants and Animals, Lond. 1570. 9. *De Canibus Britannicis*, 1570, 1729. 10. *De Pronunciatione Græcæ et Latinæ Linguæ*, Lond. 1574. 11. *De Libris propriis*, Lond. 1570. Besides many other works which never were printed.

Cajazzo || Calabria.

CAJAZZO, a city of Italy, province of Terra di Lavoro, in the kingdom of Naples, near the Volturno. It has a cathedral, several other churches, and 3500 inhabitants. Excellent wine is produced in the vicinity.

CAJEPUT, a volatile oil obtained by distillation from a species of Melaleuca, which has obtained the name of *melaleuca cajeputi;* cajeputi being its Malay name. This tree, or rather shrub, is a native of the island of Amboyna, and of the southern part of Borneo. Cajeput oil is prepared from the leaves which are collected in a hot dry day, macerated in water, and distilled after fermenting for a night. When distilled it is limpid; but being generally transported to Europe in copper flasks it acquires a greenish colour. When imported in glass bottles, it is perfectly pellucid. It is frequently adulterated. It should be free from colour, or of a bluish-green. This oil is extremely pungent to the taste, and has the odour of a mixture of turpentine and camphor. When dropped in water, it diffuses itself over the surface, and then entirely evaporates. It should burn without leaving any residuum. It is very soluble in alcohol, and sparingly so in water. Like other volatile oils, the cajeput is a powerful stimulant, and is used medicinally where such medicines are required. Some practitioners have given it a high character as a remedy for cholera; but it does not appear to have any claim as a specific in the treatment of that disease. The dose taken internally is about five drops. It is used externally as a rubefacient, and is also resorted to occasionally with advantage in toothache.

CAJETAN, Cardinal, was born at Cajeta in the kingdom of Naples in 1469. His proper name was Thomas de Vio, but he adopted that of Cajetan from the place of his nativity. For his zeal in defending the papal pretensions, in a work entitled *Of the Power of the Pope*, he obtained the bishopric of Cajeta. He was afterwards raised to the archiepiscopal see of Palermo, and in 1517 was made a cardinal by Leo X. The year following he went as legate into Germany, to quiet the commotions raised by Luther against indulgences; but that reformer, under protection of Frederick elector of Saxony, set him at defiance; for though he obeyed the cardinal's summons in repairing to Augsburg, yet he rendered all his proceedings ineffectual. Cajetan was employed in several other negotiations and transactions, being as able in business as in letters. He died in 1534. He wrote commentaries upon Aristotle's philosophy, and upon Thomas Aquinas's theology; and made a free translation of the Old and New Testaments, excepting Solomon's Song and the Prophets, and the Revelation of St John.

CAKE (German *kuchen*), a small mass of dough baked; or a composition of flower, butter, sugar, or other ingredients, baked in a small flattened mass.

CALABAR, Old, a river of Upper Guinea, Africa, which falls into the bight of Biafra by a wide estuary, in Lat. 5. N., Long. 8. 20. E. The Cross river, which was formerly considered a branch of the Calabar, was discovered by Captain Becroft in 1841–2 to be the main stream. See an account of this expedition in the London Geographical Society's Journal, vol. xiv.

Calabar, *New*, a branch of the Quorra river, flowing S.E. and entering the bight of Benin by the same estuary with the Bonny.

CALABASH (Spanish *calabaza*), in *Commerce*, a kind of vessel formed of a dried gourd-shell, or of a calabash shell, used for containing liquors or goods, as pitch, rosin, and the like. Calabash is also a popular name of the *cucurbita* or gourd plant.

CALABRIA, one of the four provinces into which the continental part of the kingdom of Naples, or of the Two Sicilies, was formerly divided, but now the name given to 3 out of the 15 provinces of the later division of that country. It is the most southern part of Italy, being bounded

north by the province of Basilicata, and surrounded east, west, and south by the Mediterranean. It has an area of 6879 square miles, extending from Cape Spartivento (N. Lat. 37. 56.), to Monte Pollino on the southern border of Basilicata (N. Lat. 40. 0.) The coast line, more than 1500 miles in length, is extremely irregular, and indented with numerous bays; but the mouths of the rivers are rendered inaccessible to all but the smallest craft, by the continual accumulation of silt and the smallness of the tides.

The territory is exceedingly rugged and mountainous, but the summits of the hills are covered with extensive forests of oak, beech, elm, and pine, and towards the coast the branches of the Apennines open up into fertile and well-watered valleys. The Apennines traverse its whole extent, entering the province on the north in a direction S.E. to N.W., but afterwards changing their course into S.W. to N.E.; and including the eastern offshoot which occupies the central district of La Sila, they cover nearly the whole breadth of the peninsula. The elevation of the hills is not so great as in the northern, although greater than those in the central provinces; the most prominent peaks are Monte Sila, in Calabria Citra, 4632 feet, and Monte Aspromonte in Calabria Ultra II. 4110 feet. From the main range numerous small branches run off both to the eastern and western shores. The province is well watered with numerous streams, which in the north and south have a short and rapid course and are easily flooded, but in the central district are longer. On the approach of the unhealthy season, the wealthier inhabitants migrate annually to the lofty table-land of La Sila, where their flocks are fattened in the extensive pastures. The agriculture of Calabria, as that of Naples generally, is in a very rude and barbarous condition, a circumstance which is partly attributable to the extreme fertility of the soil. The principal productions are corn, wine, raw silk, oil of an inferior quality, cotton, manna from the manna-ash, rice, liquorice, and saffron. The horses of Calabria are remarkable for their high spirit and compact form, but their numbers are rapidly diminishing, and they are gradually being supplanted by mules. The other stock consists of sheep, goats, oxen, buffaloes, and pigs. All round the coast are considerable fisheries of the tunny, the sword-fish, the anchovy, and mullet.

The inhabitants of Calabria are a brave, hardy, well-built race, but ignorant and half-civilized. Education is chiefly in the hands of priests, who, as a class, are notoriously ignorant. From the oppressive nature of the excise regulations, the lower classes are greatly addicted to smuggling.

The three provinces into which Calabria is now divided are Calabria Citeriore, Calabria Ulteriore Seconda, and Calabria Ulteriore Prima, being so called from their position relative to Naples, and each of them stretching across the peninsula from sea to sea.

Calabria Citeriore is the most northern of the three provinces, and has an area of 2613 square miles, with a population in 1851 of 435,811. The most elevated parts of this province are in the southern and central districts, which are covered by the vast forests of La Sila, and furnished timber for the navies of antiquity. On account of the wastefulness and improvidence of the government, the forests of the Neapolitan Apennines are gradually becoming less productive; and not only is a large amount of timber destroyed, but the decayed vegetable matter has been allowed to dry up the springs and obstruct the mountain streams so as to cover the table-land with pestilential marshes. Corigliano, in the Adriatic, is the principal depot for the timber felled in the province; it is also the principal seat of the manna trade and liquorice factories. The principal rivers are the Crati, which rises near the high-road on the south of Cosenza, and after a course of 60 miles, falls into the Gulf of Taranto, between Capo Spulico and Capo del Trionto; and the Neto, which rises in the heart of La Sila, and falls into the Adriatic, between Strongoli and Cotrone. The principal towns are, Cosenza, Rossano, Paola, and Castrovillari; and these give name to four arrondissements into which the province is subdivided.

Calabria Ulteriore Seconda, on the south of Calabria Citra, having a coast line from the Punta dell' Alice to the Callipari on the east, and from the Savuto to the mouth of the Messina on the west. Area 2100 square miles. Pop. (1851) 381,147. Its principal trade is in manna and saffron, but at Cantazaro is a manufactory of silk, and at Mongiana are iron foundries established by the Neapolitan government. At Maida are some seams of coal, antimony, and alabaster, which might be made available for exports. The principal towns, Cantazaro, Cotrone, Nicastro, and Monteleone, give name to the four arrondissements into which the province is divided.

Calabria Ulteriore Prima, the most southerly province of Italy, contains an area of 1250 square miles, with a pop. (1851) of 319,662. On the northern frontier are the mines Lo Stilo, from which the iron is obtained for the government foundries. At the Villa S. Giovanni is a manufactory of silk thread for foreign consumpt, and at Acciarello a manufactory of soap, but the trade of the province is confined chiefly to raw silk, cotton, fruit, liquorice, wine, brandy, and essential oils. The principal towns are Reggio, Gerace, and Palmi. They are the capitals of the arrondissements which bear their names.

CALABRITTO, a city of Italy, in the Neapolitan province of Principato-Citeriore, with 2160 inhabitants.

CALAHORRA, capital of the judicial district and diocese of the same name, in the province of Logroño, Spain, 24 miles S.E. of Logroño, N. Lat. 42. 12., W. Long. 2. 0. It occupies an elevated site on the left bank of the river Cidacos, near its junction with the Ebro, and contains about 1320 houses, mostly mean, a cathedral in the mixed Gothic style, an episcopal palace, and several conventual and other schools. The climate is cold and damp, but the soil produces in abundance grain, pulse, flax, wine, and oil. Pop. 5994.

Calahorra is the ancient *Calagurris Nassica*, celebrated for its fidelity to Sertorius in his war with Pompey and Metellus; and in the suburbs may still be traced the remains of an ancient Roman circus, an aqueduct, and a naumachia. It is said to have been the birth-place of the rhetorician Quintilian.

CALAIS, a town of France, and capital of a canton of the same name, in the department of Pas de Calais on the south shore of the Straits of Dover, 26 miles E.S.E. of Dover, and 233 miles north from Paris. N. Lat. 50. 57. 45., E. Long. 1. 51. 18. It is built in a rectangular form, having one of its longer sides towards the sea, which washes it on the north and west, while on the east and south it is surrounded by low and marshy ground which easily admits of being flooded so as to strengthen its defences. It is strongly fortified by bastions and forts, and communicates both with the port and the land by means of gates and drawbridges. Overlooking the town on the west stands the citadel, a fortress of great strength, erected by Cardinal Richelieu in 1560. In the centre of the town is the great market-place, in which stands the Hotel de Ville, surmounted by a tower and lighthouse for the shipping, and adorned with busts of the Duke of Guise, Eustache de Saint Pierre, and Cardinal Richelieu. The principal church, erected in the Gothic style by the English during their occupancy of Calais, contains an altar-piece by Vandyk, and is surmounted by a graceful tower. The apartments of Henry VIII. are still pointed out in the Hotel de Guise; and in a suburban wood-yard, a pillar marks the grave of Lady Hamilton, whose history is so painfully associated with that of Nelson. The harbour of Calais is shallow, admitting vessels (of from 400 to 500 tons) only at high water; but the pier, three-quarters of a mile long, forms an agreeable promenade. The principal in-

stitutions are the schools of design and hydrography, the public libraries, and the baths. Its commerce consists chiefly in the exportation of wine, corn, oil, salt, brandy, wood, and eggs; and in the importation of linen, thread, machinery, ironmongery, and colonial produce. Many of the vessels engaged in the cod, herring, and mackerel fisheries, belong to Calais; and the manufacture of bobbin-net in imitation of English goods has so rapidly increased of late that the building of factories has already encroached on the inner ramparts. The use of steam instead of water power has also been greatly extended. Besides these, the manufacture of soap, straw-bonnets, and leather, gives employment to a considerable number of hands. Calais has communication with Dover and London by submarine telegraph laid down in 1851, and by steamers which cross twice a-day. It used to be the principal landing-place for English travellers on the continent, but in this respect has been greatly supplanted by Boulogne. Pop. 12,000, many of whom are English.

Calais continued a petty fishing village with a natural harbour at the mouth of a stream till the end of the tenth century. It was first improved by Baldwin IV. Count of Flanders in 997, and afterwards in 1224 was regularly fortified by Philippe of France, Count of Boulogne. It was besieged by Edward III. after the battle of Crécy, and held out resolutely for eleven months by the bravery of Jean de Vienne the governor. Having been saved, at the intercession of Eustache de Saint Pierre and Queen Philippa, from the cruel fate with which Edward menaced them, the inhabitants were induced to surrender, and left the city to be occupied by an English colony. It continued in the hands of the English till 1558, when it was taken by the Duke of Guise after a short siege of seven days, and the English were expelled. It was held by the Spaniards for two years, 1596–8, till the ratification of the treaty of Vervins.

Calais, Pas de. See Pas de Calais.

CALAMANCO, a sort of woollen stuff, of a fine gloss, and checkered in the warp.

CALAMIANES, a group of small islands in the Asiatic Archipelago, about twelve in number, and situated to the N. and N.E. of the Philippines. They are surrounded by numerous shoals and rocks, which render the navigation intricate and dangerous. The largest of these islands are called Busvagon and Calamiane, the latter of which is about twenty-three miles in length by fifteen in breadth.

CALAMINE, the native carbonate and silicate of zinc, which, though very generally found in the same deposits, differ materially both in their mineralogical and chemical characters. Calamine is generally white or yellow; occasionally, however, it is blue, green, gray, and brown. It varies also from transparent to opaque; has a vitreous lustre; and occurs both crystallized, stalactitic, mamillated, and massive. It is frequently found in veins, associated with blende, and ores of iron and lead. This very useful ore of zinc contains generally from 60 to 70 per cent. of that metal. See Mineralogy, and *Index*.

CALAMIS, a celebrated Greek sculptor, who flourished about 500 B.C. He was a contemporary of Phidias. He wrought in marble, in bronze, and in gold and ivory. Pliny speaks of his horses as being unrivalled. He is noticed by Cicero and Quintilian, and many of his works are mentioned in Pausanias.

CALAMISTRUM, or Calamister, in *Antiquity*, a hollow iron instrument which was used heated for curling the hair. In Cicero's time it was common for the more effeminate of the Roman youth, as well as the matrons, to appear with their hair curled in this way.

CALAMITES, one of the most abundant of the fossils of the coal fields of Europe and America. The original has had the structure of the Calami among recent vegetables.

CALAMUS, (καλάμος), in the ancient poets, a reed-pipe, the musical instrument of shepherds, and usually made of an oaten stalk or a reed. Calamus also denoted a reed-pen, The ancients used a stylus to write on tablets covered with wax, and a reed or rush for writing on parchment or papyrus.

CALAMY, Edmund, an eminent Presbyterian divine, born at London in February 1600, and educated at Pembroke Hall, Cambridge, where his opposition to the Arminian party, then powerful in that society, excluded him from a fellowship. Dr Felton, bishop of Ely, however, made him his chaplain and gave him a living; and in 1639 he was chosen minister of St Mary Aldermanbury in London. Upon the opening of the long parliament he distinguished himself in defence of the Presbyterian cause, and had a principal share in writing the work entitled *Smectymnus*, against episcopacy. The initials of the names of the several contributors formed the name under which it was published, viz. S. Marshal, E. Calamy, T. Young, M. Newcomen, and W. Spurstow. Calamy was afterwards an active member in the assembly of divines, and a strenuous opposer of sectaries; and he used his utmost endeavours to prevent the outrages which were committed after the king was brought from the Isle of Wight. In Cromwell's time he lived privately, but was assiduous in promoting the king's return; for which he was afterwards offered a bishopric, but declined it. He was ejected for nonconformity in 1662 and, on witnessing the devastation of the great fire of London, he was so affected by the sight, that he died shortly afterwards, October 29, 1666.

Calamy, *Edmund*, grandson to the preceding (by his eldest son, Mr Edmund Calamy, who was ejected from the living of Moreton in Essex, in 1662), was born in London, April 5, 1671. After having learned the languages, and gone through a course of natural philosophy and logic at a private academy in England, he studied philosophy and civil law at the university of Utrecht, and attended the lectures of the learned Grævius. While there, an offer of a professor's chair in the university of Edinburgh was made him by Mr Carstairs, principal of that university, sent over on purpose to find a person properly qualified for such an office. This he declined, and returned to England in 1691, bringing with him letters from Grævius to Dr Pococke, canon of Christ Church and regius professor of Hebrew, and to Dr Bernard, Savilian professor of astronomy, who obtained leave for him to prosecute his studies in the Bodleian Library. Having resolved to make divinity his principal study, he entered into an examination of the controversy between the conformists and nonconformists, which determined him to join the latter; and, coming to London in 1692, he was unanimously chosen assistant to Mr Matthew Sylvester at Blackfriars. In 1694 he was ordained at Mr Annesley's meeting-house in Little St Helen's, and soon afterwards was invited to become assistant to Mr Daniel Williams in Hand-Alley. In 1702 he was chosen one of the lecturers in Salters' Hall; and in 1703 he succeeded Mr Vincent Alsop as pastor of a great congregation in Westminster. He drew up the table of contents to Baxter's History of his Life and Times, which was sent to the press in 1696; made some remarks on the work itself, and added to it an index; and, reflecting on the usefulness of the book, he saw the expediency of continuing it, as Baxter's history came no lower than the year 1684. Accordingly he composed an abridgment of it, with an account of many other ministers who were rejected after the restoration of Charles II.; their apology, containing the grounds of their nonconformity and practice as to stated and occasional communion with the Church of England; and a continuation of their history until the year 1691. This work was published in 1702. He afterwards published a moderate defence of nonconformity, in three tracts, in answer to some tracts of Dr Hoadley. In 1709 Mr Calamy made a tour to Scotland, and had the degree of doctor of divinity conferred on him by the universities of Edinburgh, Aberdeen, and Glasgow.

In 1713 he published a second edition of his Abridgment of Baxter's History of his Life and Times; in which, among various additions, there is a continuation of the history through King William's reign and Queen Anne's, down to the passing of the Occasional bill. At the end is subjoined the reformed liturgy, which was drawn up and presented to the bishops in 1661. In 1718 he wrote a vindication of his grandfather and several other persons, against certain reflections cast upon them by Archdeacon Echard in his History of England; and in 1728 appeared his continuation of the account of the ministers, lecturers, masters, and fellows of colleges, and schoolmasters, who were ejected, after the Restoration in 1660, by or before the Act of Uniformity. He died June 3, 1732. Besides the pieces already mentioned, he published a great many sermons on several subjects and occasions. He was twice married, and had thirteen children.

CALANUS, the Indian philosopher who met Alexander in the course of his expedition to that country, and consented to accompany the Macedonian army. But falling very ill at Pasargada in Persia, he committed himself to the funeral pile, after the custom of his sect and country, and perished while reciting the praises of the Hindu deities.

CALAS, Jean, a Protestant merchant at Toulouse, who was barbarously murdered under forms of law which were employed to shelter the sanguinary dictates of ignorant and fanatical zeal. He was born at La Caparède in Languedoc, in 1698, and had lived forty years at Toulouse. His wife was an Englishwoman of French extraction. They had three sons and three daughters. His son Louis had embraced the Roman Catholic faith, through the persuasions of a female domestic who had lived thirty years in the family. In October 1761 the family consisted of Calas, his wife, Marc-Antoine their son, Pierre their second son, and this domestic. Antony was educated for the bar; but being of a melancholy turn of mind, he was continually dwelling on passages from authors on the subject of suicide, and one night in that month he hanged himself in his father's warehouse. The crowd collected on so shocking a discovery, supposed that he had been strangled by the family to prevent him from changing his religion, and that this was a common practice among Protestants. The officers of justice adopted the popular tale, and were supplied by the mob with what they accepted as conclusive evidence of the fact. The fraternity of White Penitents took the body, buried it with great ceremony, and performed a solemn service for the deceased as a martyr; the Franciscans followed their example; and these formalities led to the popular belief in the guilt of the unhappy family. Being all condemned to the rack in order to extort confession, they appealed to the parliament; but this body, being as weak as the subordinate magistrates, sentenced the father to the torture, ordinary and extraordinary, to be broken alive upon the wheel, and then to be burnt to ashes; which diabolical decree was carried into execution on the 9th of March 1762. Pierre Calas, the surviving son, was banished for life: the rest were acquitted. The distracted widow, however, found some friends, and among these Voltaire, who laid her case before the council of state at Versailles; and the parliament of Toulouse was ordered to transmit the proceedings. These the king and council unanimously agreed to annul; the chief magistrate of Toulouse was degraded and fined; old Calas was declared to have been innocent; and every imputation of guilt was removed from the family. See *Causes Célèbres*, tom. iv.

CALASH, (French *calèche*), a light chariot or carriage with very low wheels, used chiefly for taking the air in parks and gardens. Calash also denotes a kind of wide cover for the head, sometimes used by ladies.

CALASIO, Mario de, a Franciscan, and professor of the Hebrew language at Rome, was born in 1550. His concordance of the Bible (which occupied him forty years) was published at Rome in 1621, the year after his death. This work has been highly approved and commended both by Protestants and Roman Catholics, and is indeed an admirable work; for, besides the Hebrew words of the Bible, which compose the body of the book, with the Latin version over against them, there are in the margin the differences between the Septuagint version and the Vulgate; so that at one view may be seen wherein the three Bibles agree, and wherein they differ. At the beginning of every article there is a kind of dictionary, which gives the signification of each Hebrew word; affords an opportunity of comparing it with other oriental languages (Syriac, Arabic, and Chaldee); and is extremely useful for determining more exactly the true meaning of the Hebrew words. It has been several times reprinted; but the original edition is the best.

CALASIRIS, in *Antiquity*, a long Egyptian garment edged below with fringe or tassels. (Herodot. ii. 81.) Also a Persian garment of the same kind.

CALATAFIMI, a city of Sicily, in the intendancy of Trapani. It lies between two hills, in a fine corn country, seven miles S.W. of Alcamo, and contains 10,000 inhabitants. This district is celebrated for its dairy and breeding cattle.

CALATAGIRONE, a town of Sicily, in the province of Catania, and 35 miles S.W. of the town of that name. It is in a very pleasant and salubrious situation, the streets are wide, clean, and well paved, and many of the public buildings are elegant. It is the seat of a bishopric, and has a royal college, hospital, orphan asylum, &c. This is one of the most industrious and commercial towns in the island. Pop. about 22,000.

CALATAYUD, a town of Spain, capital of the district of the same name, in the province of Aragon, 45 miles S.W. of Saragossa, N. Lat. 41. 24., W. Long. 1. 35. It stands on the left bank of the river Jalon, near its confluence with the Jiloca, partly on the plain and partly on a rocky slope, which is covered with remains of ancient Moorish fortifications. It contains about 1000 houses, generally spacious and well-built, several squares, the largest of which is used as the market-place, numerous convents, three hospitals, a fort, a provincial and municipal hall, an episcopal palace, a college, barracks, a theatre, and a bull-arena; there are also two *collegiatas*, or collegiate churches, both of them handsome edifices, and eleven other parish churches. The principal articles of manufacture are coarse brown paper, leather, and woollen stuffs. The soil of the neighbourhood is fertile and well-cultivated. Pop. 7125. Calatayud (*Job's Castle*) is a Moorish city, but stands near the site of the ancient Bilbilis, the birth-place of the poet Martial, and was for the most part built out of its ruins.

CALATHUS, in *Antiquity*, a kind of basket made of light wood or reeds, in which women placed their work, or gathered flowers and fruit. The figure of the calathus, as represented on ancient monuments, is narrow below, and widening towards the top. The calathus of Minerva is celebrated by the poets. Calathus also signified a wine-cup used in sacrifices.

CALATRAVA, a single tower, the remains of an ancient city on the left bank of the Guadiana, New Castile, Spain. It is called *Calatrava la Vieja*, in order to distinguish it from *Calatrava la Nueva*, a convent founded in the neighbourhood by the knights of Calatrava.

Calatrava, Knights of, a military order in Spain, instituted by Sancho III. king of Castile, upon the following occasion. When that prince took the strong fort of Calatrava from the Moors of Andalucia, he gave it to the Templars, who wanting courage to defend it returned it to him again, A.D. 1157. Then Don Raymon, of the order of the Cistercians, accompanied by several persons of high rank, offered to defend the place, which the king thereupon delivered up to them, giving them a charter as the knights of Calatrava. This order increased so much under Alphonso, that the knights desired to have a grand master, who was accord-

ingly appointed. Ferdinand and Isabella, with the consent of Pope Innocent VIII., afterwards reunited the grand mastership of Calatrava to the Spanish crown, so that the kings of Spain became perpetual administrators of this office. The knights of Calatrava bear a cross gules, fleur-de-lised with green. Their rule and habit were originally those of the Cistercians. (Fr. de Rader y Andrada, *Cronica de las tres ordines de Sanctiago, Calatrava, y Alcantara*, Toledo, 1572, fol.; Rev. E. Clarke's *Spain*.)

CALAURIA, in *Ancient Geography*, an island of Greece, in the Saronic bay, over against the port of Troezen, was celebrated for its temple of Poseidon. Hither Demosthenes fled to escape from Antipater, and poisoned himself.

CALCAR, JOHN DE, an eminent painter, born at Calcar, in the duchy of Clèves, in 1499. He was a disciple of Titian at Venice, and perfected himself by studying Raphael. He imitated those masters with the greatest success. Among his various pieces is a Nativity representing the angels around the infant Christ; which he arranged so that the light emanated from the child. He died at Naples in 1546. (Vasari.)

CALCAREOUS SPAR, or CRYSTALLIZED CARBONATE OF LIME, one of the most generally diversified substances in the mineral kingdom, and certainly that which presents the greatest variety of crystalline forms. Haüy has drawn and described upwards of 500 of these; and since his time not fewer than 800 other distinct modifications have been determined, all of which, when fractured, present as their primitive form an obtuse rhomb of 105° 5′ and 74° 55′. The most prevalent colour of calcareous spar is white, though it also presents numerous shades of yellow, green, blue, and red, most of them pale. Its dark brown and black colours are owing to the admixture of bitumen. It is transparent or translucent, and has in the clear specimens a very distinct double refraction. It has a vitreous lustre, and perfect cleavage. The pure varieties consist, according to the analyses of Stromeyer and Phillips, of—

Lime	56·15	55·50
Carbonic acid	43·70	44·00;

but the coloured ones not unfrequently contain small portions of oxide of iron, silica, magnesia, alumina, carbon, and bitumen. It effervesces violently with acids, and if pure is entirely soluble in nitric acid. At an ordinary heat it does not fuse, but gives off its carbonic acid, shines with a peculiar brightness, and ultimately becomes quicklime. Among the most distinguished localities of calcareous spar may be enumerated Andreasberg and other mining districts in the Hartz, where the varieties in six-sided prisms have been found of great beauty; Alston Moor in Cumberland, which affords numerous flat rhombic crystals; and Derbyshire, whence the pyramidal forms, sometimes of very large dimensions, are obtained. Under the head of calcareous spar there are a number of sub-species, which depend chiefly upon their mode of composition, and upon admixtures and impurities, with which the individuals have been affected at their formation. See MINERALOGY.

CALCEARIUM, in *Antiquity*, money given to the Roman soldiers to purchase shoes. In monasteries, *calcearium* denoted the service of cleaning shoes.

CALCEDONY. The distinction between this substance and agate rests upon very arbitrary grounds. Agate frequently presents a variety of colours, and a multiplicity of beautiful delineations. Calcedony is generally of one uniform colour, of a light brown, and sometimes nearly white. It occurs in irregular masses, forming grotesque cavities in the trap rocks, particularly in Iceland and the Faroe Isles, from the former of which there are specimens in the Museum of Edinburgh of a very large size. These stalactites appear always to have proceeded from the upper part of the cavity, which is sometimes filled up to the very summit with solid matter. From a close examination of these specimens, we are led to believe that the material must have been introduced into the cavity either in a state of the most attenuated fluidity, or even in a gaseous form. The structure can be traced down the sides of the cavity, regularly surrounding every portion of the stalactite, and passing across the horizontal plate which uniformly forms the base of these cavities. A slight intermixture of opalescent matter, which renders the calcedony more white and opaque, delineates this structure in the most perfect manner, and is a common occurrence in Faroe.

Calcedony is not confined to the trap rocks; it occurs in granite; and the most beautiful specimens known were found in one of the mines of Cornwall, distinguished by the name of Trevascus. It was, however, in one solitary cell that these occurred. Although the mine has continued to yield calcedony of the same character, nothing similar to these magnificent specimens has been produced since. They can scarcely be compared to anything which they resemble more than the anatomized wing of a large bat, exhibiting the bones and arteries in the most perfect manner. One of these beautiful specimens, which was in the possession of the late Mr Greville, is now in the British Museum.

Calcedony is used for the construction of cups and plates, and other articles of taste, of which the most splendid specimens are imported into this country from India. The labour which has been bestowed in the manufacture of these articles, and the perfection with which it has been accomplished, is a matter of surprise to all who examine them. There are some of them as thin and as delicate as china. The finest stones are of course selected for this purpose. They are generally clear and almost transparent, still maintaining the warm brown colour which characterizes the stone. They often have the appearance of having been hammered, so shaded and undulated is the aspect of the mass; and to add to their beauty, the fine dendritic Mocha stones are often selected. We are in ignorance even of the locality where these beautiful objects are manufactured, whether in Japan or China; but to this country they generally come from India, where, we believe, they are found among the most precious jewels in the repositories of the nabobs and princes of the East.

Calcedony in Europe is confined to labours on a much smaller scale, such as knife-handles, and mortars for chemical purposes; also for snuff-boxes, buttons, and other minor objects. The principal manufactory is at Oberstein in the Palatinate.

Calcedony is semitransparent; its texture is fine and compact; the fracture is scaly, resembling that of wax; it is less hard than rock crystal, but gives fire with steel. No indications of regular form have ever been observed in this substance; for we need not except the pale blue variety from Tresztyan in Transylvania, which is decidedly a pseudomorphic formation in the form of fluor spar. Calcedony frequently assumes the forms of other minerals, as well as of shells in many instances; but these may be considered as accidents unconnected with the history of the substance.

Connected with agate and calcedony, we may at once enumerate the different varieties which are still maintained by mineralogists.

1. Sardonyx (quartz, agate, sardoine of the French). This variety is characterized by a rich orange colour.

2. Carnelian (cornaline of the French). The characteristic colour of this variety is a brilliant red.

3. Prase (the chrysoprase of the Germans). This variety occurs at Kosmütz in Silesi. It sometimes possesses a most brilliant green colour, and is nearly transparent.

4. Plasma, semitransparent, and of a dark grass-green colour. It was very much used by the ancients as a stone for engraving.

5. Onyx (the band-agate of the Germans). This stone, when of favourable colours, is used by artists for forming cameos.

Mineralogists have split the agate into a variety of other denominations, which are not worth enumerating.

CALCEOLARIA, a very ornamental genus of plants introduced into Britain from the western slopes of the South American Andes. They belong to the natural order of *Scrofularineæ*. Most of them have yellow slipper-shaped flowers, but great variety of colour has been produced by forming hybrids.

CALCEUS, or CALCIUS, in Roman antiquity, a shoe or half boot. The Romans, when reclining at table, laid aside their shoes; hence *calceos poscere*, to rise from table. The form and colour of the calceus sometimes denoted the rank of the wearer; hence the phrase *calceos mutare*, to become a senator.

CALCHAS, a famous soothsayer who followed the Greek army to Troy. He foretold that the siege would last ten years; and that the fleet, which was detained in the port of Aulis by contrary winds, would not sail till Agamemnon's daughter had been sacrificed to Diana. After the taking of Troy he retired to Colophon, where (as an oracle had foretold) he died of grief because he was unable to divine certain events which the soothsayer Mopsus had predicted.

CALCINATION, the operation of reducing a substance to a powder, or to a friable state, by the action of heat. See CHEMISTRY.

CALCIUM, the metallic basis of lime. See CHEMISTRY.

CALC-SINTER, or STALACTITIC CARBONATE OF LIME. This occurs mamillated, or in long pendulous masses or tubes, commonly coating, or even entirely filling, the interior of caves. Though deposited from water loaded with particles of lime, and therefore in a constant state of formation, these stalactites (which outside are commonly of a yellowish-white colour, and present an infinity of different shapes and sizes) invariably afford when broken the most distinct cleavage. In this way the perfect rhomb, having the same angles as that of the calcareous spar, is easily produced from any portion of them. The extensive caverns of Adelsberg in Carniola derive their entire splendour from the thousands of these stalactites with which they are naturally ornamented in the shape of festoons, curtains, foliage, and whatever else a lively imagination may choose to invent out of the variety of fanciful and extraordinary forms they assume. These caverns constitute a labyrinth of many miles within the porous limestone rocks of the vicinity, and as yet perhaps but a small portion of them has been explored. (See ADELSBERG.) The cave of Macallister, commonly called the Spar Cave, on Loch Sunart in the Isle of Skye, is another of the same description, though much inferior in extent and beauty to that of Adelsberg. The oriental alabaster, which is this same mineral in a massive state, was much prized by the ancients for statuary purposes.

CALC-TUFF, or CALCAREOUS TUFA, is the most impure, the most irregular, and the most porous, of all the varieties of limestone. It occurs in beds generally in the vicinity of lakes and rivers; also encrusting rocks, and enveloping animal and vegetable remains in the proximity of calcareous springs. Immense deposits of calc-tuff have taken place at Terni, and on the banks of the river Anio near Tivoli; where some very curious impressions, such as that of a cart-wheel, trunks of trees, &c., are to be met with. The celebrated Grecian temples of Pæstum are formed of this stone, and no doubt owe their existence at the present period to the circumstance of its becoming harder the longer it is exposed to the air; for, as the quarries whence it has been procured are in the immediate vicinity, and the stone previous to being exposed is so much softer, modern Vandals have found it easier to go directly to the quarry for what they wanted, than attack the long weather-beaten and now indurated Doric pillars of the temples. From its property of hardening so much on exposure to the atmosphere and to water, this rock makes a very useful building stone in the formation of bridges. Over the Danube at Ulm a very handsome bridge has been constructed of this stone, which, when brought from the neighbouring mountains, is cut into the required dimensions with the assistance merely of the axe and the saw.

CALCULI, little stones or pebbles anciently used in making computations, taking suffrages, playing at draughts, and the like. In after times, pieces of ivory, of silver, gold, and other materials, were used in lieu of the calculi, but still retained the ancient name. Computists, when they were slaves or newly freed men, were called *calculones;* those of a better condition were named *calculatores* or *numerarii*. There was ordinarily one of these in each family of distinction. The Roman judges anciently gave their opinions by calculi, which were white for absolution, and black for condemnation. Hence *calculus albus* denoted a favourable vote, either in the case of a person to be acquitted of a charge, or elected to some dignity or post; and *calculus niger* had a contrary signification. This usage is said to have been borrowed from the Thracians, who marked their happy or prosperous days by *white*, and their unhappy by *black* pebbles, which were put each night into an urn.

Besides the diversity of colour, there were some calculi also which had figures or characters engraven on them; as those used in taking the suffrages in the senate and in assemblies of the people. Their form is still seen in some medals of the Cassian family; and the manner of casting them into the urns is represented on the medals of the Licinian family. The letters marked upon these calculi were U. R. for *uti rogas*, and A. for *antiquo;* the first of which expressed an approbation of the law, the latter a rejection of it. Afterwards the judges who sat in capital causes used calculi marked with the letter A. for *absolvo;* C. for *condemno;* and N. L. for *non liquet*, signifying that more full information was required.

CALCULI, *Urinary*. See CHEMISTRY, and SURGERY.

CALCULUS, in late Latin, signified a small weight, equal to two grains of *cicer* (chick-pea). Two calculi were equal to the Greek κεράτιον, and to the Latin *siliqua*.

CALCULUS, in *Mathematics*, is a general name given to various ways of investigating or establishing the truths of that science by the aid of conventional symbols or characters which represent the things treated of; also the operations to be performed on them, and the relations in which they stand to one another. Thus we have the common *Arithmetical* Calculus, and the *Algebraic* Calculus. The term is applied to a considerable number of distinct mathematical theories, the principal of which are these:

The *Differential* CALCULUS and the *Integral* CALCULUS. The invention of these is claimed for Leibnitz. They are identical with the *Fluxionary* CALCULUS, the invention of Newton.

The CALCULUS *of Partial Differences*, which is a branch of the Differential and Integral Calculus.

The CALCULUS *of Variations*, another branch of the same theory. Its principal object is to determine when mathematical qualities, subject to certain conditions, are the greatest or least possible. This theory, first broached by James and John Bernouilli, was perfected by Euler and La Grange, who have discussed it in their writings. See a distinct treatise on this subject by Mr Woodhouse of Cambridge.

The CALCULUS *of Exponentials*, or Exponential Calculus. This may include the doctrine of logarithms; but the name is commonly applied to the method of finding the differentials or fluxions of exponential and logarithmic quantities. John Bernouilli was the first who treated of this subject as a distinct calculus. (Bernouilli *Opera*, tom. i. p. 179.)

The CALCULUS *of Functions*, the same in effect with the Differential or Fluxionary Calculus. La Grange gave this name to his particular view of the subject. (*Théorie des Fonctions Analytiques;* also *Leçons sur le Calcul des Fonctions*.)

The CALCULUS *of Finite Differences*. This investigates the properties of quantities by means of their differences. It is of great value in the summation of infinite series. Brooke Taylor's *Methodus Incrementorum*, Stirling's *Methodus Differentialis*, and Emerson's *Method of Increments*, also his *Differential Method*, all treat of this subject. There are also various treatises in works on the Differential Calculus, as Lacroix, &c.

The CALCULUS *of Derivations*. This is applicable to the doctrine of series, and is due to a Continental mathematician, Arbogast, who has composed a treatise on the subject. (Arbogast, *Du Calcul des Dérivations*.)

The CALCULUS *of Probabilities*. This treats of everything connected with the *Doctrine of Chances*. The most valuable work on this subject is La Place's *Théorie Analytique des Probabilités*. See also De Morgan's work.

The CALCULUS *of Sines*. This branch of mathematical science was embodied in a distinct form by Euler. See his various writings, particularly his *Analysis Infinitorum*. We have explained this calculus in our article ALGEBRA.

There are some other mathematical theories which have been distinguished each as a separate *Calculus*, as Landen's *Residual Analysis*, Glennie's *Antecedental Calculus* (*Edin. Phil. Trans.* vol. iv.), &c.

CALCULUS Minervæ, in *Antiquity*, denoted the decision of a cause in regard to which the judges were equally divided. The expression is taken from the story of Orestes, at whose trial before the Areopagites, for the murder of his mother, the votes being equally divided for and against him, Minerva interposed and gave the casting vote or calculus in his behalf.

CALCUTTA, one of the largest and most splendid cities of Asia, the modern capital of Hindustan, and the seat of the supreme government of the British in India. It is situated on the left bank of the river Hooghly, which forms the western channel of the Ganges, and is distant by the river's course about one hundred miles from the sea. The country from the mouth of the Hooghly to Diamond Harbour is dreary in the extreme; the banks of the river are high, and the adjacent land on each side, which is perfectly flat, forms a complete wilderness of timber and brushwood, the haunt of tigers and other beasts of prey. Advancing up the river the scene gradually improves, the country becomes more and more cultivated, the shipping and the bustle on the river increase, and the beautiful country seats on its banks announce proximity to the capital. The city, with its numerous spires and other public edifices, presents at a distance a striking appearance, and on landing the magnificence of the buildings commands the admiration of all strangers. The town extends along the left or eastern bank of the river for the distance of four miles and a half, having an average breadth of about a mile and a half, and covering an area of eight square miles. Near the landing place, called "Old Fort Ghat," is a large square, each side measuring above two hundred and fifty yards. The middle is occupied by a fine tank or open reservoir of water for the supply of the town. This square forms the centre of what is properly termed the town or business quarter of Calcutta, in contradistinction to the fashionable or court end, Chowringhee, containing the residences of Europeans, and of natives of distinction. To the north along the bank of the river, lies the Black Town, which is occupied entirely by natives.

About a quarter of a mile to the south of the commercial quarter, and opposite to Chowringhee stand Fort-William and the barracks, which form on this side a great ornament to the city. The intermediate space, which is an extensive open plain, is termed the esplanade. The citadel of Fort-William, which was begun by Lord Clive in 1757 after the battle of Plassey, is the strongest and most regular fortress in India, but the works are so extensive that they would require at least 9000 or 10,000 men, with 600 pieces of cannon, to defend them. On the west of the esplanade stands the Government-house (erected by the Marquis Wellesley), which is the largest and most splendid building in Calcutta. It is the residence of the governor-general, where he holds levees, and transacts all the government business; it also contains magnificent apartments for public entertainments. The custom-house faces the river, and forms part of the west side of the great square. It is built upon the site of the Old Fort which was taken in 1757 by Surajah Dowlah. Near to it is the famous Black Hole, which is now converted into a warehouse; and before the gate stands the monument which has been erected as a memorial of the unfortunate persons who perished there. It is surrounded by an iron railing, but since it was struck by lightning, it has been allowed to go to decay. In front of the custom-house is the quay, which is of essential service to the numerous ships which there load and unload. The other public buildings are, the town-hall situate on the esplanade, built in the Doric style of architecture, and containing public rooms which, though handsome, are too confined for the climate, and for the number of the inhabitants; the supreme court of justice; the Mohammedan and Hindu Colleges; La Martinière (an educational institution supported by funds bequeathed by General Claude Martin, originally a common soldier in the French army, but subsequently a major-general in the East India Company's service); the Ochterlony monument raised in honour of Sir David Ochterlony, and designed in the Saracenic style of architecture as indicative of the high estimation in which the general held the followers of Islam; Metcalfe Hall, erected by subscription as a public testimonial to the character of Lord Metcalfe. At the S.W. angle of the fort is a ghat formed to perpetuate the memory of James Prinsep, one of the most eminent men of his age; and a little beyond is the monument raised to commemorate the victories of Maharajpore and Punniar, and constructed from the cannon captured on those fields. St Paul's cathedral is a fabric recently erected through the exertions and munificence of Bishop Wilson, aided by a pecuniary grant from the East India Company. Of places of worship 167 are devoted to the Hindu religion, and 74 to that of the Mohammedans. The Chinese have a temple, and the Jews a synagogue. There are three Baptist chapels, and two belonging to Independents not Baptists. There is one Greek and one Armenian church, and five Roman Catholic chapels. Of those connected with the national churches of Great Britain, the Church of England has eight, the Established Church of Scotland one, and the Free Church of that country one.

About three miles below Calcutta, on the opposite side of the river, and in a beautiful situation, stands the botanic garden, giving to a bend of the river the name of Garden Beach. It contains a splendid collection of plants from every quarter of the globe, and is laid out with great taste, but more with a view to practical utility than scientific arrangement. Horse-racing having been discouraged by government, the course, which was to the south of the town, is now converted into a ride; but the practice still continues at Barrackpoor, sixteen miles higher up the river, where the fashionable society of Calcutta assemble to partake of the amusement. The south side of the Tank Square is occupied by Writers' buildings, which make but an indifferent appearance. They form the residence of the civil servants of the Company who have newly arrived from Europe, and who are students at the college of Fort-William. The private houses in Calcutta, in the central part of the town, are built mostly after the European fashion, but modified to the nature of the climate, and to the magnificence of eastern manners. At Chowringhee, in a line with Government-house, is a range of elegant buildings ornamented with large verandahs, and another at right

angles with it, formerly occupied by native huts. These houses are built of brick covered with a species of stucco called chunam. They are all separated from each other, every one having attached to it a considerable piece of inclosed ground, in the middle of which it is situated. The approach is by a flight of steps under a large portico. The architecture is Grecian, and the profusion of columns, porticoes, and verandahs, gives to these buildings the air more of palaces than of private houses. To this part of Calcutta, the Black Town, which extends along the river to the north of Calcutta, forms a striking contrast. It is built after the model of Indian towns, is very large, and swarms with inhabitants. The streets are exceedingly narrow and crooked. Of late years, however, this quarter of the town has been greatly improved both in appearance and in salubrity; the streets have been widened and properly drained, and ponds have been filled; a large surface of stagnant water has been thereby removed, the exhalations from which were prejudicial to health; and the houses have been rendered less combustible by the substitution of tiles for thatch.

Calcutta is the great emporium of India. By means of the Ganges and its tributary streams it has an uninterrupted water communication with the whole of the lower provinces of Bengal, and also with the fertile territory subject to the jurisdiction of the lieutenant-governor of Agra. Being thus advantageously situated for commerce, it trades extensively with almost every country in the world, and numbers of vessels of every form and description are constantly arriving in or departing from the river, which in the vicinity of the town presents the busiest scene imaginable. Numerous dockyards have also been established, in which are built vessels of great burden and of admirable construction. Indigo, sugar, cotton, rice, opium, silk, and saltpetre, are the staple commodities of export. Those of import are British cotton goods, salt, copper, iron, and hardware.

The commerce of Calcutta has for a long period of years enjoyed the advantage of a bank, called the Bank of Bengal, established by government authority, and carried on under government inspection. Various acts have at different periods been passed by the government of India for its regulation; the last bears date the 18th March 1839, and took effect from the 1st May following. By this all previous charters and acts, except so far as continued by the new act, were cancelled and repealed; the capital stock previously fixed at 75 lacs of rupees was increased by one half; the nature of the transactions in which the bank might engage was prescribed, and the conditions and limitations under which its business was to be conducted were laid down. The stock is divided into shares of 4000 rupees, or quarter shares of 1000 rupees each; and a portion is and always has been held by government.

The educational institutions in Calcutta are numerous. Of these the principal are the Madrissa or Mohammedan College, founded by the British government in 1781, with the view of gratifying national predilections, and thus to gain over the learned and influential classes, and further to secure a regular supply of Mohammedan officers for the courts of law; the Sanscrit College, for which a handsome building has been erected, founded in 1821 for similar objects with respect to the other great division of the population, the Hindus; the Hindu College, established originally by native subscription, chiefly for the instruction of Hindu youths in the English language and the literature and science of Europe; Bishop's College, founded for the purpose of instructing native youths and others in the doctrines and discipline of Christianity, in order to their becoming preachers, catechists, and schoolmasters, under the Society for the Propagation of the Gospel in Foreign Parts. In 1823 a committee of public instruction was formed, who were authorized to exercise superintendence over all government seminaries, and to give an impulse as well as a judicious direction to efforts made for diffusing instruction among the native population. Subsequently the committee merged into a council of education, which still exists, but acts ministerially under the direction of the government. Under the patronage of a society of European ladies, native schools for girls, with female teachers, were established in 1821; and there is a female normal school, superintended by a committee, of which Mrs Mackenzie, well known in the literary world, is honorary secretary. Mr Bethune, for some time legislative member of the council of India, also established a female school, which subsequently was transferred to government. There are two schools for the education and maintenance of the children of Europeans in the military service of the Company, one for the children of officers, and the other for those of the privates. The charitable institutions are numerous: among these may be noticed St James' Schools, instituted by Bishop Middleton; the European Female Orphan Asylum; the Benevolent Institution, designed for the instruction of indigent Christian children; the Free School; the Church Missionary Alms-Houses; the Leper Asylum; and the General Assembly's Institution. There are several literary and scientific societies. The Asiatic Society, inaugurated under the patronage of Sir William Jones, still continues its sittings and the publication of its transactions, containing much interesting and curious matter relating to the history, literature, languages, and antiquities of Asia.

A census of the population taken in May 1850, by order of the chief magistrate, gives the following results :—

Europeans,	6,233
Eurasians (the progeny of European fathers and native mothers),	4,615
Americans	892
Chinese,	847
Asiatics,	15,342
Hindus,	274,335
Mohammedans,	110,918
	413,182

The occupations of these various classes are nearly what might be expected in the luxurious capital of a great empire, and in so great an emporium of maritime commerce. Public officers, lawyers, physicians, merchants, and their families, make up the bulk of the British inhabitants. The natives and foreigners of respectability are mostly engaged in trade, or live upon their property; and the lower classes are principally composed of retail dealers, mechanics, and servants.

The British merchants form a most respectable class, and contribute essentially to the prosperity of the settlement. Many of them are possessed of large fortunes, and live in a style of suitable splendour. The Armenians are the most numerous body of foreign merchants in Calcutta. They trade extensively to all parts of the East, are uncommonly diligent and attentive to business, and are considered to have a more minute intelligence from foreign ports than any other body of merchants. The native bankers, agents, and money-dealers, are numerous. Though formerly timorous, the Hindu now adventures in almost every species of mercantile speculations; and goods belonging to native merchants, to the amount of several millions sterling, are generally lying for sale in the warehouses of Calcutta. The native merchants of an inferior class engross nearly the whole of the retail trade of Calcutta, under the titles of Banians, Sircars, and other appellations. In the transactions of usury these men are watchful and acute beyond even those engaged in similar pursuits in the west.

The English society in Calcutta is of the best description, and numerous fêtes are given during the cold season, which lasts from September to April, on a splendid scale, by the governor-general and other public functionaries, as well as

by private individuals. There is a theatre, chiefly supported by amateur performers; and public concerts are given, also supported by amateur talent. The usual mode of visiting is in palanquins, but many of the British have carriages adapted to the climate; and the breed of horses having been greatly improved, it is the universal practice to drive out between sunset and dinner. It is only during the cold season that it is possible to venture abroad in the heat of the day, which, in the rest of the year, is devoted to repose. The hot season begins in April. Every day the heat increases until the middle of June, when the periodical rains begin, which last till August. The weather then being extremely close, is more oppressive and more unhealthy than before. The mean temperature is about 66° in January, 69° in February, 80° in March, 85° in April and May, 83° in June, 81° in July, 82° in August and September, 79° in October, 74° in November, and 66° in December. The annual fall of rain during six years, commencing with 1830, averaged sixty-four inches.

Calcutta is about to be lighted with gas, a company having been formed for the purpose. Farther improvements may be anticipated. The present mode of communication between Howra, on the opposite bank of the river, and the metropolis, is by ferry; but Howra has been selected as the locality for the terminus of the East India railway; and upon the opening of the first section, which is now complete, greater facilities will be required, as well of access from Howra as of egress from the city in the same direction. Various contrivances have been suggested, but it is obvious that any expedient will be inadequate until the Hooghly shall have been spanned by a substantial bridge in the immediate vicinity of the terminus.

It was in the last year of the seventeenth century that the East India Company obtained from Aurungzebe, emperor of Delhi, the grant of certain villages scattered over the site now occupied by the city of Calcutta. To this locality the Company's factory was removed from the town of Hooghly; and the necessary works of defence being raised, the new settlement, in compliment to the reigning king of England, received the name of Fort-William. One of the villages, transferred to the British, was called Calcutta, and hence the appellation by which the metropolis of India has been since known. Such at no distant period was the lowly origin of the seat of government, whence a foreign nation now gives law to the whole of India.

In 1752 a ditch was dug round a considerable part of the town, as a barrier against the inroads of the Mahrattas. The trade of Bengal alone supplied rich cargoes for many ships annually, besides what was carried on in small vessels to the adjacent countries It was this flourishing state of Calcutta which probably induced the nabob Surajah Dowlah to attack it in the year 1756. Having had the fort of Cossimbazar delivered up to him, he marched against Calcutta with all his forces, and invested the place. Disunion, and the cowardice of some whose efforts ought to have been exerted in defence of the settlement, facilitated the triumph of the nabob. It being resolved to remove the females to a ship lying in the river, two civil servants of the Company, named Manningham and Frankland, volunteered to superintend their departure, and having thus effected their escape refused to return. The governor, Mr Drake, followed their example; and in the conduct of affairs, Mr Holwell then assumed the first place by unanimous consent, Mr Peake an elder member of council foregoing his claim. Ultimate success was hopeless, and the defence was protracted only to afford opportunity for an escape to a ship in the river. But this hope failed—the ship, through the unskilfulness of the pilot, having taken the ground. Signals were then made, and constantly repeated, to the vessel in which the previous fugitives had found safety, but without effect. The result was not only the fall of the place, but the capture of its unfortunate inmates. A hundred and forty-six of these were forthwith consigned for the night to a horrible dungeon, only about eighteen feet square, from which only twenty-three came out alive in the morning. The injuries which Calcutta suffered at this time, however, were soon repaired. The place was retaken by Admiral Watson and Colonel Clive early in 1757; Surajah Dowlah was defeated, deposed, and put to death; and Meer Jaffier succeeded him in the nabobship. Since that time the immense acquisition of territory by the British in this part of the world, and the constant state of security enjoyed by this city, have raised it to its present prosperity and splendour. Fort-William stands in Long. 88. 25. E., Lat. 22. 33. N. (E. T.)

CALDANI, L. MARCO ANTONIO, a distinguished Italian anatomist and physician, was born at Bologna in 1725. After holding various minor appointments, he was chosen assistant to the celebrated anatomist Morgagni at Padua; but disgusted with the envy which his distinguished position drew down upon him, he withdrew to Venice. Soon after, however, he was appointed to the professorship of the theory of medicine, with the promise of being elected to succeed Morgagni, who was now very old and infirm. In 1771 he published his *Elements of Pathology*, and soon afterwards the *Elements of Physiology*. In this same year he took possession of the chair of anatomy, vacant by the death of Morgagni, and endeavoured, though without success, to found an anatomical museum. At the age of seventy-six, though threatened with blindness, he published, with the assistance of his nephew, a valuable series of anatomical plates. He died in 1813, at the age of eighty-eight.

CALDARIUM, in the ancient Roman baths, a vessel containing warm water for bathing. See BATHS.

CALDER, a river of Yorkshire, which rises on the borders of Lancashire, near Burnley, and after a winding eastward course of about 40 miles, joins the Aire. It receives during its course several smaller streams, and is navigable for nearly 30 miles, forming part of the canal system of Yorkshire and Lancashire. On its banks are the towns of Dewsbury and Wakefield.

CALDERINUS, DOMITIUS, a very learned critic, born at Torri, near Caldiero, in the vicinity of Verona, A.D. 1445. He read lectures upon polite literature at Rome with great reputation, and he also wrote commentaries on many of the ancient poets. He died in 1477, aged thirty-two.

CALDERON DE LA BARCA, DON PEDRO, a celebrated Spanish dramatic author, born of noble parentage at Madrid in 1601. Having early completed his studies, he attached himself to some patrons about court; but being soon disgusted with this state of dependence he enlisted as a common soldier, and made several campaigns in Italy and Flanders. During this time, however, he cultivated a taste for dramatic poetry; and having attracted the notice of Philip IV., who was a passionate admirer of the drama, that prince invited Calderon to Madrid in 1636, made him a knight of the order of St Iago, and was guided by his advice in all matters connected with the theatricals of the court. It is also said that during the minority of Louis XIV. Calderon visited Paris, and composed verses in praise of Anne of Austria, the destined bride of Philip IV. In 1652, he devoted himself to the church, and became a canon at Toledo. From this period till that of his death, which happened on the 25th of May 1681, he abandoned dramatic composition, except on sacred subjects. His works are very numerous, exceeding, it is said, five hundred. No nation, in fact, can boast of such prolific writers as Spain. Lopez de Vega, for instance, is said to have composed two thousand *comedias;* a fertility which would be less surprising if the pieces themselves were of an inferior order, or destitute of merit; but though deformed by the most extraordinary faults they are at the same time enlivened by brilliant coruscations of genius and fancy. It must, however, be admitted that Virvez, and particularly Lopez and Calderon, had begun, even in the age of Cervantes, to corrupt the Spanish drama. Before their time, the productions of Castillejo and of Juan de la Cueva were more regular, though less forcible, spirited, and interesting; but after their appearance the unities were totally disregarded, and dramatic writers assumed a degree of license which was pushed to the utmost height of extravagance. Cervantes opposed himself strenuously to this innovation, but in vain. Lopez and Calderon were as well acquainted with the established rules as Cervantes himself; but they

knew only to despise them. The judicious author of the *Bibliothèque Espagnol* places Calderon on a footing of equality with Lopez de Vega, and says that this was the general opinion among their contemporaries. But Linguet, in his *Théatre Espagnol*, hesitates not to place Calderon in the first rank; whilst Emmanuel de Guerra says that Calderon imitated no one (*a ninguno imito*), and drew from his own imagination alone. This is indeed evident; for his delineations are deficient in truth, and his characters are altogether fantastical. The pieces of Calderon, like those of the Spanish theatre generally, are divided into three *days* or acts, and the scene is often changed. His comedies almost always exhibit vice triumphant; and it cannot with any truth be said of him, *castigat ridendo mores.* The *gracioso* or buffoon is, for the most part, one of his principal characters; and sometimes, as in *Heraclius*, a couple of these personages are introduced. The piece of Calderon entitled *No ai burlas con el Amor* appears to have suggested to Molière the idea of his *Femmes Savantes;* while the one entitled *Nunca la peor es cierto* has been grossly disfigured by Scarron in his comedy of *La Fausse Apparence.* Lastly, the infamous Collot d'Herbois caused to be represented, with a certain degree of success, in 1777, on one of the provincial theatres of France, and again in 1789, in the Théatre Français at Paris, the *Paysan Magistrat*, imitated from the piece of Calderon entitled *Alcalde de Zalamea.* Besides his plays, Calderon composed a considerable number of *Autos Sacramentales*, or sacred pieces, analogous to those which are elsewhere denominated *Mysteries, Acts of the Saints*, and *Moralities.* Calderon is not relished in France, and comparatively little known in Britain.. In Germany, however, he enjoys a great reputation. Schlegel has translated some of his best pieces; while his *Constant Prince*, and *Life is a Dream*, have been repeatedly represented with success on the boards at Weimar. The former of these pieces is generally considered as the masterpiece of Calderon. The works of Calderon were reprinted at Madrid in 1726 and 1760, in ten volumes 4to; and a collection of his *Autos Sacramentales* appeared at Madrid in 1759, in six volumes 4to. His manuscript *Letters* are preserved among the archives of the house of Calderon.

CALDERWOOD, David, an industrious historian of the Church of Scotland, and a strenuous defender of its discipline, was born in 1575. He was educated at Edinburgh, where he took the degree of A.M. in 1593. About 1604 he became minister of Crailing near Jedburgh; and he speedily began to take a conspicuous part in the ecclesiastical proceedings of that period.

The king was extremely anxious to assimilate the Church of Scotland to the Church of England. Having succeeded in obtruding episcopacy, it was the next object of his solicitude to enlarge the authority and jurisdiction of the bishops. His schemes were however opposed by many of the clergy; nor was any one more resolute in his opposition than Calderwood.

In 1617 James paid a visit to Scotland. During the sitting of the parliament, which assembled on the 17th of June, the clergy held several meetings in the Little Church, one or more of the bishops being always present. The general conduct of the high Episcopalian functionaries was such as to fill many of the Presbyterian clergy with alarm; so that at last a considerable number of them having assembled in the music-school, they resolved upon drawing up a remonstrance to his Majesty. Two of the Edinburgh clergy, Hewat and Struthers, were appointed to prepare it; and when it was fully adjusted, Archibald Simson, minister of Dalkeith, was directed to sign it as clerk of the meeting; but the names of all those who attended were subscribed in a separate paper, which was delivered to him as a voucher to be used according to circumstances. He presented a copy to the clerk register, who refused to read it in parliament; and having been summoned before the High Commission, he declined to produce the signatures, and was committed as a prisoner to the castle of Edinburgh. This paper he had entrusted to the master of the music-school, Patrick Henryson, who delivered it to Calderwood. The minister of Crailing was therefore cited to appear at St Andrews on the 8th of July, and there to exhibit the roll of names, and "to answer for his mutinous and seditious assistance to the said assembly." Hewat and Simson were summoned at the same time, and they all made their appearance; but their examination was deferred till the 12th, in order that it might take place in his Majesty's presence. James conducted himself in his usual manner; but the stern and undaunted Calderwood was not to be overawed by any earthly authority which he conceived to be unjustly exercised. The king having at length whispered in the primate's ear, "his Majesty," he stated, "saith that if ye will not be content to be suspended spiritually ye shall be suspended corporally." Undismayed by this declaration, he replied, "Sir, my bodie is in your Majesty's hands to do with it as it pleaseth your Majesty; but as long as my bodie is free, I will teach, notwithstanding of their sentence."

Hewat, adhering to the protestation, was deprived, and confined in the town of Dundee; but as he had obtained a grant of the temporalities of Crossragwell abbey he was not left without a provision. Simson, who had aggravated the original offence by writing a letter in which he disparaged the English bishops, likewise received sentence of deprivation, and was for several months detained in prison; but on making his submission he was at length reinstated. A similar sentence was pronounced on Calderwood, who was committed to prison at St Andrews, and was afterwards removed to Edinburgh. The privy-council, which long exercised an undefined and despotic jurisdiction, ordained him to be banished from the kingdom for refusing to acknowledge the sentence of the High Commission; and the whole proceedings in this case exhibit a curious example of the arbitrary and iniquitous administration of that period. On giving security to banish himself from the kingdom before the ensuing Michaelmas, and not to return without the royal license, he was released from prison. He accompanied Lord Cranstoun to Carlisle, where that nobleman presented to the king a petition in his favour; but it was followed by no beneficial result. The subsequent application of Lord Cranstoun to the privy-council, and to the bishops, was attended with no better success.

He continued for a considerable time to linger in his native country; and during this interval he began the publication of his anonymous works in support of the Presbyterian cause. In 1618 he printed a Latin tract on the polity of the Church of Scotland. The general assembly, which met at Perth on the 25th of August, gave a new impulse to his mind: and in 1619 he produced an English work, in which he undertook to demonstrate the nullity of the assembly itself, and the unlawfulness of its five articles, relating to kneeling at the communion, the observance of festivals, confirmation, private baptism, and private communion.

While Calderwood was still lurking in Scotland, an attempt was made to apprehend him at Edinburgh, in the house of James Cathkin, a bookseller; but the officers neither found him nor any copies of his obnoxious publication relative to the *Perth Assembly.* Calderwood was in the mean time concealed at Cranstoun, in a secret apartment allotted to him by Lady Cranstoun, who rendered him many services. He afterwards removed from one place to another, till the 27th of August 1619, when he embarked at Newhaven, and sailed for Holland. Where he chiefly resided in that country we are not informed; but Bishop

Calderwood. Guthry states, that "in the time of his exile he had seen the wild follies of the English Brownists in Arnheim and Amsterdam."[1] During his residence in Holland he published various works, and, among the rest, his *Altare Damascenum*. At one period his enemies supposed him to be dead; and he has recorded a very extraordinary attempt to impose upon the world a recantation fabricated in his name.[2]

Calderwood appears to have returned to Scotland in 1624. He was still found to be the most redoubtable champion of presbytery; and after the abolition of episcopacy, he was appointed minister of Pencaitland, in the county of Haddington. During the remainder of his life, he continued to take an active part in the affairs of the church; and as firmness may be nearly allied to obstinacy, he appears to have maintained his own opinions with habitual keenness. It was he that introduced the practice, which is now confirmed by long usage, of dissenting from the decision of the assembly, and requiring the protest to be entered in the record. In 1649, an act having been introduced respecting the election of ministers, he proposed that the right of electing should be vested in the presbytery, leaving to the people the power of declaring their dissent, upon reasons of which it should be competent for the presbytery to judge; but this suggestion was not adopted; and, according to Baillie's statement, "Calderwood entered a very sharp protestation against our act, which he required to be registered. This is the first protestation we heard of in our time; and had it come from any other it had not escaped censure."[3]

He devoted many years to the preparation of a History of the Church of Scotland. In 1648 the general assembly urged him to complete the design, and voted him a yearly pension of eight hundred pounds.[4] He left behind him an historical work of great extent, and of great value, not indeed as a masterly composition, but as a storehouse of authentic materials for history. An abridgment, which appears to have been prepared by himself,[5] was published after his death. An excellent edition of this important work has been recently published by the Wodrow Society. The author's manuscript, which lately belonged to General Calderwood Durham, has been presented to the British Museum. A copy, transcribed under the inspection of Wodrow, is among the archives of the church; another belongs to the library of the university of Glasgow; and, as Dr M'Crie has stated, "in the Advocates' Library, besides a complete copy of that work, there is a folio volume of it, reaching to the end of the year 1572. It was written in 1634, and has a number of interlineations and marginal alterations, differing from the other copies, which, if not made by the author's own hand, were most probably done under his eye."[6]

Calderwood died at Jedburgh on the 29th of October 1650,[7] aged seventy-five. He appears to have been a man of unbending integrity, fearless in maintaining his opinions, and uniformly consistent in his professions; but as human virtues are never perfect, his decision of character had some tendency to deviate into that obstinacy of humour from which good men are not always exempted.

His works are numerous; and as they were almost all published without the author's name, it is not easy to form a complete and accurate catalogue. The place of printing is omitted in all the original editions, but several, if not most of them, appear to have been printed in Holland.

Caldron || Caldwall. CALDRON, or CAULDRON (French *chaudron*, Latin *caldarium*), a large kitchen utensil of copper or iron with a moveable handle by which to hang it on the chimney-hook.

CALDWALL, or CHALDWALL, RICHARD, a learned physician, born in Staffordshire, about 1513. He studied physic in Brasen-nose College, Oxford, and was examined, admitted into, and made censor of, the College of Physicians at London, all in one day. Six weeks after he was chosen one of the elects; and in 1570 he was made president of that college. Wood says that Caldwall wrote several essays on professional subjects. Camden mentions that he founded, and handsomely endowed, a chirurgical lecture in the College of Physicians. These lectures, known as the *Lumleian Lectures*, are still given. He died in 1585.

CALEDONIA, the ancient name of Scotland. From the testimonies of Tacitus, Dio, and Solinus, we find that the ancient Caledonia comprehended all that country situated to the north of the rivers Forth and Clyde. In proportion as the Silures or Cimbri advanced northwards, the Caledonians, circumscribed within narrower limits, were forced to pass over into the islands which fringe the western coasts of Scotland. It is about this period, probably, that we ought to fix the first great migration of the British Gael into Ireland; that kingdom being much nearer to the promontory of Galloway and Cantyre than many of the Scottish isles are to the continent of North Britain.

To the country which the Caledonians possessed they gave the name of *Gael-doch*, which is the only appellation the Scots who speak the Gaelic language know for their own division of Britain. *Gael-doch* is a compound formed from *Gael*, the first colony of the ancient Gauls who transmigrated into Britain, and *doch*, a district or division of a country. The Romans, by transposing the letter *l* in *Gael*, and by softening into a Latin termination the *ch* of *doch*, formed, it is supposed, the well-known name of Caledonia This name, according to Chalmers, is merely the Latinized form of *Celyddoni*, from *Celyddon*, the descriptive appellation given to the country by the British colonists, and signifying literally *the Coverts*.

At the period when Agricola invaded North Britain, A.D. 81, that portion of the island appears to have been possessed by twenty-one tribes of aboriginal inhabitants, having little or no political connection with one another, although evidently identical in origin, in language, in customs, and in manners. The names and topographical positions of these Caledonian tribes or clans have been preserved and pretty accurately ascertained. They were, 1. The *Ottadini*, or *Ottadeni*, who occupied the S.E. boundary of North Britain, extending along the whole line of coast from the southern Tyne to the Firth of Forth, and including the half of Northumberland, the eastern part of Roxburghshire, and the whole of Berwickshire and of East Lothian; 2. The *Gadeni*, who inhabited the interior of the country, to the west of the *Ottadini*, including the western part of Northumberland, a small part of Cumberland to the north of the Irthing, the western part of Roxburghshire, the whole of Selkirkshire, Tweeddale, a considerable part of Mid-Lothian, and nearly all West Lothian; their pos-

6 M'Crie's *Life of Knox*, vol. i p. vi.—Some of his papers are preserved among Wodrow's MSS. in the Advocates' Library. Two original letters from John Paget to Calderwood occur in M. 6. 9. No. 107–8.

7 *Bannatyne Miscellany*, vol. i. p. 205. Baillie, in a passage already quoted, mentions that Calderwood was sixty-six years old in 1641.

sessions extending from the Tyne on the south to the Firth of Forth on the north; 3. The *Selgovæ*, who inhabited Annandale, Nithsdale, and Eskdale in Dumfriesshire, and the eastern part of Galloway as far as the river Deva or Dee, which was their western boundary; 4. The *Novantæ*, who possessed the middle and western parts of Galloway, from the Dee on the east to the Irish Sea on the west; on the south they were bounded by the Solway Firth and the Irish Sea, and on the north by the chain of hills which separates Galloway from Carrick; 5. The *Damnii*, the most important of the southern tribes, who inhabited the whole extent of country from the ridge of hills which separates Galloway from Ayrshire on the south, to the river Earne on the north, and possessed all Strathclyde, the shires of Ayr, Renfrew, and Stirling, and a small part of those of Dumbarton and Perth; 6. The *Horestii*, who inhabited the country between *Bodotria* or Forth on the south, and the *Tavus* or Tay on the north, comprehending the shires of Clackmannan, Kinross, and Fife, with the eastern part of Strathern, and the country westward of the Tay as far as the river Brann; 7. The *Venecontes* who possessed the territory between the Tay on the south and the Carron on the north, comprehending Gowrie, Strathmore, Stormont, and Strathardle in Perthshire, together with the whole of Angus, and the larger part of Kincardineshire; 8. The *Taizalæ*, who inhabited the northern part of the Mearns, and the whole of Aberdeenshire as far as the Doveran; 9. The *Vacomagi*, who inhabited the country on the south side of the Moray Firth, from the Doveran on the east to the Ness on the west, comprehending the shires of Banff, Elgin, Nairn, the eastern part of Inverness, and Braemar in Aberdeenshire; 10. The *Albani*, afterwards called *Damnii-Albani*, who possessed the interior districts between the lower ridge of the Grampians, which skirts the southern side of the loch and river Tay on the south, and the chain of mountains which forms the southern limit of Inverness-shire on the north; 11. The *Attacoti*, who inhabited the whole of the country from Lochfyne on the west to the eastward of the river Leven and Lochlomond, comprehending the whole of Cowal in Argyleshire and the greater part of Dumbartonshire; 12. The Caledonii proper, who inhabited the whole of the interior of the country from the ridge of mountains which separates Inverness and Perth on the south, to the range of hills which forms the forest of Balnagowan in Ross on the north, comprehending all the middle parts of Inverness and Ross; 13. The *Cantæ*, who possessed the east of Ross from the Moray Firth on the south to the Firth of Dornoch on the north; 14. The *Logi*, who possessed the south-eastern coast of Sutherland, extending from the Dornoch Firth on the S.W. to the Helmsdale river on the east; 15. The *Cornabii*, who inhabited the south, the east, and the N.E. of Caithness, from the Helmsdale river, comprehending the three great promontories of Noss-head, Duncansby-head, and Dunnet-head; 16. The *Careni*, a small tribe who inhabited the north-western corner of Caithness, and the eastern half of Strathnaver in Sutherlandshire, having the river Naver, the *Navari fluvius* of Ptolemy, for their western boundary; 17. The *Mertæ*, who occupied the interior of Sutherland; 18. The *Carnonacæ*, who inhabited the northern and western coast of Sutherland, and a small part of the western shore of Ross, from the Naver on the east to the *Volsas* bay on the S.W.; 19. The *Cerones*, who inhabited the western coast of Ross, from the *Volsas* bay on the north to Lochduich on the south; 20. The *Cerones*, who inhabited the whole western coast of Inverness, and the districts of Ardnamurchan, Morven, Sunart, and Ardgower in Argyleshire, having Lochduich on the north, and the Linne-loch on the south; and, 21. The *Epidii*, who inhabited the S.W. of Argyleshire, from Linne-loch on the north, to the Firth of Clyde and the Irish Sea on the south, including Cantyre [illegible] the country of the *Albani*, and by Lochfyne. Such, according to the best authorities, were the names and geographical positions of the twenty-one tribes which, at the time of the Roman invasion, occupied the whole of North Britain.

When the tribes of North Britain were attacked by the Romans under Agricola (see article Britain, chap. i.), they entered into associations, in order that, by uniting their strength, they might be more able to repel the common enemy. But the particular name of the tribe which either its superior power or military reputation placed at the head of the association, was the general name given by the Romans to all the confederates. Hence it is that the *Mœatæ*, who inhabited the districts of Scotland lying southward of the Firth, and the *Caledonians*, who inhabited the west and N.W. parts, engrossed the glory which belonged in common, though in an inferior degree, to the other tribes settled of old in North Britain.

The origin of the appellations *Scoti* and *Picti*, introduced by the later Roman authors, has occasioned much controversy among antiquaries in modern times. It seems tolerably certain, however, that the Scots and Picts were one and the same people; or rather, that the term *Picti* or Picts was the generic, and that of *Scoti* or Scots, only a specific appellation. Eumenius the orator, who first mentions the Picts, alludes to the *Caledones aliique Picti;* an expression which implies that the *Caledones* and *other* tribes were considered as Picts. Again, with reference to the question whether the Scots were aboriginal Britons, or merely emigrants from Ireland, it has been shown by arguments which appear to be invincible, that they came originally from Ireland; but, on the other hand, it seems equally certain that the Scots of Ireland, or the *Scoticæ gentes* of Porphyry, a branch of the great Celtic family, passed over, at a very remote period, from the shores of Britain into Ireland, and before the beginning of the fifth century had given their name to the whole of that country. Their name, however, does not occur in the Roman annals till A.D. 360; but all the authors of the fourth century agree that Ireland was the proper country of the Scots, and that they invaded the Roman territories in North Britain about the period above mentioned. They are described as an erratic or wandering race, who carried on a predatory system of warfare, and also as a transmarine people, who came from Ireland, their native island. Under the denomination of Picts were included the Caledonians and Scots, and probably also the Attacots, a warlike clan, settled on the shores of Dumbarton and Cowal. See Scotland.

Caledonia, New, an island in the South Sea, discovered by Captain Cook. See Australasia.

CALEDONIAN Canal. See Navigation, Inland; and Scotland.

CALELLA, a small seaport town of Spain, in the province of Barcelona, in Lat. 41. 37. N., Long. 2. 45. E. It numbers about 600 houses, and contains a hospital, a college of primary instruction, a parish church, and a prison. Besides a considerable transit trade, there is carried on an active manufacture of cotton fabrics and blond-lace; while shipbuilding and the distilling of brandy give employment to a part of the population, which amounts to 3035.

CALENBERG, a principality of Hanover, in the arrondissement of Hanover, bounded north by Hoya and Lüneburg; east by Lüneburg and Hildesheim; south by Brunswick; west by Lippe-Detmold, Pyrmont, Schaumburg, and Schaumburg-Lippe. Area 1050 square miles. The northern part is flat and covered with patches of moorland, the southern part is hilly, with broad and fertile valleys intervening. It is traversed by the Weser and the Leine, and derives its name from the ancient Castle of Calenberg on the Leine, once a princely residence, but now in ruins. The chief town in the principality is Hanover. Pop. 19,300.

CALENDAR.

A CALENDAR is a method of distributing time into certain periods adapted to the purposes of civil life, as hours, days, weeks, months, years, &c.

Of all the periods marked out by the motions of the celestial bodies, the most conspicuous, and the most intimately connected with the affairs of mankind, are the *solar day*, which is distinguished by the diurnal revolution of the earth and the alternation of light and darkness, and the *solar year*, which completes the circle of the seasons. But in the early ages of the world, when mankind were chiefly engaged in rural occupations, the phases of the moon must have been objects of great attention and interest; hence the *month*, and the practice adopted by many nations of reckoning time by the motions of the moon, as well as the still more general practice of combining lunar with solar periods. The solar day, the solar year, and the lunar month, or lunation, may therefore be called the *natural* divisions of time. All others, as the hour, the week, and the civil month, though of the most ancient and general use, are only arbitrary and conventional.

Day.—The true solar day is the interval of time which elapses between two consecutive returns of the same terrestrial meridian to the sun, and therefore, by reason of the inclined position of the ecliptic, and the unequal progressive motion of the earth in its orbit, is not always of the same absolute length. But as it would be hardly possible, in the artificial measurement of time, to have regard to this small inequality, which is besides constantly varying, the *mean solar day* is employed for all civil purposes. This is the time in which the earth *would* make one revolution on its axis, as compared with the sun, if the earth moved at an equable rate in the plane of the equator. The mean solar day is therefore a result of computation, and not marked by any astronomical phenomenon; but its difference from the true solar or apparent day is so small as to escape ordinary observation.

The subdivision of the day into twenty-four parts, or hours, has prevailed since the remotest ages, though different nations have not agreed either with respect to the epoch of its commencement or the manner of distributing the hours. Europeans in general, like the ancient Egyptians, place the commencement of the civil day at midnight, and reckon twelve morning hours from midnight to midday, and twelve evening hours from midday to midnight. Astronomers, after the example of Ptolemy, regard the day as commencing with the sun's culmination, or noon, and find it most convenient for the purposes of computation to reckon through the whole twenty-four hours. Hipparchus reckoned the twenty-four hours from midnight to midnight. Some nations, as the ancient Chaldeans and the modern Greeks, have chosen sunrise for the commencement of the day; others, again, as the Italians and Bohemians, suppose it to commence at sunset. In all these cases the beginning of the day varies with the seasons at all places not under the equator. In the early ages of Rome, and even down to the middle of the fifth century after the foundation of the city, no other divisions of the day were known than sunrise, sunset, and midday, which was marked by the arrival of the sun between the Rostra and a place called Græcostasis, where ambassadors from Greece and other countries used to stand. The Greeks divided the natural day and night into twelve equal parts each, and the hours thus formed were denominated *temporary hours*, from their varying in length according to the seasons of the year. The hours of the day and night were of course only equal at the time of the equinoxes. The whole period of day and night they called νυχθημερον.

Week.—The week is a period of seven days, having no reference whatever to the celestial motions; a circumstance to which it owes its unalterable uniformity. Although it did not enter into the calendar of the Greeks, and was not introduced at Rome till after the reign of Theodosius, it has been employed from time immemorial in almost all eastern countries; and as it forms neither an aliquot part of the year nor of the lunar month, those who reject the Mosaic recital will be at a loss, as Delambre remarks, to assign to it an origin having much semblance of probability. It might have been suggested by the phases of the moon, or by the number of the planets known in ancient times, an origin which is rendered more probable from the names universally given to the different days of which it is composed. In the Egyptian astronomy, the order of the planets, beginning with the most remote, is Saturn, Jupiter, Mars, the Sun, Venus, Mercury, the Moon. Now, the day being divided into twenty-four hours, each hour was consecrated to a particular planet, namely, one to Saturn, the following to Jupiter, the third to Mars, and so on according to the above order; and the day received the name of the planet which presided over its first hour. If, then, the first hour of a day was consecrated to Saturn, that planet would also have the 8th, the 15th, and the 22d hour; the 23d would fall to Jupiter, the 24th to Mars, and the 25th, or the first hour of the second day, would belong to the Sun. In like manner the first hour of the 3d day would fall to the Moon, the first of the 4th day to Mars, of the 5th to Mercury, of the 6th to Jupiter, and of the 7th to Venus. The cycle being completed, the first hour of the 8th day would return to Saturn, and all the others succeed in the same order. According to Dio Cassius, the Egyptian week commenced with Saturday. On their flight from Egypt, the Jews, from hatred to their ancient oppressors, made Saturday the last day of the week.

The English names of the days are derived from the Saxon. The ancient Saxons had borrowed the week from some eastern nation, and substituted the names of their own divinities for those of the gods of Greece. In legislative and justiciary acts the Latin names are still retained.

Latin.	English.	Saxon.
Dies Solis.	Sunday.	Sun's day.
Dies Lunæ.	Monday	Moon's day.
Dies Martis.	Tuesday.	Tiw's day.
Dies Mercurii.	Wednesday.	Woden's day
Dies Jovis.	Thursday.	Thor's day.
Dies Veneris.	Friday.	Friga's day.
Dies Saturni.	Saturday.	Seterne's day.

Month.—Long before the exact length of the year was determined, it must have been perceived that the synodic revolution of the moon is accomplished in about 29½ days. Twelve lunations, therefore, form a period of 354 days, which differs only by about 11¼ days from the solar year. From this circumstance has arisen the practice, perhaps universal, of dividing the year into twelve *months*. But in the course of a few years the accumulated difference between the solar year and twelve lunar months would become considerable, and have the effect of transporting the commencement of the year to a different season. The difficulties that arose in attempting to avoid this inconvenience induced some nations to abandon the moon alto-

gether, and regulate their year by the course of the sun. The month, however, being a convenient period of time, has retained its place in the calendars of all nations; but, instead of denoting a synodic revolution of the moon, it is usually employed to denote an arbitrary number of days approaching to the twelfth part of a solar year.

Among the ancient Egyptians, the month consisted of thirty days invariably; and in order to complete the year, five days were added at the end, called supplementary days. They made use of no intercalation, and by losing a fourth of a day every year, the commencement of the year went back one day in every period of four years, and consequently made a revolution of the seasons in 1461 years. Hence 1461 Egyptian years are equal to 1460 Julian years of 365¼ days each. This year is called *vague*, by reason of its commencing sometimes at one season of the year, and sometimes at another.

The Greeks divided the month into three decades, or periods of ten days; a practice which was imitated by the French in their unsuccessful attempt to introduce a new calendar at the period of the revolution. This division offers two advantages; the first is, that the period is an exact measure of the month of thirty days; and the second is, that the number of the day of the decade is connected with and suggests the number of the day of the month. For example, the 5th of the decade must necessarily be the 5th, the 15th, or the 25th of the month; so that when the day of the decade is known, that of the month can scarcely be mistaken. In reckoning by weeks, it is necessary to keep in mind the day of the week on which each month begins.

The Romans employed a division of the month and a method of reckoning the days which appears not a little extraordinary, and must, in practice, have been exceedingly incommodious. Instead of distinguishing the days by the ordinal numbers first, second, third, &c. they counted *backwards* from three fixed epochs, namely, the *Calends*, the *Nones*, and the *Ides*. The Calends were placed invariably on the first day of the month, and were so denominated because it had been an ancient custom of the pontiffs to call the people together on that day, to apprize them of the festivals, or days that were to be kept sacred during the month. The Ides (from an obsolete verb *iduare*, to divide) were at the middle of the month, either the 13th or the 15th day; and the Nones were the *ninth* before the Ides, counting inclusively. From these three terms the days received their denomination in the following manner:—Those which were comprised between the Calends and the Nones were called *the days before the Nones;* those between the Nones and the Ides were called *the days before the Ides;* and, lastly, all the days after the Ides to the end of the month were called *the days before the Calends* of the succeeding month. In the months of March, May, July, and October, the Ides fell on the 15th day, and the Nones consequently on the 7th; so that each of these months had six days named from the Nones. In all the other months the Ides were on the 13th and the Nones on the 5th; consequently there were only four days named from the Nones. Every month had eight days named from the Ides. The number of days receiving their denomination from the Calends depended on the number of days in the month and the day on which the Ides fell. For example, if the month contained 31 days, and the Ides fell on the 13th, as was the case in January, August, and December, there would remain 18 days after the Ides, which, added to the first of the following month, made 19 days of Calends. In January, therefore, the 14th day of the month was called the *nineteenth before the Calends of February* (counting inclusively), the 15th was the 18th before the Calends, and so on to the 30th, which was called the third before the Calends (*tertio Calendas*), the last being the second of the Calends, or the day before the Calends (*pridie Calendas*). As frequent allusion is made by classical writers to this embarrassing method of computation, which is carefully retained in the ecclesiastical calendar, we will here give a table showing the correspondence of the Roman months with those of modern Europe.

Year.—The year is either astronomical or civil. The solar astronomical year is the period of time in which the earth performs a revolution about the sun, or passes from any point of the ecliptic to the same point again; and consists of 365 days 5 hours 48 minutes and 49·62 seconds of mean solar time. The civil year is that which is employed in chronology, and varies among different nations, both in respect of the season at which it commences, and of its subdivisions. When regard is had to the sun's motion alone, the regulation of the year, and the distribution of the days into months, may be effected without much trouble; but the difficulty is greatly increased when it is sought to reconcile solar and lunar periods, or to make the subdivisions of the year depend on the moon, and at the same time to preserve the correspondence between the whole year and the seasons.

Of the Solar Year.—In the arrangement of the civil year, two objects are sought to be accomplished: the first is, the equable distribution of the days among twelve months; and the second is, the preservation of the beginning of the year at the same distance from the solstices or equinoxes. Now, as the year consists of 365 days and a fraction, and 365 is a number not divisible by 12, it is impossible that the months can all be of the same length,

and at the same time include all the days of the year. By reason also of the fractional excess of the length of the year above 365 days, it likewise happens that the years cannot all contain the same number of days if the epoch of their commencement remains fixed; for the day and the civil year must necessarily be considered as beginning at the same instant; and therefore the extra hours cannot be included in the year till they have accumulated to a whole day. As soon as this has taken place, an additional day must be given to the year.

The civil calendar of all European countries has been borrowed from that of the Romans. Romulus is said to have divided the year into ten months only, including in all 304 days, and it is not very well known how the remaining days were disposed of. The ancient Roman year commenced with March, as is indicated by the names September, October, November, December, which the four last months still retain. July and August, likewise, were anciently denominated Quintilis and Sextilis, their present appellations having been bestowed in compliment to Julius Cæsar and Augustus. In the reign of Numa two months were added to the year, January at the beginning, and February at the end; and this arrangement continued till the year 452 B. C., when the Decemvirs changed the order of the months, and placed February after January. The months now consisted of twenty-nine and thirty days alternately, to correspond with the synodic revolution of the moon, so that the year contained 354 days; but a day was added to make the number odd, which was considered more fortunate, and the year therefore consisted of 355 days. This differed from the solar year by ten whole days and a fraction; but, to restore the coincidence, Numa ordered an additional or intercalary month to be inserted every second year between the 23d and 24th of February, consisting of twenty-two and twenty-three days alternately, so that four years contained 1465 days, and the mean length of the year was consequently $366\frac{1}{4}$ days. The additional month was called *Mercedinus*, or *Mercedonius*, from *merces*, wages, probably because the wages of workmen and domestics were usually paid at this season of the year. According to the above arrangement, the year was too long by one day, which rendered another correction necessary. As the error amounted to twenty-four days in as many years, it was ordered that every third period of eight years, instead of containing four intercalary months, amounting in all to ninety days, should contain only three of those months, consisting of twenty-two days each. The mean length of the year was thus reduced to $365\frac{1}{4}$ days; but it is not certain at what time the octennial periods, borrowed from the Greeks, were introduced into the Roman calendar, or whether they were at any time strictly followed. It does not even appear that the length of the intercalary month was regulated by any certain principle, for a discretionary power was left with the pontiffs, to whom the care of the calendar was committed, to intercalate more or fewer days according as the year was found to differ more or less from the celestial motions. This power was quickly abused to serve political objects, and the calendar consequently thrown into confusion. By giving a greater or less number of days to the intercalary month, the pontiffs were enabled to prolong the term of a magistracy, or hasten the annual elections; and so little care had been taken to regulate the year, that, at the time of Julius Cæsar, the civil equinox differed from the astronomical by three months, so that the winter months were carried back into autumn, and the autumnal into summer.

In order to put an end to the disorders arising from the negligence or ignorance of the pontiffs, Cæsar abolished the use of the lunar year and the intercalary month, and regulated the civil year entirely by the sun. With the advice and assistance of Sosigenes, he fixed the mean length of the year at $365\frac{1}{4}$ days, and decreed that every fourth year should have 366 days, the other years having each 365. In order to restore the vernal equinox to the 25th of March, the place it occupied in the time of Numa, he ordered two extraordinary months to be inserted between November and December in the current year, the first to consist of thirty-three, and the second of thirty-four days. The intercalary month of twenty-three days fell into the year of course, so that the ancient year of 355 days received an augmentation of ninety days; and the year on that occasion contained in all 445 days. This was called the last year of confusion. The first Julian year commenced with the 1st of January of the 46th before the birth of Christ, and the 708th from the foundation of the city.

In the distribution of the days through the several months, Cæsar adopted a simpler and more commodious arrangement than that which has since prevailed. He had ordered that the first, third, fifth, seventh, ninth, and eleventh months, that is January, March, May, July, September, and November, should have each thirty-one days, and the other months thirty, excepting February, which in common years should have only twenty-nine, but every fourth year thirty days. This order was interrupted to gratify the vanity of Augustus, by giving the month bearing his name as many days as July, which was named after the first Cæsar. A day was accordingly taken from February and given to August; and in order that three months of thirty-one days might not come together, September and November were reduced to thirty days, and thirty-one given to October and December. For so frivolous a reason was the regulation of Cæsar abandoned, and a capricious arrangement introduced, which it requires some pains to remember.

The additional day which occurred every fourth year was given to February, as being the shortest month, and was inserted in the calendar between the twenty-fourth and twenty-fifth day. February having then twenty-nine days, the twenty-fifth was the sixth of the calends of March, *sexto calendas;* the preceding, which was the additional or intercalary day, was called *bis-sexto calendas*, hence the term *bissextile*, which is still employed to distinguish the year of 366 days. The English denomination of *Leap-Year* would have been more appropriate if that year had differed from common years in *defect*, and contained only 364 days. In the ecclesiastical calendar the intercalary day is still placed between the 24th and 25th of February; in the civil calendar it is the 29th.

The regulations of Cæsar were not at first sufficiently understood; and the pontiffs, by intercalating every third year instead of every fourth, at the end of thirty-six years had intercalated twelve times instead of nine. This mistake having been discovered, Augustus ordered that all the years from the thirty-seventh of the era to the forty-eighth inclusive should be common years, by which means the intercalations were reduced to the proper number of twelve in forty-eight years. No account is taken of this blunder in chronology; and it is tacitly supposed that the calendar has been correctly followed from its commencement.

Although the Julian method of intercalation is perhaps the most convenient that could be adopted, yet, as it supposes the year too long by 11 minutes 10·35 seconds, it could not without correction very long answer the purpose for which it was devised, namely, that of preserving always the same interval of time between the commencement of the year and the equinox. Sosigenes could scarcely fail to know that his year was too long; for it had been shown

long before, by the observations of Hipparchus, that the excess of $365\frac{1}{4}$ days above a true solar year would amount to a day in 300 years. The real error is indeed more than double of this, and amounts to a day in 129 years; but in the time of Cæsar the length of the year was an astronomical element not very well determined. In the course of a few centuries, however, the equinox sensibly retrograded towards the beginning of the year. When the Julian calendar was introduced, the equinox fell on the 25th of March. At the time of the Council of Nice, which was held in 325, it fell on the 21st; and when the reformation was made in 1582, it had retrograded to the 11th. In order to restore the equinox to its former place, Pope Gregory XIII. directed ten days to be suppressed in the calendar; and as the error of the Julian intercalation was now found to amount to three days in 400 years, he ordered the intercalations to be omitted on all the centenary years excepting those which are multiples of 400. According to the Gregorian rule of intercalation, therefore, every year of which the number is divisible by four without a remainder, is a leap year, excepting the centurial years, which are only leap years when divisible by four after suppressing the two zeros. Thus 1600 was a leap year, but 1700, 1800, and 1900, are common years; 2000 will be a leap year, and so on.

As the Gregorian method of intercalation has been adopted in all Christian countries, Russia excepted, it becomes interesting to examine with what degree of accuracy it reconciles the civil with the solar year. According to the best determinations of modern astronomy (Bailli's *Tables*, p. 16), the solar year consists of 365 days 5 h. 48 min. 49·62 sec. or 365·242241 days. Now the Gregorian rule gives 97 intercalations in 400 years; 400 years therefore contain $365 \times 400 + 97$, that is, 146,097 days; and consequently one year contains 365·2425 days, or 365 d. 5 h. 49 min. 12 sec. This exceeds the true solar year by 22·38 seconds, which amount to a day in 3866 years. It is perhaps unnecessary to make any formal provision against an error which can only happen after so long a period of time; but as 3866 differs little from 4000, it has been proposed to correct the Gregorian rule by making the year 4000 and all its multiples common years. With this correction the rule of intercalation is as follows:—

Every year the number of which is divisible by 4 is a leap year; excepting the last year of each century, which is a leap year only when the number of the century is divisible by 4: but 4000, and its multiples, 8000, 12,000, 16,000, &c. are common years. Thus the uniformity of the intercalation, by continuing to depend on the number four, is preserved, and by adopting the last correction the commencement of the year would not vary more than a day from its present place in a thousand centuries.

In order to discover whether the coincidence of the civil and solar year could not be restored in shorter periods by a different method of intercalation, we may proceed as follows:—The fraction 0.242241, which expresses the excess of the solar year above a whole number of days, being converted into a continued fraction, becomes

$$\cfrac{1}{4+\cfrac{1}{7+\cfrac{1}{1+\cfrac{1}{4+\cfrac{1}{7+\cfrac{1}{1+,\ \&c.}}}}}}$$

which gives the series of approximating fractions,

$$\frac{1}{4},\ \frac{7}{29},\ \frac{8}{33},\ \frac{39}{161},\ \frac{281}{1160},\ \frac{320}{1321}.$$

The first of these gives the Julian intercalation of one day in four years, and is considerably too great. It supposes the year to contain 365 days 6 hours.

The second gives seven intercalary days in twenty-nine years, and errs in defect, as it supposes a year of 365 d. 5 h. 47 min. 35 sec.

The third gives eight intercalations in thirty-three years, or seven successive intercalations at the end of four years respectively, and the eighth at the end of five years. This supposes the year to contain 365 d. 5 h. 49. min. 5·45 sec.

The fourth fraction, $\frac{39}{161} = \frac{32+7}{132+29} = \frac{4 \times 8 + 7}{4 \times 33 + 29}$, combines four periods of thirty-three years with one of twenty-nine, and would consequently be very inconvenient in application. It supposes the year to consist of 365 d. 5 h. 48 min. 49·19 sec.

The fifth gives 281 intercalary days in 1160 years, and supposes a year of 365 d. 5 h. 49·19 sec.

The sixth, $\frac{320}{1321} = \frac{960}{3963}$, gives 960 intercalary days in 3963 years, whereas the Gregorian rule gives 961 in that time. It gives a year of 365 d. 5 h. 48 min. 49·59 sec., differing from the true solar year only by three-hundredths of a second.

The fraction $\frac{8}{33}$ offers a convenient and very accurate method of intercalation. It implies a year differing in excess from the true year only by 15·38 seconds, while the Gregorian year is too long by 25·38 seconds. In a period of thirty-three years, therefore, it produces a nearer coincidence between the civil and solar years than the Gregorian method in 400 years; and, by reason of its shortness, confines the evagations of the mean equinox from the true within much narrower limits. It has been stated by Scaliger, Weidlar, Montucla, and others, that the modern Persians actually follow this method, and intercalate eight days in thirty-three years. The statement has, however, been contested on good authority; and it seems proved (see Delambre, *Astronomie Moderne*, tom. i. p. 81) that the Persian intercalation combines the two periods $\frac{7}{29}$ and $\frac{8}{33}$. If they follow the combination $\frac{7+4\times 8}{29+4\times 33} = \frac{39}{161}$, their determination of the length of the tropical year has been extremely exact. The discovery of the period of thirty-three years is ascribed to Omar Cheyam, one of the eight astronomers appointed by Gelal-Eddin Malech Schah, sultan of Khorassan, to reform or construct a calendar, about the year 1079 of our era.

If the commencement of the year, instead of being retained at the same place in the seasons by a uniform method of intercalation, were made to depend on astronomical phenomena, the intercalations would succeed each other in an irregular manner, sometimes after four years and sometimes after five; and it would occasionally, though rarely indeed, happen, that it would be impossible to determine the day on which the year ought to begin. In the calendar, for example, which was attempted to be introduced in France in 1793, the beginning of the year was fixed at the midnight preceding the day in which the true autumnal equinox falls. But supposing the instant of the sun's entering into the sign Libra to be very near midnight, the small errors of the solar tables might render it doubtful to which day the equinox really belonged; and it would be in vain to have recourse to observation to obviate the difficulty. It is therefore infinitely more commodious to determine the commencement of the year by a fixed rule of intercalation; and of the various methods

which might be employed, no one, perhaps, is on the whole more easy of application, or better adapted for the purposes of computation, than the Gregorian.

Of the Lunar Year and Luni-solar Periods.—The lunar year, consisting of twelve lunar months, contains only 354 days; its commencement consequently anticipates that of the solar year by eleven days, and passes through the whole circle of the seasons in about thirty-four lunar years. It is therefore so obviously ill adapted to the computation of time, that, excepting the modern Jews and Mahommedans, almost all nations who have regulated their months by the moon have employed some method of intercalation by means of which the beginning of the year is retained at nearly the same fixed place in the seasons.

In the early ages of Greece the year was regulated entirely by the moon. Solon divided the year into twelve months, consisting alternately of twenty-nine and thirty days, the former of which were called *deficient* months, and the latter *full* months. The lunar year, therefore, contained 354 days, exceeding the exact time of twelve lunations by about 8·8 hours. The first expedient adopted to reconcile the lunar and solar years seems to have been the addition of a month of thirty days to every second year. Two lunar years would thus contain 25 months, or 738 days, while two solar years, of $365\frac{1}{4}$ days each, contain $730\frac{1}{2}$ days. The difference of $7\frac{1}{2}$ days was still too great to escape observation; it was accordingly proposed by Cleostratus of Tenedos, who flourished shortly after the time of Thales, to omit the biennary intercalation every eighth year. In fact, the $7\frac{1}{2}$ days by which two lunar years exceeded two solar years, amounted to thirty days, or a full month, in eight years. By inserting, therefore, three additional months instead of four in every period of eight years, the coincidence between the solar and lunar year would have been exactly restored if the latter had contained only 354 days, inasmuch as the period contains $354 \times 8 + 3 \times 30 = 2922$ days, corresponding with eight solar years of $365\frac{1}{4}$ days each. But the true time of 99 lunations is 2923·528 days, which exceeds the above period by 1·528 days, or thirty-six hours and a few minutes. At the end of two periods, or sixteen years, the excess is three days, and at the end of 160 years, thirty days. It was therefore proposed to employ a period of 160 years, in which one of the intercalary months should be omitted; but as this period was too long to be of any practical use, it was never generally adopted. The common practice was to make occasional corrections as they became necessary, in order to preserve the relation between the octennial period and the state of the heaven; but these corrections being left to the care of incompetent persons, the calendar soon fell into great disorder, and no certain rule was followed till a new division of the year was proposed by Meton and Euctemon, which was immediately adopted in all the states and dependencies of Greece.

The *Metonic Cycle*, which may be regarded as the *chef d'œuvre* of ancient astronomy, is a period of nineteen solar years, after which the new moons again happen on the same days of the year. In nineteen solar years there are 235 lunations, a number which, on being divided by nineteen, gives twelve lunations for each year, with seven of a remainder, to be distributed among the years of the period. The period of Meton, therefore, consisted of twelve years, containing twelve months each, and seven years containing thirteen months each; and these last formed the third, fifth, eighth, eleventh, thirteenth, sixteenth, and nineteenth years of the cycle. As it had now been discovered that the exact length of the lunation is a little more than twenty-nine and a half days, it became necessary to abandon the alternate succession of full and deficient months; and, in order to preserve a more accurate correspondence between the civil month and the lunation, Meton divided the cycle into 125 full months of thirty days, and 110 deficient months of twenty-nine days each. The number of days in the period was therefore 6940. In order to distribute the deficient months through the period in the most equable manner, the whole period may be regarded as consisting of 235 full months of thirty days, or of 7050 days, from which 110 days are to be deducted. This gives one day to be suppressed in sixty-four; so that if we suppose the months to contain each thirty days, and then omit every sixty-fourth day in reckoning from the beginning of the period, those months in which the omission takes place will be the deficient months of course.

The number of days in the period being known, it is easy to ascertain its accuracy both in respect of the solar and lunar motions. The exact length of nineteen solar years is $19 \times 365{\cdot}24224 = 6939{\cdot}60156$ days, or 6939 days 14 hours 26·275 minutes; hence the period, which is exactly 6940 days, exceeds nineteen revolutions of the sun by nine and a half hours nearly. On the other hand, the exact time of a synodic revolution of the moon is 29·5305887 days; 235 lunations, therefore, contain $235 \times 29{\cdot}5305887 = 6939{\cdot}68834$ days, or 6939 days 16 hours 31·2 minutes, so that the period exceeds 235 lunations only by seven and a half hours.

After the Metonic cycle had been in use about a century, a correction was proposed by Calippus. At the end of four cycles, or seventy-six years, the accumulation of the seven and a half hours of difference between the cycle and 235 lunations amounts to thirty hours, or one whole day and six hours. Calippus, therefore, proposed to quadruple the period of Meton, and deduct one day at the end of that time by changing one of the full months into a deficient month. The period of Calippus, therefore, consisted of three Metonic cycles of 6940 days each, and a period of 6939 days; and its error in respect of the moon, consequently, amounted only to six hours, or to one day in 304 years. This period exceeds seventy-six true solar years by fourteen hours and a quarter nearly, but coincides exactly with seventy-six Julian years; and in the time of Calippus the length of the solar year was almost universally supposed to be exactly $365\frac{1}{4}$ days. The Calippic period is frequently referred to as a date by Ptolemy.

The *Mahommedan Year*, which is regulated entirely by the moon, consists of twelve months, containing twenty-nine and thirty days alternately; and in order to preserve the correspondence between the civil month and the lunation, a method of intercalation is employed, which, in point of accuracy, could scarcely be surpassed. The moon's synodic revolution is performed in 29 days 12 hours 44 min. 2·8 sec., whereas the civil month supposes it only $29\frac{1}{2}$ days. Now the excess, which is 44 min. 2·8 sec., amounts to 8 hours 48 min. 35·6 sec. in a year, and, neglecting the seconds, to 264 hours, or eleven days, in thirty years. Hence, eleven times in thirty years one day is added to the last month; so that in a period of thirty years there are nineteen simple years of 354 days and eleven intercalary years of 355 days. The average length of the year, therefore, differs from twelve lunations only by 35·6 seconds. The eleven intercalary years are the second, fifth, seventh, tenth, thirteenth, sixteenth, eighteenth, twenty-first, twenty-fourth, twenty-sixth, and twenty-ninth, of each cycle of thirty years.

For an account of the year adopted by the Jews, Chinese, Indians, and some other nations, and of the correspondence of their eras and epochs with those employed by Europeans, the reader may consult the article CHRONOLOGY.

Ecclesiastical Calendar.—The ecclesiastical calendar, which is adopted in all the Catholic, and most of the Pro-

testant countries of Europe, is luni-solar, being regulated partly by the solar, and partly by the lunar year; a circumstance which gives rise to the distinction between the movable and immovable feasts. So early as the second century of our era, great disputes had arisen among the Christians respecting the proper time of celebrating Easter, which governs all the other movable feasts. The Jews celebrated their passover on the 14th day of the *first month*, that is to say, the lunar month of which the fourteenth day either falls on, or next follows, the day of the vernal equinox. Most Christian sects agreed that Easter should be celebrated on a Sunday. Others followed the example of the Jews, and adhered to the 14th of the moon; but these, as usually happened to the minority, were accounted heretics, and received the appellation of Quarto-decimantes. In order to terminate dissensions, which produced both scandal and schism in the church, the council of Nice, which was held in the year 325, ordained that the celebration of Easter should thenceforth always take place on the Sunday which immediately follows the full moon that happens upon, or next after, the day of the vernal equinox. Should the fourteenth of the moon, which is regarded as the day of full moon, happen on a Sunday, the celebration of Easter was deferred to the Sunday following, in order to avoid concurrence with the Jews and the above-mentioned heretics. The observance of this rule renders it necessary to reconcile three periods which have no common measure, namely, the week, the lunar month, and the solar year; and as this can only be done approximately, and within certain limits, the determination of Easter is an affair of considerable nicety and complication. It is to be regretted that the reverend fathers who formed the council of Nice were not advised to abandon the moon altogether, and appoint Easter to be celebrated on the first or second Sunday of April. The ecclesiastical calendar would in this case have possessed all the simplicity and uniformity of the civil calendar, which only requires the adjustment of the civil to the solar year; but they were probably not sufficiently versed in astronomy to be aware of the practical difficulties which their regulation had to encounter.

Dominical Letter.—The first problem which the construction of the calendar presents is to connect the week with the year, or to find the day of the week corresponding to a given day of any year of the era. As the number of days in the week and the number in the year are prime to one another, two successive years cannot begin with the same day; for if a common year begins, for example, with Sunday, the following year will begin with Monday, and if a leap year begins with Sunday, the year following will begin with Tuesday. For the sake of greater generality, the days of the week are denoted by the first seven letters of the alphabet, A, B, C, D, E, F, G, which are placed in the calendar beside the days of the year, so that A stands opposite the first day of January, B opposite the second, and so on to G, which stands opposite the seventh; after which A returns to the eighth, and so on through the 365 days of the year. Now, if one of the days of the week, Sunday for example, is represented by E, Monday will be represented by F, Tuesday by G, Wednesday by A, and so on; and every Sunday through the year will have the same character E, every Monday F, and so with regard to the rest. The letter which denotes Sunday is called the *Dominical Letter*, or the *Sunday Letter;* and when the dominical letter of the year is known, the letters which respectively correspond to the other days of the week become known at the same time.

Solar Cycle.—In the Julian calendar the dominical letters are readily found by means of a short cycle, in which they recur in the same order without interruption The number of years in the intercalary period being four, and the days of the week being seven, their product is $4 \times 7 = 28$; twenty-eight years is therefore a period which includes all the possible combinations of the days of the week with the commencement of the year. This period is called the *Solar Cycle*, or the *Cycle of the Sun*, and restores the first day of the year to the same day of the week. At the end of the cycle the dominical letters return again in the same order on the same days of the month; hence a table of dominical letters, constructed for twenty-eight years, will serve to show the dominical letter of any given year from the commencement of the era to the reformation. The cycle, though probably not invented before the time of the council of Nice, is regarded as having commenced nine years before the era, so that the year *one* was the tenth of the solar cycle. To find the year of the cycle, we have therefore the following rule: *Add nine to the date, divide the sum by twenty-eight; the quotient is the number of cycles elapsed, and the remainder is the year of the cycle.* Should there be no remainder, the proposed year is the twenty-eighth or last of the cycle. This rule is conveniently expressed by the formula $\left(\frac{x+9}{28}\right)_r$, in which x denotes the date, and the symbol r denotes that the remainder, which arises from the division of $x+9$ by 28, is the number required. Thus, for 1840, we have $\frac{1840+9}{28} = 66\frac{1}{28}$, therefore $\left(\frac{1840+9}{28}\right)_r = 1$, and the year 1840 is the first of the solar cycle.

In order to make use of the solar cycle in finding the dominical letter, it is necessary to know that the first year of the Christian era began with Saturday. The dominical letter of that year, which was the tenth of the cycle, was consequently B. The following year, or the 11th of the cycle, the letter was A; then G. The fourth year was bissextile, and the dominical letters were F, E; the following year D, and so on. In this manner it is easy to find the dominical letter belonging to each of the twenty-eight years of the cycle. But at the end of a century the order is interrupted in the Gregorian calendar by the secular suppression of the leap year; hence the cycle can only be employed during a century. In the reformed calendar the intercalary period is four hundred years, which number being multiplied by seven, gives two thousand eight hundred years as the interval in which the coincidence is restored between the days of the year and the days of the week. This long period, however, may be reduced to four hundred years; for since the dominical letter goes back five places every four years, its variation in four hundred years, in the Julian calendar, was five hundred places, which is equivalent to only three places (for five hundred divided by seven leaves three); but the Gregorian calendar suppresses exactly three intercalations in four hundred years, so that after four hundred years the dominical letters must again return in the same order.

Hence the following table of dominical letters for four hundred years will serve to show the dominical letter of any year in the Gregorian calendar for ever. It contains four columns of letters, each column serving for a century. In order to find the column from which the letter in any given case is to be taken, strike off the two last figures of the date, divide the preceding figures by four, and the remainder will indicate the column. The symbol X, employed in the formula at the top of the column, denotes the date after the two last figures have been suppressed. For example, required the dominical letter of the year 1839? In this case $X = 18$, therefore $\left(\frac{X}{4}\right)_r = 2$; and in the second column of letters, opposite 39, we find F, which is the letter of the proposed year.

TABLE I.—*Dominical Letters.*

Years of the Century.	$\left(\frac{X}{4}\right)_r=1$	$\left(\frac{X}{4}\right)_r=2$	$\left(\frac{X}{4}\right)_r=3$	$\left(\frac{X}{4}\right)_r=0$
	C	E	G	B, A
1 29 57 85	B	D	F	G
2 30 58 86	A	C	E	F
3 31 59 87	G	B	D	E
4 32 60 88	F, E	A, G	C, B	D, C
5 33 61 89	D	F	A	B
6 34 62 90	C	E	G	A
7 35 63 91	B	D	F	G
8 36 64 92	A, G	C, B	E, D	F, E
9 37 65 93	F	A	C	D
10 38 66 94	E	G	B	C
11 39 67 95	D	F	A	B
12 40 68 96	C, B	E, D	G, F	A, G
13 41 69 97	A	C	E	F
14 42 70 98	G	B	D	E
15 43 71 99	F	A	C	D

27 55 83	E	G	B	C
28 56 84	D, C	F, E	A, G	B, A

It deserves to be remarked, that as the dominical letter of the first year of the era was B, the first column of the above table will give the dominical letter of every year from the commencement of the era to the reformation. For this purpose divide the date by 28, and the letter opposite the remainder, in the first column of figures, is the dominical letter of the year. For example, suppose the date to be 1148. On dividing this number by 28, the remainder is 0, or 28; and opposite 28, in the first column of letters, we find D, C, which, therefore, are the dominical letters of the year 1148.

Lunar Cycle and Golden Number.—In connecting the lunar month with the solar year, the framers of the ecclesiastical calendar adopted the period of Meton, which they supposed to be exact. A different arrangement has, however, been followed with respect to the distribution of the months. The lunations are supposed to consist of twenty-nine and thirty days alternately, or the lunar year of 354 days; and in order to make up nineteen solar years, six embolismic or intercalary months, of thirty days each, are introduced in the course of the cycle, and one of twenty-nine days at the end. This gives $19 \times 354 + 6 \times 30 + 29 = 6935$ days, to be distributed among 235 lunar months. But every leap year one day must be added to the lunar month in which the 29th of February is included. Now, if leap year happens on the first, second, or third year of the period, there will be five leap years in the period, but only four when the first leap year falls on the fourth. In the former case the number of days in the period becomes 6940, and in the latter 6939. The mean length of the cycle is therefore $6939\frac{3}{4}$ days, agreeing exactly with nineteen Julian years.

By means of the lunar cycle the new moons of the calendar were indicated before the reformation. As the cycle restores these phenomena to the same days of the civil month, they will fall on the same days in any two years which occupy the same place in the cycle; consequently a table of the moon's phases for 19 years will serve for any year whatever when we know its number in the cycle. This number is called the *Golden Number*, either because it was so termed by the Greeks, or because it was usual to mark it with red letters in the calendar. The Golden Numbers were introduced into the calendar about the year 530, but disposed as they would have been if they had been inserted at the time of the council of Nice. The cycle is supposed to commence with the year in which the new moon falls on the 1st of January, which took place the year preceding the commencement of our era. Hence, to find the Golden Number N, we have $N = \left(\frac{x+1}{19}\right)_r$, which gives the following rule: *Add* 1 *to the date, divide the sum by* 19; *the quotient is the number of cycles elapsed, and the remainder is the Golden Number.* When the remainder is 0, the proposed year is of course the last or 19th of the cycle. It ought to be remarked that the new moons, determined in this manner, may differ from the astronomical new moons sometimes so much as two days. The reason is, that the sum of the solar and lunar inequalities, which are compensated in the whole period, may amount in certain cases to 10°, and thereby cause the new moon to arrive on the second day before or after its mean time.

Dionysian Period.—The cycle of the sun brings back the days of the month to the same day of the week; the lunar cycle restores the new moons to the same day of the month; therefore $28 \times 19 = 532$ years, includes all the variations in respect of the new moons and the dominical letters, and is consequently a period after which the new moons again occur on the same day of the month and the same day of the week. This is called the *Dionysian* or *Great Paschal period*, from its having been employed by Dionysius Exiguus, familiarly styled *Denys the Little*, in determining Easter Sunday. It was however first proposed by Victorius of Aquitain, who had been appointed by Pope Hilary to revise and correct the church calendar. Hence it is also called the Victorian period. It continued in use till the Gregorian reformation.

Cycle of Indiction.—Besides the solar and lunar cycles, there is a third of 15 years, called the cycle of indiction, frequently employed in the computations of chronologists. This period is not astronomical, like the two former; but has reference to certain judicial acts which took place at stated epochs under the Greek emperors. Its commencement is referred to the 1st of January of the year 313 of the common era. By extending it backwards, it will be found that the first of the era was the fourth of the cycle of indiction. The number of any year in this cycle will therefore be given by the formula $\left(\frac{x+3}{15}\right)_r$, that is to say, *add* 3 *to the date, divide the sum by* 15, *and the remainder is the year of the indiction.* When the remainder is 0, the proposed year is the fifteenth of the cycle.

Julian Period.—The Julian period, proposed by the celebrated Joseph Scaliger as an universal measure of chronology, is formed by taking the continued product of

the three cycles of the sun, of the moon, and of the indiction, and is consequently $28 \times 19 \times 15 = 7980$ years. In the course of this long period no two years can be expressed by the same numbers in all the three cycles. Hence, when the number of any proposed year in each of the cycles is known, its number in the Julian period can be determined by the resolution of a very simple problem of the indeterminate analysis. It is unnecessary, however, in the present case, to exhibit the general solution of the problem, because when the number in the period corresponding to any one year in the common era has been ascertained, it is easy to establish the correspondence for all other years, without having again recourse to the direct solution of the problem. We shall therefore find the number of the Julian period corresponding to the first of our era.

We have already seen that the year 1 of the era had 10 for its number in the solar cycle, 2 in the lunar cycle, and 4 in the cycle of indicti n; the question is therefore to find a number such, that when it is divided by the three numbers 28, 19, and 15 respectively, the three quotients shall be 10, 2, and 4.

Let x, y, and z, be the three quotients of the divisions; the number sought will then be expressed by $28\,x + 10$, by $19\,y + 2$, or by $15\,z + 4$. Hence the two equations

$$28\,x + 10 = 19\,y + 2 = 15\,z + 4.$$

To resolve the equation $28\,x + 10 = 19\,y + 2$, or $y = x + \frac{9\,x + 8}{19}$, let $m = \frac{9\,x + 8}{19}$, we have then $x = 2\,m + \frac{m - 8}{9}$. Let $\frac{m - 8}{9} = m'$; then $m = m' + 8$; hence $x = 18\,m' + 16 + m' = 19\,m + 16$..........(1)

Again, since $28\,x + 10 = 15\,z + 4$, we have $15\,z = 28\,x + 6$, or $z = 2\,x - \frac{2\,x - 6}{15}$. Let $\frac{2\,x - 6}{15} = n$; then $2\,x = 15\,n + 6$, and $x = 7\,n + 3 + \frac{n}{2}$. Let $\frac{n}{2} = n'$; then $n = 2\,n'$; consequently

$$x = 14\,n' + 3 + n' = 15\,n' + 3 \text{.........(2)}$$

Equating the above two values of x, we have $15\,n' + 3 = 19\,m' + 16$; whence $n' = m' + \frac{4\,m' + 13}{15}$. Let $\frac{4\,m' + 13}{15} = p$; we have then $4\,m' = 15\,p - 13$, and $m' = 4\,p - \frac{p + 13}{4}$. Let $\frac{p + 13}{4} = p'$; then $p = 4\,p' - 13$; whence $m' = 16\,p' - 52 - p' = 15\,p' - 52$. Now in this equation p' may be any number whatever, provided $15\,p'$ exceed 52. The smallest value of p' (which is the one here wanted) is therefore 4; for $15 \times 4 = 60$. Assuming therefore $p' = 4$, we have $m' = 60 - 52 = 8$; and consequently, since $x = 19\,m' + 15$, $x = 19 \times 8 + 16 = 168$. The number required is consequently $20 \times 168 + 10 = 4714$.

Having found the number 4714 for the first of the era, the correspondence of the years of the era and of the period is as follows:

Era, 1, 2, 3,... x,
Period, 4714, 4715, 4716,...$4713 + x$;

from which it is evident, that if we take P to represent the year of the Julian period, and Y the corresponding year of the Christian era, we shall have

$$P = 4713 + Y, \text{ and } Y = P - 4713.$$

With regard to the numeration of the years previous to the commencement of the era, the practice is not uniform. Chronologists, in general, reckon the year preceding the first of the era -1, the next preceding -2, and so on. In this case

Era, -1, -2, -3,... $-x$,
Period, 4713, 4712, 4711,...$4714 - x$;

whence

$$P = 4714 - Y, \text{ and } Y = 4714 - P.$$

But astronomers, in order to preserve the uniformity of computation, make the series of years proceed without interruption, and reckon the year preceding the first of the era 0. In this case

Era, 0, -1, -2,... $-x$,
Period, 4713, 4712, 4711,...$4714 - x$;

therefore

$$P = 4713 - Y, \text{ and } Y = 4713 - P.$$

Reformation of the Calendar.—The ancient church calendar was founded on two suppositions, both erroneous, namely, that the year contains $365\frac{1}{4}$ days, and that 235 lunations are exactly equal to nineteen solar years. It could not therefore long continue to preserve its correspondence with the seasons, or to indicate the days of the new moons with the same accuracy. About the year 730, the venerable Bede had already perceived the anticipation of the equinoxes, and remarked that these phenomena then took place about three days earlier than at the time of the council of Nice. Five centuries after the time of Bede, the divergence of the true equinox from the 21st of March, which now amounted to seven or eight days, was pointed out by John of Sacrobosco, in a work published under the title *De Anni Ratione;* and by Roger Bacon, in a treatise *De Reformatione Calendarii*, which, though never published, was transmitted to the pope. These works were probably little regarded at the time; but as the errors of the calendar went on increasing, and the true length of the year, in consequence of the progress of astronomy, became better known, the project of a reformation was again revived in the fifteenth century; and in 1474 Pope Sextus IV. invited Regiomontanus, the most celebrated astronomer of the age, to Rome, to superintend the reconstruction of the calendar. The premature death of Regiomontanus caused the design to be suspended for the present: but in the following century numerous memoirs appeared on the subject, among the authors of which were Stœffler, Albert Pighius, John Schœner, Lucas Gauricus, and other mathematicians of celebrity. At length Pope Gregory XIII. perceiving that the measure was likely to confer a great eclat on his pontificate, undertook the long-desired reformation; and having found the governments of the principal catholic states ready to adopt his views, he issued a brief in the month of March 1582, in which he abolished the use of the ancient calendar, and substituted that which has since been received in almost all Christian countries under the name of the *Gregorian Calendar* or *New Style.* The author of the system adopted by Gregory was Aloysius Lilius, or Luigi Lilio Ghiraldi, a learned astronomer and physician of Naples, who died, however, before its introduction; but the individual who most contributed to give the ecclesiastical calendar its present form, and who was charged with all the calculations necessary for its verification, was Clavius, by whom it was completely developed and explained in a great folio treatise of 800 pages, published in 1603, the title of which is given at the end of this article.

It has already been mentioned that the error of the Julian year was corrected in the Gregorian calendar by the suppression of three intercalations in 400 years. In order to restore the commencement of the year to the same place in the seasons that it had occupied at the time of the council of Nice, Gregory directed the day following the feast of St Francis, that is to say the 5th of October, to be reckoned the 15th of that month. By this regulation

 the vernal equinox, which now happened on the 11th of March, was restored to the 21st. From 1582 to 1700, the difference between the old and new style continued to be ten days; but 1700 being a leap year in the Julian calendar, and a common year in the Gregorian, the difference of the styles during the eighteenth century was eleven days. The year 1800 was also common in the new calendar, and, consequently, the difference in the present century is twelve days. From 1900 to 2100 it will be thirteen days.

The restoration of the equinox to its former place in the year, and the correction of the intercalary period, were attended with no difficulty; but Lilius had also to adapt the lunar year to the new rule of intercalation. The lunar cycle contained 6939 days 18 hours, whereas the exact time of 235 lunations, as we have already seen, is $235 \times 29{\cdot}5305887 = 6939$ days 16 hours 31·2 minutes. The difference, which is 1 hour 28·8 minutes, amounts to a day in 308 years, so that at the end of this time the new moons occur one day earlier than they are indicated by the golden numbers. During the 1257 years that elapsed between the council of Nice and the reformation, the error had accumulated to four days, so that the new moons, which were marked in the calendar as happening, for example, on the 5th of the month, actually fell on the first. It would have been easy to correct this error by placing the golden numbers four lines higher in the new calendar; and the suppression of the ten days had already rendered it necessary to place them ten lines lower, and to carry those which belonged, for example, to the 5th and 6th of the month, to the 15th and 16th. But, supposing this correction to have been made, it would have again become necessary, at the end of 308 years, to advance them one line higher, in consequence of the accumulation of the error of the cycle to a whole day. On the other hand, as the golden numbers were only adapted to the Julian calendar, every omission of the centenary intercalation would require them to be placed one line lower, opposite the 6th, for example, instead of the 5th of the month; so that, generally speaking, the places of the golden numbers would have to be changed every century. On this account Lilius thought fit to reject the golden numbers from the calendar, and supply their place by another set of numbers called *Epacts*, the use of which we shall now proceed to explain.

Epacts.—Epact is a word of Greek origin, employed in the calendar to signify the moon's age at the end of the year. The common solar year containing 365 days, and the lunar year only 354 days, the difference is eleven; whence, if a new moon fall on the 1st of January in any year, the moon will be eleven days old on the first day of the following year, and twenty-two days on the first of the third year. The numbers eleven and twenty-two are therefore the epacts of those years respectively. Another addition of eleven gives thirty-three for the epact of the fourth year; but in consequence of the insertion of the intercalary month in each third year of the lunar cycle, this epact is reduced to three. In like manner the epacts of all the following years of the cycle are obtained by successively adding eleven to the epact of the former year, and rejecting thirty as often as the sum exceeds that number. They are therefore connected with the golden numbers by the formula $\left(\frac{11\ n}{30}\right)_r$, in which n is any whole number; and for a whole lunar cycle (supposing the first epact to be 11), they are as follows: 11, 22, 3, 14, 25, 6, 17, 28, 9, 20, 1, 12, 23, 4, 15, 26, 7, 18, 29. But the order is interrupted at the end of the cycle; for the epact of the following year, found in the same manner, would be $29 + 11 = 40 = 10$, whereas it ought again to be 11 to correspond with the moon's age and the golden number 1. The reason of this is, that the intercalary month, inserted at the end of the cycle, contains only twenty-nine days instead of thirty; whence, after 11 has been added to the epact of the year corresponding to the golden number 19, we must reject twenty-nine instead of thirty, in order to have the epact of the succeeding year; or, which comes to the same thing, we must add twelve to the epact of the last year of the cycle, and then reject thirty as before.

This method of forming the epacts might have been continued indefinitely if the Julian intercalation had been followed without correction, and the cycle been perfectly exact; but as neither of these suppositions is true, two equations or corrections must be applied, one depending on the error of the Julian year, which is called the solar equation; the other on the error of the lunar cycle, which is called the lunar equation. The solar equation occurs three times in 400 years, namely, in every secular year which is not a leap year; for in this case the omission of the intercalary day causes the new moons to arrive one day later in all the following months, so that the moon's age at the end of the month is one day less than it would have been if the intercalation had been made, and the epacts must accordingly be all diminished by unity. Thus the epacts 11, 22, 3, 14, &c. become 10, 21, 2, 13, &c. On the other hand, when the time by which the new moons anticipate the lunar cycle amounts to a whole day, which, as we have seen, it does in 308 years, the new moons will arrive one day earlier, and the epacts must consequently be increased by unity. Thus the epacts 11, 22, 3, 14, &c. in consequence of the lunar equation, become 12, 23, 4, 15, &c. In order to preserve the uniformity of the calendar, the epacts are changed only at the commencement of a century; the correction of the error of the lunar cycle is therefore made at the end of 300 years. In the Gregorian calendar this error is assumed to amount to one day in $312\frac{1}{2}$ years, or eight days in 2500 years, an assumption which requires the line of epacts to be changed seven times successively at the end of each period of 300 years, and once at the end of 400 years; and, from the manner in which the epacts were disposed at the reformation, it was found most correct to suppose one of the periods of 2500 years to terminate with the year 1800.

The years in which the solar equation occurs, counting from the reformation, are 1700, 1800, 1900, 2100, 2200, 2300, 2500, &c. Those in which the lunar equation occurs are 1800, 2100, 2400, 2700, 3000, 3300, 3600, 3900, after which, 4300, 4600, and so on. When the solar equation occurs, the epacts are diminished by unity; when the lunar equation occurs, the epacts are augmented by unity; and when both equations occur together, as in 1800, 2100, 2700, &c. they compensate each other, and the epacts are not changed.

In consequence of the solar and lunar equations, it is evident that the epact, or moon's age at the beginning of the year, must, in the course of centuries, have all different values from one to thirty inclusive, corresponding to the days in a full lunar month. Hence, for the construction of a perpetual calendar, there must be thirty different sets or lines of epacts. These are exhibited in the subjoined table (Table II.), called the *Extended Table of Epacts*, which is constructed in the following manner. The series of golden numbers is written in a line at the top of the table, and under each golden number is a column of thirty epacts, arranged in the order of the natural numbers, beginning at the bottom and proceeding to the top of the column. The first column, under the golden number 1, contains the epacts 1, 2, 3, 4, &c. to 30 or 0. The second column, corresponding to the following year in the lunar cycle, must have all its epacts augmented by 11; the low-

est number therefore in the column is 12, then 13, 14, 15, and so on. The third column, corresponding to the golden number 3, has for its first epact 12 + 11 = 23; and in the same manner all the nineteen columns of the table are formed. Each of the thirty lines of epacts is designated by a letter of the alphabet, which serves as its index or argument. The order of the letters, like that of the numbers, is from the bottom of the column upwards.

TABLE II.—*Extended Table of Epacts.*

In the tables of the church calendar the epacts are usually printed in Roman numerals, excepting the last, which is designated by an asterisk (*), used as an indefinite symbol to denote 30 or 0; and 25, which in the eight last columns is expressed in Arabic characters, for a reason that will immediately be explained. In the table here given, this distinction is made by means of an accent placed over the last figure.

At the reformation the epacts were given by the line D. The year 1600 was a leap year; the intercalation accordingly took place as usual, and there was no interruption in the order of the epacts; the line D was employed till 1700. In that year the omission of the intercalary day rendered it necessary to diminish the epacts by unity, or to pass to the line C. In 1800 the solar equation again occurred, in consequence of which it was necessary to descend one line to have the epacts diminished by unity; but in this year the lunar equation also occurred, the anticipation of the new moons having amounted to a day; the new moons accordingly happened a day earlier, which rendered it necessary to take the epacts in the next higher line. There was consequently no alteration; the two equations destroyed each other. The line of epacts belonging to the present century is therefore C. In 1900 the solar equation occurs, after which the line is B. The year 2000 is a leap year, and there is no alteration. In 2100 the equations again occur together and destroy each other, so that the line B will serve three centuries, from 1900 to 2200. From that year to 2300 the line will be A. In this manner the line of epacts belonging to any given century is easily found, and the method of proceeding is obvious. When the solar equation occurs alone, the line of epacts is changed to the next lower in the table; when the lunar equation occurs alone, the line is changed to the next higher; when both equations occur together, no change takes place. In order that it may be perceived at once to what centuries the different lines of epacts respectively belong, we have placed them in a column on the left hand side of the above table.

The use of the epacts is to show the days of the new moons, and consequently the moon's age on any day of the year. For this purpose they are placed in the calendar

(Table III.) along with the days of the month and dominical letters, in a retrograde order, so that the asterisk stands beside the 1st of January, 29 beside the 2d, 28 beside the 3d, and so on to 1, which corresponds to the 30th. After this comes the asterisk, which corresponds to the 31st of January, then 29, which belongs to the 1st of February, and so on to the end of the year. The reason of this distribution is evident. If the last lunation of any year ends, for example, on the 2d of December, the new moon falls on the 3d; and the moon's age on the 31st, or at the end of the year, is twenty-nine days. The epact of the following year is therefore twenty-nine. Now that lunation having commenced on the 3d of December, and consisting of thirty days, will end on the 1st of January. The 2d of January is therefore the day of the new moon, which is indicated by the epact twenty-nine. In like manner, if the new moon fell on the 4th of December, the epact of the following year would be twenty-eight, which, to indicate the day of next new moon, must correspond to the 3d of January.

Calendar.

When the epact of the year is known, the days on which the new moons occur throughout the whole year are shown by this table, which is called the *Gregorian Calendar of Epacts*. For example, the epact of the year 1832, as found in Table II., is twenty-eight. This epact occurs at the 3d of January, the 2d of February, the 3d of March, the 2d of April, the 1st of May, &c.; and these days are consequently the days of the ecclesiastical new moons in 1832. The astronomical new moons generally take place one or two days, sometimes even three days, earlier than those of the calendar.

There are some artifices employed in the construction of this table, to which it is necessary to pay attention. The thirty epacts correspond to the thirty days of a full lunar month; but the lunar months consist of twenty-nine and thirty days alternately; therefore in six months of the year the thirty epacts must correspond only to twenty-nine days. For this reason the epacts twenty-five and twenty-four are placed together, so as to belong only to one day in the months of February, April, June, August, September, and November, and in the same months another 25 is distinguished by an accent, or by being printed in a dif-

ferent character, is placed beside 26, and belongs to the same day. The reason for doubling the 25 was to prevent the new moons from being indicated in the calendar as happening twice on the same day in the course of the lunar cycle, a thing which actually cannot take place. For example, if we observe the line B in Table II., we shall see that it contains both the epacts twenty-four and twenty-five, so that if these correspond to the same day of the month, two new moons would be indicated as happening on that day within nineteen years. Now the three epacts 24, 25, 26, can never occur in the same line; therefore in those lines in which 24 and 25 occur, the 25 is accented, and placed in the calendar beside 26. When 25 and 26 occur in the same line of epacts, the 25 is not accented, and in the calendar stands beside 24. The lines of epacts in which 24 and 25 both occur, are those which are marked by one of the eight letters *b*, *e*, *k*, *n*, *r*, B, E, N, in all of which 25′ stands in a column corresponding to a golden number higher than 11. There are also eight lines in which 25 and 26 occur, namely, *c*, *f*, *l*, *p*, *s*, C, F, P. In the other 14 lines, 25 either does not occur at all, or it occurs in a line in which neither 24 nor 26 is found. From this it appears, that if the golden number of the year exceeds 11, the epact 25, in six months of the year, must correspond to the same day in the calendar as 26; but if the golden number does not exceed 11, that epact must correspond to the same day as 24. Hence the reason for distinguishing 25 and 25′. In using the calendar, if the epact of the year is 25, and the golden not above 11, take 25; but if the golden number exceeds 11, take 25′.

Another peculiarity requires explanation. The epact 19′ (also distinguished by an accent or different character) is placed in the same line with 20 at the 31st of December. It is, however, only used in those years in which the epact 19 concurs with the golden number 19. When the golden number is 19, that is to say, in the last year of the lunar cycle, the supplementary month contains only 29 days. Hence, if in that year the epact should be 19, a new moon would fall on the 2d of December, and the lunation would terminate on the 30th, so that the next new moon would arrive on the 31st. The epact of the year, therefore, or 19, must stand beside that day, whereas, according to the regular order, the epact corresponding to the 31st of December is 20; and this is the reason for the distinction.

As an example of the use of the preceding tables, suppose it were required to determine the moon's age on the 10th of April 1832. In 1832 the golden number is $\left(\frac{1832+1}{19}\right)_r = 9$, and the line of epacts belonging to the century is C. In Table II. under 9, and in the line C, we find the epact 28. In the calendar, Table III. look for April, and the epact 28 is found opposite the second day. The 2d of April is therefore the first day of the moon, and the 10th is consequently the ninth day of the moon. Again, suppose it were required to find the moon's age on the 2d of December in the year 1916. In this case the golden number is $\left(\frac{1916+1}{19}\right)_r = 17$, and the line of epacts is B. Under 17, in line B, the epact is 25. In the calendar this epact first occurs before the 2d of December at the 26th of November. The 26th of November is consequently the first day of the moon, and the 2d of December is therefore the seventh day.

Easter.—The next, and indeed the principal use of the calendar, is to find Easter, which, according to the regulation of the council of Nice, must be determined from the following conditions: First, Easter must be celebrated on a Sunday; second, this Sunday must *follow* the 14th day of the paschal moon, so that if the 14th of the paschal moon falls on a Sunday, then Easter must be celebrated on the Sunday following; third, the paschal moon is that of which the 14th day falls on or next follows the day of the vernal equinox; fourth, the equinox is fixed invariably in the calendar on the 21st of March.

From these conditions it follows, that the paschal full moon, or the 14th of the paschal moon, cannot happen before the 21st of March, and that Easter in consequence cannot happen before the 22d of March. If the 14th of the moon falls on the 21st, the new moon must fall on the 8th; for $21 - 13 = 8$; and the paschal new moon cannot happen before the 8th; for suppose the new moon to fall on the 7th, then the full moon would arrive on the 20th, or the day before the equinox. The following moon would be the paschal moon. But the fourteenth of this moon falls at the latest on the 18th of April, or 29 days after the 20th of March; for by reason of the double epact that occurs at the 4th and 5th of April, this lunation has only 29 days. Now, if in this case the 18th of April is Sunday, then Easter must be celebrated on the following Sunday, or the 25th of April. Hence Easter Sunday cannot happen earlier than the 22d of March, or later than the 25th of April.

Hence we derive the following rule for finding Easter Sunday from the tables. 1*st*, Find from Table II. the epact of the proposed year. 2*d*, Find in the calendar (Table III.) the first day after the 7th of March, which corresponds to the epact of the year; this will be the first day of the paschal moon. 3*d*, Reckon thirteen days after that of the first of the moon; the following will be the fourteenth of the moon, or the day of the full paschal moon. 4*th*, Find from Table I. the dominical letter of the year, and observe in the calendar the first day after the fourteenth of the moon, which corresponds to the dominical letter; this will be Easter Sunday.

Example.—Required the day on which Easter Sunday falls in the year 1840? 1*st*, For this year the golden number is $\left(\frac{1840+1}{19}\right)_r = 17$, and the epact (Table II. line C) is 26. 2*d*, After the 7th of March the epact 26 first occurs in Table III. at the 4th of April, which therefore is the day of the new moon. 3*d*, Since the new moon falls on the 4th, the full moon is on the 17th ($4 + 13 = 17$). 4*th*, The dominical letters of 1840 are E, D (Table I.), of which D must be taken, as E belongs only to January and February. After the 17th of April D first occurs in the calendar (Table III.) at the 19th. Therefore, in 1840, Easter Sunday falls on the 19th of April.

Such is the very complicated and artificial, though highly ingenious method, invented by Lilius, for the determination of Easter and the other movable feasts. Its principal, though perhaps least obvious advantage, consists in its being entirely independent of astronomical tables, or indeed of any celestial phenomena whatever; so that all chances of disagreement arising from the inevitable errors of tables, or the uncertainty of observation, are avoided, and Easter determined without the possibility of mistake. But this advantage is only procured by the sacrifice of some accuracy: for notwithstanding the cumbersome apparatus employed, the conditions of the problem are not always exactly satisfied, nor is it possible that they can be always satisfied by any similar method of proceeding. The equinox is fixed on the 21st of March, though the sun enters Aries generally on the 20th of that month, sometimes even on the 19th. It is therefore quite possible that a full moon may arrive after the true equinox, and yet precede the 21st of March. This therefore would not be the paschal moon of the calendar, though it undoubtedly ought to be so, if the intention of the council of Nice were rigidly fol-

 lowed. The new moons indicated by the epacts also differ from the astronomical new moons, and even from the mean new moons, in general by one or two days. In imitation of the Jews, who counted the time of the new moon, not from the moment of the actual phase, but from the time the moon first became visible after the conjunction, the fourteenth day of the moon is regarded as the full moon; but the moon is in opposition generally on the 16th day; therefore, when the new moons of the calendar nearly concur with the true new moons, the full moons are considerably in error. The epacts are also placed so as to indicate the full moons generally one or two days after the true full moons; but this was done purposely, to avoid the chance of concurring with the Jewish passover, which the framers of the calendar seem to have considered a greater evil than that of celebrating Easter a week too late.

We will now show in what manner this whole apparatus of methods and tables may be dispensed with, and the Gregorian calendar reduced to a few simple formulæ of easy computation. And, first, to find the dominical letter.

Let L denote the number of the dominical letter of any given year of the era. Then, since every year which is not a leap year ends with the same day as that with which it began, the dominical letter of the following year must be $(L - 1)$, retrograding one letter every common year. After x years, therefore, the number of the letter will be $(L - x)$. But as L can never exceed 7, the number x will always exceed L after the first seven years of the era. In order therefore to render the subtraction possible, L must be increased by some multiple of 7, as $7m$, and the formula then becomes $(7m + L - x)$. In the year preceding the first of the era, the dominical letter was C; for that year, therefore, we have $L = 3$; consequently for any succeeding year x, $L = (7m + 3 - x)$, the years being all supposed to consist of 365 days. But every fourth year is a leap year, and the effect of the intercalation is to throw the dominical letter one place farther back. The above expression must therefore be diminished by the number of units in $\frac{x}{4}$, or by $\left(\frac{x}{4}\right)_w$ (this notation being used to denote the quotient, *in a whole number*, that arises from dividing x by 4). Hence in the Julian calendar the dominical letter is given by the equation

$$L = 7m + 3 - x - \left(\frac{x}{4}\right)_w.$$

This equation gives the dominical letter of any year from the commencement of the era to the reformation. In order to adapt it to the Gregorian calendar, we must first add the 10 days that were left out of the year 1582; in the second place we must add one day for every century that has elapsed since 1600, in consequence of the secular suppression of the intercalary day; and lastly, we must deduct the units contained in a fourth of the same number, because every fourth centesimal year is still a leap year. Denoting therefore the number of the century (or the date after the two right-hand digits have been struck out) by c, the value of L must be increased by $10 + (c - 16) - \left(\frac{c - 16}{4}\right)_w$. We have then

$$L = 7m + 3 - x - \left(\frac{x}{4}\right)_w + 10 + (c - 16) - \left(\frac{c - 16}{4}\right)_w;$$

that is, since $3 + 10 = 13 = 6$ (the 7 days being rejected, as they do not affect the value of L),

$$L = 7m + 6 - x - \left(\frac{x}{4}\right)_w + (c - 16) - \left(\frac{c - 16}{4}\right)_w;$$

This formula is perfectly general, and easily calculated. As an example, let us take the year 1839. In this case, $x = 1839$, $\left(\frac{x}{4}\right)_w = \left(\frac{1839}{4}\right)_w = 459$, $c = 18$, $c - 16 = 2$, and $\left(\frac{c - 16}{4}\right)_w = 0$. Hence

$$L = 7m + 6 - 1839 - 459 + 2 - 0.$$
$$L = 7m - 2290 = 7 \times 328 - 2290.$$
$$L = 6 = F.$$

The year therefore begins with Monday. It will be remembered that in a leap year there are always two dominical letters, one of which is employed till the 29th of February, and the other till the end of the year. In this case, as the formula supposes the intercalation already made, the resulting letter is that which applies after the 29th of February. Before the intercalation the dominical letter had retrograded one place less. Thus for 1840 the formula gives D; during the first two months, therefore, the dominical letter is E.

In order to investigate a formula for the epact, let us make

E = the true epact of the given year;
J = the Julian epact, that is to say, the number the epact would have been if the Julian year had been still in use, and the lunar cycle had been exact;
S = the correction depending on the solar year;
M = the correction depending on the lunar cycle;

then the equation of the epact will be

$$E = J + S + M;$$

so that E will be known when the numbers J, S, and M, are determined.

The epact J depends on the golden number N, and must be determined from the fact that in 1582, the first year of the reformed calendar, N was 6, and $J = 26$. For the following years, therefore, the golden numbers and epacts are as follows:

$$\begin{aligned} &1583,\ N = 7, && J = 26 + 11 - 30 = 7; \\ &1584,\ N = 8, && J = 7 + 11 = 18; \\ &1585,\ N = 9, && J = 18 + 11 = 29; \\ &1586,\ N = 10, && J = 29 + 11 - 30 = 10; \end{aligned}$$

and in general $J = \left(\frac{26 + 11\,(N - 6)}{30}\right)_r$. But the numerator of this fraction becomes by reduction $11\,N - 40 = 11\,N - 10$ (the 30 being rejected, as the remainder only is sought) $= N + 10\,(N - 1)$; therefore, ultimately

$$J = \left(\frac{N + 10\,(N - 1)}{30}\right)_r.$$

On account of the solar equation S, the epact J must be diminished by unit every centesimal year, excepting always the fourth. After x centuries, therefore, it must be diminished by $x - \left(\frac{x}{4}\right)_w$. Now, as 1600 was a leap year, the first correction of the Julian intercalation took place in 1700; hence, taking c to denote the number of the century as before, the correction becomes $(c - 16) - \left(\frac{c - 16}{4}\right)_w$, which must be deducted from J. We have therefore

$$S = -(c - 16) + \left(\frac{c - 16}{4}\right)_w.$$

With regard to the lunar equation M, we have already stated that in the Gregorian calendar the epacts are increased by unit at the end of every period of 300 years, seven times successively, and the following increase takes place at the end of 400 years. This gives eight to be added in a period of twenty-five centuries, and $\frac{8x}{25}$ in x centuries.

Calendar.

But $\frac{8x}{25}=\frac{8x}{24}-\frac{8x}{600}=\frac{x}{3}-\frac{x}{75}=\frac{1}{3}x-\left(\frac{x}{25}\right)$. Now from the manner in which the intercalation is directed to be made (namely, seven times successively at the end of 300 years, and once at the end of 400), it is evident that the fraction $\frac{x}{25}$ must amount to unit when the number of centuries amounts to twenty-four. In like manner, when the number of centuries is $24+25=49$, we must have $\frac{x}{25}=2$; when the number of centuries is $24+2\times25=74$, then $\frac{x}{25}=3$; and, generally, when the number of centuries is $24+n\times25$, then $\frac{x}{25}=n+1$. Now this is a condition which will evidently be expressed in general by the formula $n-\left(\frac{n+1}{25}\right)_w$. Hence the correction of the epact, or the number of days to be intercalated after x centuries reckoned from the commencement of one of the periods of twenty-five centuries, is $\left\{\frac{x-\left(\frac{x+1}{25}\right)_w}{3}\right\}_w$. The last period of twenty-five centuries terminated with 1800; therefore, in any succeeding year, if c be the number of the century, we shall have $x=c-18$ and $x+1=c-17$. Let $\left(\frac{c-17}{25}\right)_w=a$, then for all years after 1800 the value of M will be given by the formula $\left(\frac{c-18-a}{3}\right)_w$; therefore, counting from the beginning of the calendar in 1582,

$$M=\left\{\frac{c-15-a}{3}\right\}_w.$$

By the substitution of these values of J, S, and M, the equation of the epact becomes

$$E=\left(\frac{N+10(N-1)}{30}\right)_r-c-16+\left(\frac{c-16}{4}\right)_w+\left(\frac{c-15-a}{3}\right)_w.$$

It may be remarked, that as $a=\left(\frac{c-17}{25}\right)_w$, the value of a will be 0 till $c-17=25$ or $c=42$; therefore, till the year 4200, a may be neglected in the computation. Had the anticipation of the new moons been taken, as it ought to have been, at one day in 308 years instead of $312\frac{1}{2}$, the lunar equation would have occurred only twelve times in 3700 years, or eleven times successively at the end of 300 years, and then at the end of 400. In strict accuracy, therefore, a ought to have no value till $c-17=37$, or $c=54$, that is to say, till the year 5400. The above formula for the epact is given by Delambre (*Hist. de l'Astronomie Moderne*, tom. i. p. 9); it may be exhibited under a variety of forms, but the above is perhaps the best adapted for calculation. Another had previously been given by Gauss, but inaccurately, inasmuch as the correction depending on a was omitted.

Having determined the epact of the year, it only remains to find Easter Sunday from the conditions already laid down. Let

P = the number of days from the 21st of March to the 15th of the paschal moon, which is the first day on which Easter Sunday can fall;

p = the number of days from the 21st of March to Easter Sunday;

L = dominical letter of the year;

l = letter belonging to the day on which the 15th of the moon falls;

then, since Easter is the Sunday following the 14th of the moon, we have

$$p=P+(L-l).$$

The value of L is always given by the formula for the dominical letter, and P and l are easily deduced from the epact, as will appear from the following considerations.

When $P=1$, the full moon is on the 21st of March, and the new moon on the eighth $(21-13=8)$, therefore the moon's age on the 1st of March (which is the same as on the 1st of January) is twenty-three days; the epact of the year is consequently twenty-three. When $P=2$ the new moon falls on the ninth, and the epact is consequently twenty-two; and, in general, when P becomes $1+x$, E becomes $23-x$, therefore $P+E=1+x+23-x=24$, and $P=24-E$. In like manner, when $P=1$, $l=D=4$; for D is the dominical letter of the calendar belonging to the 22d of March. But it is evident that when l is increased by unity, that is to say, when the full moon falls a day later, the epact of the year is diminished by unity; therefore, in general, when $l=4+x$, $E=23-x$, whence $l+E=27$ and $l=27-E$. But P can never be less than 1 nor l less than 4, and in both cases $E=23$. When, therefore, E is greater than 23, we must add 30 in order that P and l may have positive values in the formula $P=24-E$ and $l=27-E$. Hence there are two cases.

$$\text{When } E<24\ \begin{cases}P=24-E\\ l=27-E, \text{ or } \left(\frac{27-E}{7}\right)_r,\end{cases}$$

$$\text{When } E>23\ \begin{cases}P=54-E\\ l=57-E, \text{ or } \left(\frac{57-E}{7}\right)_r.\end{cases}$$

By substituting one or other of these values of P and l, according as the case may be, in the formula $p=P+(L-l)$, we shall have p, or the number of days from the 21st of March to Easter Sunday. It will be remarked, that as $(L-l)$ cannot either be 0 or negative, we must add 7 to L as often as may be necessary, in order that $(L-l)$ may be a whole positive number.

By means of the formulæ which we have now given for the dominical letter, the golden number, and the epact, Easter Sunday may be computed for any year after the reformation, without the assistance of any tables whatever. As an example, suppose it were required to compute Easter for the year 1840. By substituting this number in the formula for the dominical letter, we have $x=1840$, $c-16=2$, $\left(\frac{c-16}{4}\right)_w=0$, therefore

$$\begin{aligned}L&=7m+6-1840-460+2\\&=7m-2292\\&=7\times328-2292=2296-2292=4\\L&=4=D \ldots\ldots (1).\end{aligned}$$

For the golden number we have $N=\left(\frac{1840+1}{19}\right)_r$, therefore $N=17$ ....(2).

For the epact we have $\left(\frac{N+10(N-1)}{30}\right)_r=\left(\frac{17+160}{30}\right)_r=\left(\frac{177}{30}\right)_r=27$; likewise $c-16=18-16=2$, $\frac{c-15}{3}=1$, $a=0$, therefore

$$E=27-2+1=26 \ldots\ldots (3).$$

Now since $E>23$, we have for P and l,

$$P=54-E=54-26=28,$$

$$l=\left(\frac{57-E}{7}\right)_r=\left(\frac{57-26}{7}\right)_r=\left(\frac{31}{7}\right)_r=3;$$

consequently, since $p=P+(L-l)$

$$p=28+(4-3)=29;$$

that is to say, Easter happens twenty-nine days after the 21st of March, or on the 19th of April, the same result as was before found from the tables.

The principal church feasts depending on Easter, and the times of their celebration, are as follows:

Septuagesima Sunday	is	9 weeks	before Easter.
Ash Wednesday......	is	46 days	before Easter.
Rogation Sunday....................	is	5 weeks	after Easter.
Ascension day or Holy Thursday	is	40 days	after Easter.
Pentecost or Whitsunday.........	is	7 weeks	after Easter.
Trinity Sunday......................	is	8 weeks	after Easter.

The Gregorian calendar was introduced into Spain, Portugal, and part of Italy, the same day as at Rome. In France it was received in the same year in the month of December, and by the Catholic states of Germany the year following. In the Protestant states of Germany the Julian calendar was adhered to till the year 1700, when it was decreed by the diet of Ratisbon that the new style and the Gregorian correction of the intercalation should be adopted. Instead, however, of employing the golden numbers and epacts for the determination of Easter and the movable feasts, it was resolved that the equinox and the paschal moon should be found by astronomical computation from the Rudolphine tables. But this method, though at first view it may appear more accurate, was soon found to be attended with numerous inconveniences, and was at length, in 1774, abandoned at the instance of Frederic II. king of Prussia. In Denmark and Sweden the reformed calendar was received about the same time as in the Protestant states of Germany. Russia still adheres to the Julian reckoning.

In Great Britain the alteration of the style was for a long time successfully opposed by popular prejudice. The inconvenience, however, of using a different date from that employed by the greater part of Europe, in matters of history and chronology, began to be generally felt; and at length, in 1751, an act of parliament was passed for the adoption of the new style in all public and legal transactions. The difference of the two styles, which then amounted to eleven days, was removed by ordering the day following the 2d of September of the year 1752 to be accounted the 14th of that month; and in order to preserve uniformity in future, the Gregorian rule of intercalation respecting the secular years was adopted. At the same time, the commencement of the legal year was changed from the 25th of April to the 1st of January. In Scotland, the new style was adopted from the beginning of 1600, according to an act of the privy-council in December 1599. This fact is of importance with reference to the date of legal deeds executed in Scotland between that period and 1751, when the change was effected in England. With respect to the movable feasts, Easter is determined by the rule laid down by the council of Nice; but instead of employing the new moons and epacts, the golden numbers are prefixed to the days of the *full* moons. In those years in which the line of epacts is changed in the Gregorian calendar, the golden numbers are removed to different days, and of course a new table is required whenever the solar or lunar equation occurs. The golden numbers have been placed so that Easter may fall on the same day as in the Gregorian calendar. The calendar of the Church of England is therefore from century to century the same in form as the old Roman calendar, excepting that the golden numbers indicate the full moons instead of the new moons.

The principal works on the calendar are the following:—Clavius, *Romani Calendarii a Gregorio XIII. P. M. restituti Explicatio*; Romæ, 1603. Lalande, *Astronomie*, tom. ii. *Traité de la Sphère et du Calendrier*, par M. Revard; Paris, 1816. Delambre, *Traité de l'Astronomie Théorique et Pratique*, tom. iii. *Histoire de l'Astronomie Moderne. Methodus technica brevis, perfacilis ac perpetua, construendi Calendarium Ecclesiasticum, Stylo tam novo quam vetere, pro cunctis Christianis Europæ populis, &c*, auctore Paulo Tittel; Gœttinguæ, 1816. *Formole analitiche pel calcolo della Pasqua, e correzione di quello di Gauss, con critiche osservazioni sù quanto ha scritto del Calendario il Delambre*, di Lodovico Ciccolini; Roma, 1817. (T. G.)

CALENDER, a mechanical engine employed by cloth-lappers, for dressing and finishing cloths and stuffs of various descriptions and fabrics, before exposure to sale, or delivery to purchasers. It is also used by calico-printers, in order to extend and smooth the surface of their cloths, after they have been bleached, and before they are subjected to the operations of the printing table or copper-plate press.

In all cases two, and in many three requisites must be attained, in order to give to cloth that appearance which it is deemed necessary that it should possess, to attract the eye and gratify the fancy of the purchaser and consumer.

The *first* of these requisites consists in as perfect extension and smoothness of surface as can be attained; so that no wrinkle or doubled folding may remain in it, excepting such as shall afterwards be intentionally made, in order to the reducing of it to the proper form and shape.

The *second* requisite acquired by the calendering of cloth, is the compression of the yarn or threads of which the texture is composed, which in some degree divests them of their cylindrical shape, and reduces them to a degree of flatness, which, by bringing them more closely into contact with each other, gives to the fabric a greater appearance of closeness and strength than it would otherwise possess. The operation of the calender also improves the superficial appearance, by flattening down all knots, lumps, and other imperfections, from which no material from which cloth is fabricated can ever be entirely freed during the previous processes of spinning and weaving.

And, *thirdly*, in many fabrics it is desirable, and esteemed a great addition to the effect and beauty of the superficial appearance, that cloth should receive, by means of friction, an additional lustre or polish, which is generally distinguished by the appellation of glazing, and is chiefly required in those stuffs which are employed in the ornamental descriptions of female attire.

Such, in a strictly limited sense, are the sole and exclusive effects resulting from the mechanical operation of the calender; but, as other operations besides smoothing or glazing are necessary for the proper preparation of cloths for the market, these also are carried on by the same persons, and in the same premises. Hence by a natural, although not strictly correct, extension of its acceptation, the term calender, which really means only the chief mechanical engine employed, gives the general name to the whole establishment where all the varied operations of cloth-lapping are carried on; and it is as usual to say that goods are *packed*, as that goods are *dressed*, at a calender. In the illustration, therefore, of those operations which the limits of this article will admit, the first object will be to convey a distinct idea of the principles, construction, and operation of the principal machinery employed; and then to add such general and miscellaneous observations as may serve to elucidate how the business of cloth-lapping is carried on in its present extended form.

For the purpose of smoothing both surfaces of a piece

of cloth, it is necessary that they should be exposed to universal contact and pressure in every point, with some body of sufficient density to acquire the requisite degree of superficial polish. Such equality of surface, however, as will produce this effect, is not very easily attainable in large plane surfaces. Hence the contact of cylinders in this operation has been found to be in all respects infinitely preferable to that of planes, both in the speed and the effect of the operation. The common domestic smoothing iron is the most simple of all calendering utensils; but, even in the application of its small and limited surface, it would be difficult to procure any table or board sufficiently level to bring the whole cloth into equal contact with the iron, without the intervention of a few folds of blanket, or some other thick and soft woollen cloth.

The old and now almost entirely superseded machine termed a *mangle* gives the most simple and rude approximation towards cylindrical calendering, and the substitution of circular for plane surfaces. Its operation is that of a cylinder applied to a plane, upon which it is rolled backward and forward, until some degree of smoothness is produced by this reciprocating motion. It is, therefore, very analogous in principle to the common gardener's roller, with which land is resmoothed after having been dug up for sowing or other agricultural purposes.

The smoothing calender completes the substitution of cylindrical for plane surfaces, all the parts which operate upon the cloth being of that form. This ingenious engine, which was introduced into Britain from Flanders and Holland, during the persecution of the Huguenots, has, since its introduction and adoption here, undergone no very material or important alteration or improvement in point of theoretical principle; nor, until the extension of the cotton manufacture had introduced a general spirit of mechanical improvement, had it received any great amelioration in practical execution. Two very important improvements have, however, since that period been introduced and adopted. The first of these, which originated in Lancashire, is now almost universally employed. The second was invented at Glasgow.

The scope of the former of these improvements consists in the substitution of pasteboard in the place of wood, in constructing three out of the five cylinders of which the engine is composed. These cylinders, when previously composed of wood, were found to be liable to two serious and important objections. Calenders employed in general business are necessarily subjected to frequent alternations and vicissitudes of heat and cold. These are entirely unavoidable, because, in smoothing or dressing cloths of the denser fabrics, the effect, as in the common operation of ironing linens, is found to be greatly heightened by the application of as great a degree of heat as can safely be communicated without danger to the fabrics which are to be smoothed.

The expansion of every thread which composes a given extent of cloth, although individually indistinguishable, even with microscopic aid, produces very considerable general effect, when exerted upon eight or ten thousand of these minute cylindrical substances, all combined together in the space of one single square yard. In this expanded state, the pressure of the calender divests them more easily of their cylindrical form, and flattens them down until they come more closely into contact than before. This effect, which is in exact unison with the general theories of expansion and contraction, will at once produce an apparent increase of closeness and density to the texture, as well as of gloss to the surfaces; although the former is in fact deceptive, as no *real* acquisition of strength to the fabric can thus be obtained. The apparent density of fabric, as well as a higher accession of gloss, is also frequently obtained by impregnating and stiffening the cloth, after it has been bleached, with a mucilage of starch; and this is too frequently carried to a very unfair height, for the purposes of deception, which is not very easily detected, until the cloth be again exposed to moisture, when the delusive appearance instantly vanishes. Hence, in all dense fabrics, the calender is generally used in a heated state; whilst in flimsy fabrics, in which transparency of appearance is more the requisite than strength, the operation is conducted with the calender perfectly cold.

The effect of these frequent and sudden transitions upon wooden cylinders was necessarily productive both of *fissure* and *warping* or *twisting*; and no care in drying or seasoning the wood before turning could entirely remove these defects. The substitution of pasteboard, however, afforded a radical cure for both, as well as a collateral advantage arising from its being susceptible of a much higher degree of superficial polish, which is always transferred to the cloth.

The paper or pasteboard cylinder, besides total exemption from all defects incidental to ligneous substances, from the immense density of which it is susceptible by compression, presents a superficies capable of receiving and retaining an almost unparalleled smoothness and polish.

In order to construct cylinders of this description, an axis of malleable iron, and two circular plates of cast iron, are, in the first place, provided. In these plates, which must be at least from one to two inches thick, there are six equidistant perforations near to the circumference, each capable of admitting a rod of malleable iron at least three fourths of an inch in diameter. The entire space between the two iron plates is then to be filled with circular pieces of the strongest pasteboard, exceeding by about one inch in diameter the iron plates, and having each a correspondent perforation, through which the six iron rods may pass parallel to the axis. A cylinder is thus formed, the substance of which is of pasteboard locked together by plates of iron at the extremities, and susceptible, by means of screws on the extremities of the six connecting rods, of immense compression. After undergoing this preparation, the cylinder is exposed to strong heat in a confined apartment; and, as the pasteboard daily contracts, the screws are every day tightened for the space of six days. The density of the cylinder is thus increased, whilst it is contracted in length upon the axis, for which contraction adequate allowance must be made in its original measure, and the operation is continued until it has gradually acquired the requisite compression. It is then re-exposed to the ordinary temperature of the atmosphere, and by its re-expansion presents a body almost inconceivably compact, its specific gravity in this state being greater than even that of silver. The only operation now required is that of turning its superficies until correctly cylindrical; and this is a work of immense labour and patience.

The rotatory motion in turning does not exceed forty or fifty revolutions per minute; and the turner requires two or three assistants constantly employed in sharpening his tools. When properly finished and smoothed, a pasteboard cylinder, however, amply compensates, by its strength, its gloss, and its durability, for the great labour and expense which its construction has created.

A second practical improvement in calenders of the common description consists in the substitution of cast iron for wood in the construction of the connecting frames. This improvement is now common to almost every description of machinery; and when applied to the calender, it is of more than usual advantage, because, independently of the accession of strength and diminution of space occupied, the total exemption of iron from warping is of

Calender. peculiar advantage in an engine so rapidly exposed to alteration of temperature as the calender must be. The entire exemption of iron framing from combustion forms also another advantage of some importance in an engine frequently heated by the application of red-hot cylinders of iron. With this cursory outline of general improvement, the next object of the present article is to afford a description of the new glazing calender.

Glazing calender. Previously to the introduction of this improvement, the operation of glazing, although performed sufficiently well, was somewhat tedious, being effected almost exclusively by the mere application of manual labour. It was performed upon a table, the cover of which was oblique to the horizon, forming with it an angle of 15° or 20°. The cloth being stretched on this, and a quantity of wax being thinly spread on its surface, the glazing was effected by the reciprocation of a smoothed flint, vibrating at the end of a rod, somewhat similar to the oscillations of a pendulum. The centre of oscillation was also movable on a spring, in order to reduce the arc of vibration to a plane, and keep the flint in uniform contact with the cloth. But a man's power was competent to glaze only a few inches in breadth at once, and it was only by successive shiftings that the whole breadth was successively brought under the friction of the flint. The glazing calender produces the same effect, with increased uniformity, simply by changing the relative velocities of the cylinders to each other, and generating friction, as well as pressure, at the points of contact. The process of flint glazing is still practised in Manchester, but on a large scale, the operation being carried on by means of steam power.

The following is a description of the new glazing calender. Fig. 1, Plate CLIV. is an elevation of a five-rollered calender for finishing cloth. AA are two paper rollers, of twenty inches diameter each. BB are two cast-iron cylinders, externally turned until perfectly smooth; their diameter is eight inches, allowing the substance of iron to be two inches, and leaving a perforation of four inches diameter. C is a paper roller of fourteen inches diameter; DD is the framing of cast iron for containing the bushes in which the journals of the rollers revolve; EE are two levers by which the rollers are firmly pressed together while the cloth is passing through.

Fig. 2 is an end view of the same calender, with the wheels for glazing cloth. The wheel on the upper cylinder is ten inches diameter, the wheel on the under cylinder is thirteen inches diameter, both connected by the wheel F, which communicates the speed of the upper cylinder, so that the wheel on the under cylinder being nearly one third of an inch more in diameter, the difference of their motions retards the centre paper roller, by which means the upper cylinder passes over the cloth one third faster than the cloth passes through the calender, and polishes it in consequence.

Fig. 3 is a perspective view of a hydrostatic press. A, the piston, eight inches diameter, working in the cylinder B, and kept water-tight by passing through a collar of leather; D, a cast-iron plate raised by the piston A, between which and the entablature EE the goods to be pressed are laid; CCCC, four malleable iron columns, $2\frac{3}{4}$th inches diameter, having screwed ends, with nuts, by which the entablature and the base FF are firmly connected together. G, a cistern for holding water to supply the two force-pumps HI, the largest of which has a piston $1\frac{1}{2}$ inch diameter, and the other one of half an inch diameter, which is used to give the highest pressure; KK, weights to balance the pump-handles which fit into the sockets at *ll*. The pistons of the force-pumps are made water-tight by collars of leather, kept in their place by the screwed pieces *m* and *n*. *e e e*, a pipe communicating with the pumps and the large cylinder B; there is a stop-cock at *f*, which shuts this communication when required. Calender.

Fig. 4 is an enlarged view of the largest piston, to show the method of keeping the rod parallel.

For dressing muslins, gauzes, lawns, and other goods of the light and transparent fabrics, a smaller species of calender is employed. It consists of only three cylinders of equal diameters (generally about six inches), and is easily moved by a common winch or handle. The middle cylinder is iron, and the others are wood or pasteboard. They are of equal diameters, and are moved with equal velocities by small wheels. This machine is always used in a cold state. Small calender for light fabrics.

The folding of cloth is so entirely regulated by fashion, that no precise rules can be laid down for its regulation. In general, as all the different manufactures of cloth have been imported from other countries, the original foldings have been copied to complete the resemblance. In the infant state of imitation there was probably some policy in this, but the continuance may be ascribed almost exclusively to the power of habit. Preservation and portability are the main requisites to be attained by folding; and these are attained by subjecting the cloth, when folded, to a very powerful compression.

Water-presses upon the forcing principle of Mr Bramah, or acted upon by the pressure of a column of water, are now in general use in Glasgow and Manchester. Besides the immense power thereby procured, the labour of pressing is much lessened. No improvements that have taken place in calendering can exceed the power and facility of the water-press; one of these presses is generally wrought by two men, who can with great ease work the press so as to produce a pressure of four hundred tons; and thereby the appearance and finish of the goods, in consequence of such an immense weight acting on them, are materially improved. Not only this, but the Bramah press is also used for the purpose of packing, which has increased the method of packing in bales considerably. The bale is commonly packed, roped, &c. while in a compressed state; the dimensions are therefore greatly diminished from what they would otherwise be by any other method; for instance, the same quantity of goods packed in a bale would be one third less in size than if they were packed in a box. Bramah's water-presses.

To the mechanical art of calendering it is found expedient, in the extended states of commerce, to add many of the operations of packing, sheeting, and preparing goods for shipment; and these generally form a branch of the establishment. In order to suit the great extent and variety of manufacture practised in Britain, and to adapt these to the prevalent tastes and views of the extensive range of consumers to be supplied, a multiplicity of foldings or lappings has been necessarily adopted, few of which probably possess much claim to entire originality. The high, and perhaps pre-eminent, station which the productions of the British looms have gradually attained, seem to be rather the effect of assiduous and enterprising industry, than of great originality of invention, or precedence in mechanical improvement. Certainly she can, at the utmost, boast of only one *raw material*, from which cloth is manufactured, as peculiarly indigenous. Operations connected with calendering.

At an early period, no doubt, the British wool had attracted the peculiar attention of economists and statesmen as of paramount value; and the prohibition of its exportation became an object of legislative enactment. That manufacture, therefore, has long been the staple of England, as the linen trade, at a later period, has become that of Ireland.

The attempts to introduce both of these branches of industry into Scotland, although, during the latter part of

the last century, they engrossed much of the attention both of public bodies and of patriotic individuals, cannot be regarded as having proved eminently successful; and the progress actually made has been almost entirely superseded and extinguished by the more recent introduction of the cotton manufacture.

The latter branch of industry, since the splendid invention of spinning by the aid of machinery, has indeed made most rapid advances in every part of the united kingdom, and has attained to a height which has, perhaps, absorbed a greater portion of national industry than consumers can easily be found to employ. The extension of external commerce has constantly supplied the raw material at easy and generally moderate rates; and even the India Company have long ceased to oppose to it any very formidable competition in the market.

The silk manufactures of Britain formerly were not carried on to a very great extent; they have now, however, increased considerably. Whatever may have, directly or indirectly, tended to regulate the finishing, folding, and preparing of British goods for the various markets of consumption, will chiefly refer to the three former branches of manufacture.

Extensively as the woollen trade is carried on, it is in a great measure absorbed either by internal or colonial consumption, and does not, therefore, enter so generally into actual competition with the cloths of other nations, as to render it either peculiarly desirable that its marketable aspect should be either servilely copied from those of other countries, or very peculiarly distinguished from them. The chief object appears to have generally been, to prevent the intrusion of foreign cloths and stuffs into our own markets; and hence adopting their usual folds into such rolls as most effectually preserve the dressed surface from acute cresses, is found to be most expedient and convenient, the goods being distinguished by letters denoting them to be "British manufacture" on the ends of the pieces.

In the Irish manufactures of cambrics and linens, the case is almost entirely reversed. From the superiority of climate, the French flax is admitted to be of finer appearance; and although the importation of manufactured cambrics be strictly prohibited, the restraint during periods of peace has always been considerably evaded, in consequence of the demand experienced, and the reputation in which they are held. Indeed it was found generally most expedient, by many retailers, to sell Irish cambrics under the title of French, and hence the fold was correctly imitated. The pieces, after being folded into lengths of about twelve inches, and twice laterally doubled, until the whole breadth of thirty-four inches was reduced to about eight and a half inches, were subjected to a powerful compression in the press until fully flattened. They were then packed in purple coloured wrappers or papers, and a small engraved card or ticket was attached to each piece, specifying the length, generally about eight or eight and a half yards. The cards were attached by a silken string, so as to be easily cut away with a penknife or pair of scissors, in order to avoid seizure; and French or Irish goods were sold indiscriminately as "foreign cambrics." Custom has even carried this practice farther; and cotton cambrics, which are avowedly *British manufacture*, and subjected to no risk whatever, because easily distinguishable from any cambric manufactured from flax, are put up into the same folds, papered, and ticketed, in exactly the same manner.

In linens, hollands, and sheetings, whether of foreign or Irish manufacture, the same fold is also employed; and in cotton shirtings and sheetings it is closely imitated. The form is that of a cylindric roll, somewhat flattened by subsequent compression; and, in general, all dense fabrics, whether of linen or of cotton, are rolled up and compressed in a similar manner, the object of which is evidently safety and diminution of space in land carriage or exportation.

In others of the extensive varieties of cotton cloths of British manufacture, some are avowed imitations of the manufactures of Hindustan, whilst others profess no such imitation. Very few among the manufactures of Lancashire are either distinguished by Indian names, or copied from Indian cloths, although some of great extent are directly so. Calicoes, cossacs, and jaconets, for printing, as well as Ballusore, Bandana, and Pullicate handkerchiefs, are amongst the leading articles of the latter description; whilst among the former may be classed the very extensive manufactures of corduroys, thicksetts, velveretts, velveteens, &c. although their origin is also probably Asiatic, but because well known and manufactured by the Genoese, French, and other European nations, even before the discoveries of De Gama and other mariners had first laid open the maritime intercourse with India by the Cape of Good Hope.

When, at a period infinitely more recent, the splendid invention of spinning cotton by the agency of machinery to any degree of fineness afforded new scope to the British weaver, the imitation of the lighter Indian fabrics fell chiefly into the hands of the Scottish weavers, for executing which they had been in a considerable degree previously prepared, by their habits of weaving lawns in imitation of the French, as well as their lighter fabrics of silk and thread gauzes. To their share, in consequence, fell the bouks, mulls, and japuns, almost exclusively, as well as the lighter jaconets, designed for ornament from the needle and tambour frame. And whilst they have made no successful attempt to compete with their Lancashire brethren in the dense fabrics of corduroys, quiltings, and other ponderous articles, they have shared with them the manufacture of the middling textures of cambrics, Pullicates, and ginghams.

Indeed, whatever prepossession may, at an early period, have existed in favour of the real Indian fabrics, it has now so entirely subsided as to possess no influence whatever in swaying general opinion. The British workmanship has proved itself long ago so decisively superior to the Indian, both in spinning and weaving, as to eradicate every doubt in the minds of all who are really competent to decide the question of comparative superiority. Still, however, candour will compel us to allow that the Indian possesses advantages in the rich qualities of his cotton, and the brilliancy of some of his dyes, which, in some degree, compensate for the immense superiority of the British skill and machinery, and which, to those who examine superficially, may appear to entitle him to the preference.

Nothing, therefore, exists in the cotton manufacture which could, in general cases, prompt to a servile imitation of external appearance for the purposes of deception; and the Indian mode of lapping their cloth is too rude and laborious to admit of its being copied as a matter of convenience. Their method consists merely in doubling a piece of twenty yards, to reduce its length to ten yards, which is again doubled, in order to reduce it to five; and thus they continue to redouble, until the piece be reduced to a moderate length, capable of being contained in a chest or bale. Thus often redoubled, an Indian piece cannot be examined throughout unless the whole piece be again unfolded; and this, in large transactions, would be utterly impracticable.

British muslins are folded generally to a yard in length, with a small allowance for extra measure; and as the folding is alternately from right to left, every part can be

instantly examined upon a table or counter, every fold opening as easily as the leaves of a book in its uncut state. The piece, when folded, is reduced by doubling it longitudinally to about nineteen inches, and it is then folded across to the breadth of about thirteen inches. An ordinary sized trunk, 39 × 19 inches, thus contains three layers of pieces, in which package goods for exportation to the colonies are generally packed, the trunk there forming an article of merchandise as much in general demand as the muslins which it contains.

Even the Indian ornaments of gilt silver threads which were at first woven into one end of each piece, although they did not exceed the value of twopence each, have been either greatly curtailed, or totally given up upon principles of economy. Even the cost of this trivial ornament has been computed to have amounted annually in Glasgow and Paisley to about L.30,000.

Pullicate and other handkerchiefs are most commonly folded up in dozens. For the African and some other foreign trades, pieces containing only eight handkerchiefs are preferred. These are still imitations of Indian precedents, confined to markets where competition continues to exist, not only with the British Company, but with Americans and others trading to India. A species of pale orange-coloured India handkerchiefs, distinguished by the name of *Madras*, being in extensive reputation in the Caraccas and other Spanish settlements in South America at the period of the capture of Trinidad in 1795, patterns were procured by some British traders, who ordered very large quantities to be manufactured in Scotland of the same quality and appearance. With such effect were these imitated in texture, in dye, in finishing, and even in the packages, that some hundreds of pieces sent to London for exportation were actually seized at the customhouse as India goods, either illegally imported, or stolen from some of the Company's ships in the river. A scrutiny, however, clearly ascertained that these goods were not Indian, but British, and that no trespass against either the privileges or the property of the Company had been even attempted. The goods were of course released, and permitted to proceed to their destination, where, after examination and trial, it was found totally unnecessary longer to conceal their real origin; and a very extensive trade, through direct channels, has been since carried on for similar goods.

General observations.

From the above general and cursory sketch, it will be obvious that the management of an extensive calendering establishment will require, on the part of its conductor, not only a competent knowledge and experience of the mechanical operations and duties of his particular profession, but that a more extensive mercantile acquaintance with the demands, habits, and tastes of particular markets, will conduce equally to his own interests and those of his employers. From the variations of markets, and fluctuations of mercantile transactions, there can be no precise or definite limit to the extent of such knowledge. It is only by constant attention and sedulous inquiry that he can preserve accuracy in what is liable to almost daily change. His immediate employers will no doubt be often both able and desirous to supply him with this. But as even they must sometimes be liable to error or deception, he ought to omit no opportunity of extending his inquiries, and arriving, as nearly as he can, at the most comprehensive and unambiguous information. (J. D—N.)

CALENDERS, a sort of Mohammedan friars, so called from the santon Calenderi, their founder. They are called in Persia and Arabia *Abdals*, or *Abdallat*, that is, persons consecrated to the honour and service of God. See ABDALS.

CALENTURE, a feverish disorder incident to sailors in tropical climates, of which the principal symptom is their imagining the sea to be green fields.

CALENZIO, or CALENTIUS, ELISEO, a Latin poet and prose writer of the fifteenth century, born at Puglia in the kingdom of Naples. He was preceptor to prince Federigo, son of Fernando I. king of Naples, and was connected by ties of friendship with Sannazarius, Altilio, and other eminent scholars of that period. He seems to have anticipated many of the later improvements in penal legislation, and was the earliest writer against capital punishment except for murder. He died in 1503. There have been three editions of his works, two at Rome (one in 1503, folio), and the third at Basle, 1554.

CALEPINO, AMBROGIO, an Augustine monk, born at Bergamo in 1435, was descended of an old family of Calepio, whence he took his name. He devoted his whole life to the composition of a polyglott dictionary, first printed at Reggio in 1502. This gigantic work was afterwards augmented by Passerat and others. The most complete edition, published at Basle in 1590, comprises no fewer than eleven languages. Calepino died blind in 1511.

CALF, the young of the ox kind. See MAMMALIA.

CALF, Golden, an idol set up and worshipped by the Israelites at the foot of Mount Sinai, in their passage through the wilderness to the land of Canaan. Our version makes Aaron fashion this calf with a graving tool after he had cast it in a mould. The Geneva translation makes him engrave it first, and cast it afterwards. Others, with more probability, render the whole verse thus:—"And Aaron received them (the golden ear-rings), and tied them up in a bag, and got them cast into a molten calf;" which version is authorized by the different senses of the word *tzur*, which signifies to tie up or bind, as well as to shape or form; and of the word *cherret*, which is used both for a graving tool and a bag. Some of the ancient fathers have been of opinion that this idol had only the face of a calf, with a human body from the neck downwards, in imitation of the Egyptian Isis; while others have thought it was only the head of an ox without a body. But the most general opinion is, that it was an entire calf, in imitation of the Apis worshipped by the Egyptians; among whom, no doubt, the Israelites had acquired their propensity to idolatry. This calf Moses is said to have *burnt with fire*, reduced to powder, and strewed upon the water which the people were to drink. How this could be accomplished has been a question. M. Stahl conjectures that Moses dissolved it by means of liver of sulphur. The rabbins tell us that the people were made to drink of this water, in order to distinguish the idolaters from the rest; for that as soon as they had drunk of it the beards of the former turned red. The Cabbalists add, that the calf weighed 125 quintals; which they gather from the Hebrew word *massekah*, whose numerical letters make 125.

CALI, a town of New Granada, South America, near the river Cauca, in a fertile and populous plain, abounding in mines, vegetable productions, and cattle. It is 60 miles north of Popayan, and has a population of about 4000. Long. 76. 33. W., Lat. 3. 24. N.

CALIAN, a town of Hindustan, in the British district of Tannah, presidency of Bombay. It was formerly of larger size and of greater importance than it is at present. It was exposed to many sieges during the wars which were carried on between the Mohammedans and the Mahrattas, and is now surrounded by the ruins of numerous forts. It is 32 miles N.E. from Bombay; and being situate on the line of the Great Indian Peninsula railway, will in all probability shortly regain its ancient prosperity. Long. 73. 12. E., Lat. 19. 14. N.

CALIBER, or CALIBRE, the diameter of any body, as the calibre of a column, of a bullet, &c. It also denotes the size of the bore of a gun.

CALIBER *Compasses*, or *Callipers*, compasses made with arched legs, to measure the diameter of round or swelling bodies. See COMPASSES.

CALIBER *Rule*, or *Gunner's* CALLIPERS, is an instrument in which a right line is so divided that the first part being equal to the diameter of an iron or leaden ball of one pound weight, the other parts are to the first as the diameters of balls of two, three, four, or more pounds are to the diameter of a ball of one pound. It is used by engineers to determine, from the weight of the ball given, its diameter or caliber, or *vice versa*.

The gunner's callipers consist of two thin plates of brass joined by a rivet, so as to move quite round each other. Its length from the centre of the joint is between six inches and a foot, and its breadth from one to two inches; that of the most convenient size is about nine inches long. Many scales, tables, and proportions, &c. may be introduced on this instrument; but none is essential to it except those for taking the caliber of shot and cannon, and for measuring the magnitude of salient and re-entering angles.

CALICO, so called from Calicut in India, a sort of cotton cloth. In England, white or unprinted cotton cloth is called calico. In the United States, calico is printed cotton cloth of not more than two colours.

CALICO-PRINTING. See DYEING.

CALICUT, a seaport-town of Hindustan, in the British district of Malabar, presidency of Madras. It was formerly an extensive and magnificent city, but now exhibits few vestiges of its original splendour. It was at this city that Vasco de Gama arrived in May 1498, ten months and two days after he had departed from Lisbon, being the first place in India visited by any European navigator. It then contained several stately buildings, and among them a Brahminical temple, not inferior to the largest monastery in Portugal. The town stands on the sea-shore in a low and unsheltered situation, and its streets are narrow and dirty. It is however populous, and though there is neither river nor haven, and ships are compelled to anchor in the open sea, it is nevertheless the seat of considerable trade. The port is frequented by vessels from the Red Sea and the Persian Gulf, which return with freights of rice, cocoa-nuts, pepper, ginger, and sandal-wood. In 1510, the Portuguese, commanded by Albuquerque, attacked Calicut with 3000 troops, burned the town and plundered the palace, but were finally repulsed and fled to their ships after sustaining heavy loss. Shortly after they concluded a peace with the zamorin, who permitted them to erect a fortified factory here. This town was taken in 1773 by Hyder Ali, who expelled all the merchants and factors, destroyed the cocoa-nut trees, sandal-wood, and pepper vines, that the country, reduced to ruin, might present no temptation to the cupidity of Europeans. In 1782, the troops of Hyder were driven out from Calicut by the British; but in 1782 it was taken and destroyed by his son Tippoo, who carried off the inhabitants to Beypore, and treated them with detestable cruelty. In the latter part of 1790 the country was occupied by the British; and under the treaty concluded in 1792, whereby Tippoo was deprived of half his dominions, Calicut fell to the British, and was formally incorporated with their dominions. After this event the inhabitants returned and rebuilt the town, which in the year 1800 consisted of 5000 houses. Distant from Bombay S.E. 566 miles; Mangalore, S.E. 130; Madras, S.W. 335. N. Lat. 11. 15., E. Long. 75. 50.

CÂLIDÂSA, an Indian poet, whose drama, *Sacuntalâ*, was first made known to Europe by Sir William Jones' translation, published at Calcutta in 1789. The discovery of a Sanscrit copy of this poet's works in the Royal Library at Paris, published in 1832, showed that the drama translated by Jones was from the interpolated and corrupted text, which has long been circulated in Bengal. Several other poems by Câlidâsa have since been published; all of which show an elevation of sentiment, and purity of feeling, rarely seen in Asiatic poetry; while his fervid descriptions and vivid imagery have procured for him the highest admiration in the East.

CALIFORNIA, an extensive region of North America, extending along its western coast from 22. 48. to 42. N. Lat. and lying between 106. and 124. W. Long. It is bounded on the north and east by the United States' territories and the Gulf of California, and on the south and west by the north Pacific Ocean. It is divided into Old or Lower, and New or Upper California. Previous to the treaty of 1848, by which Upper California was ceded to the United States, they both formed part of the territory of the Mexican Republic. Lower California still belongs to that republic.

LOWER CALIFORNIA is a long narrow peninsula, extending from 22. 48. to 32. 30. N. Lat., and separated from the mainland by the Gulf of California. On the north it is bounded by Upper California, east by the Gulf of California, and on the south and west by the ocean. It is about 700 miles in length, and from 30 to 100 miles in breadth; with an estimated area of about 60,000 square miles, and a population of probably not more than 20,000.

This peninsula is traversed from north to south by a chain of rocky mountains varying in height from 1000 to 5000 feet above the level of the sea. These are entirely destitute of verdure, with the exception of here and there a cluster of briars, small shrubs, or dwarf trees, and some few spots in the ridges where the soil is protected from being washed away by the tornadoes, which every few years sweep over the country with such violence, and bearing with them such floods of rain, that whatever of soil has been in any manner previously formed is swept into the sea. The spots so protected are, if well watered, very fertile; but they are rare and of small extent. The rest of the country is interspersed with extensive tracts of sandy soil nearly as barren and unproductive as its rocky mountains, but near the coast there are some few places which are well adapted for cultivation. Altogether, however, this country is one of the most barren and unattractive to be found in the temperate or hotter regions of the earth. According to Farnham, the products of the soil will never maintain 500,000 people in a state of comfort ordinarily found in the civilized condition.

The scarcity of water is one of the great disadvantages under which this region labours. Like other countries of volcanic origin, the porousness of the rocks allows the water to pass underground to the sea, so that few streams or springs are found in Lower California. From Cape San Lucas, its most southern point, to the mouth of the Colorado, 600 miles, there are only two streams entering the gulf. One of these is the San Josef del Cabo, which passes through the plantations of the mission of the same name, and discharges itself into the bay of San Barnabas. The other is the Mulege, which waters the mission of Santa Rosalia, and enters the gulf in Lat. 27° N. These are not navigable. The streams on the ocean coast are also few and small, none of them being navigable. In the interior are several large springs, which send out copious currents along the rocky beds of their upper courses, but which, on reaching the loose sands and porous rocks of the lower country sink and enter the sea through subterraneous channels. There are some tolerable harbours, but these, from the state of the country, are useless except as places of refuge. The country is said to be rich in minerals, but no mines are wrought except the gold and silver mines of San Antonio, in about 24° N. Lat., and even these afford only a trifling supply. Lead is said to be found towards the southern extremity of the peninsula.

The climate is very hot and dry. The rains fall in the winter months, and are very severe, but of short duration. Summer rains seldom occur north of Loretto, in Lat. 26° N. For the space of 20 or 30 leagues from Cape San Lucas,

the air is rendered mild and agreeable by the sea-breezes, and the ground in many parts is very fruitful, being watered by numerous little streams from the high lands. Thence to Loretto the heat is excessive, the soil dry and barren, and the surface of the country extremely craggy and forbidding. From Loretto northward the air is more temperate; the water in the mountains sometimes freezes, and the soil though not so rugged and full of rocks, is barren and desolate as that around Loretto. In summer the mean temperature of the country ranges from 60° to 74° Fahr. On the shores of the Pacific the temperature is rendered agreeable by the sea-breezes, and the humidity which they carry with them. On this coast the temperature during summer ranges from 58° to 71° Fahr., and during the rainy season it falls as low as 50°. On the Gulf coast there is a still greater variation; while at the Cape the mercury stands between 60° and 70° degrees, near the head of the Gulf it is down to the freezing point. Violent hurricanes are frequent, but earthquakes seldom occur.

Besides maize, wheat, peas, &c., the few fertile spots of this region produce a variety of fruits, such as grapes, dates, figs, quinces, peaches, pears, and olives. The dates, figs, &c., are preserved; some wine is made; and a kind of spirit is distilled from the mescal. The cattle are numerous, and feed in part on the leaves of the musquito, a species of acacia. Wolves, foxes, deer, goats, several lizards and scorpions, are among the wild animals. Pearls, tortoiseshell, a few hides, dried fruits, dried beef, cheese, soap, &c., constitute its exports, and are mostly sent to San Blas, Mazatlan, and Guayamas, in small coasting vessels. The imports are provisions, clothing, agricultural and domestic utensils, supplies for the ceremonies of the church, and a small amount of the ordinary luxuries of life.

Though the land is thus barren and unproductive, the sea is stored with an incredible abundance and variety of fish. Among these may be mentioned the halibut, salmon, turbot, skate, pilchard, mackerel, sole, lobster, cod, anchovy, and pearl-oyster. The immense beds of pearl-oysters in the gulf have long been a source of attraction to adventurers, and employ several hundreds of Indian divers.

The peninsula of Lower California was discovered by Hernandez de Grijalva in 1534, but no settlement was made by the Spaniards till about the end of the next century, when some Jesuits established themselves there with the view of converting the natives. Loretto, the capital, and the other towns, were founded by the Jesuits, who instructed the natives in agriculture, and persuaded many of them to adopt fixed habitations.

California, *Upper*, as ceded to the United States by the treaty of 1848, comprises the region between 32. 30. and 42. N. Lat. and 106. and 124. W. Long.; having an area of 448,691 square miles, or 287,162,240 acres. To give some idea of its extent, we may mention that it contains 1202 square miles more than the States of Maine, Vermont, New Hampshire, Massachusetts, Rhode Island, Connecticut, New York, Pennsylvania, Ohio, Indiana, Illinois, Michigan, Iowa, and Wisconsin combined. This territory is bounded on the north by Oregon, the 42d parallel of N. Lat. being the boundary line between the two territories; on the east by the Rocky Mountains, and the Sierra de los Mimbres, a continuation of the same range; on the south by Sonora and Lower California; and on the west by the ocean. It is 700 miles in length, and 800 miles in breadth.

This extensive territory is naturally divided into two unequal portions lying on either side of the Sierra Nevada range of mountains. The eastern division comprises two portions, the southern being that part of the country drained by the Colorado and its numerous affluents. The other, or N.W. portion of inland California, is known as the "Great Basin," and lies between the Rocky Mountains and the Sierra Nevada, at an elevation of between 4000 and 5000 feet above the sea. It is about 500 miles in diameter, either from north to south, or from east to west; and is surrounded on all sides by mountains, its lakes and rivers having no outlet to the ocean. Its steep interior hills and mountains are covered with forests, and rise abruptly from a base of ten or twenty miles to a height of from 7000 to 10,000 feet. It contains many large bodies of water, among which are the Utah and Great Salt lakes. The plains are arid and sterile, and the greater part of the country is desert; but many parts of it are capable of cultivation. In one of these the Mormons have lately established themselves.

Upper California has, by act of congress, been subdivided to form the State of California, the Territory of Utah, and part of the Territory of New Mexico,—all of which will be found described under their proper heads.

The history of California, previous to its annexation to the United States, presents little of interest to the general reader. It was discovered by Cobrillo, a Spanish navigator, in 1542, but was not colonized by the Spaniards until the latter half of the eighteenth century. The northern part was visited in 1578 by Sir Francis Drake, who gave it the name of New Albion. The first colonies were planted by the Roman clergy, under whose direction missions were established in various parts with the view of converting the Indians to the Catholic faith, and by blending agriculture and trade under the tutelage of the church, to render the Indians valuable subjects of the Spanish crown. The revolution which separated Mexico from Spain, annexed California to that republic; and on the adoption of the federal constitution in 1824 the Californias were erected into territories with power to send a member to the general congress, who, however, was not allowed to vote in its decisions. This was followed by the secularization of the missions. In 1833 the salaries of the monks were suspended, the Indians were relieved from servitude, the funds of the church confiscated, and the division of property among natives and settlers decreed. These blows fell heavily upon the monastic farmers and herdsmen, the missions were speedily deserted, and their edifices and establishments fell into decay. Agriculture had always been most carelessly conducted, and their implements were little improved from those used by the earliest settlers; and notwithstanding the fertility of the country, the productions were only equal to the wants of the inhabitants. In 1831, shortly before the close of the missions, the whole cereal productions of Upper California did not exceed 63,000 bushels of wheat, 28,000 bushels of corn, 4200 bushels of *frijoles* or brown beans, 2800 bushels of *garbanzos* or peas, and 18,500 bushels of barley. The number of missions at that time was 21; the Indian population in these was 18,683; the number of other classes, that is, of the garrison and free settlers, was 4342; making a total of 23,025. A pastoral life seems to have been more accordant to the tastes of the Californians; and accordingly we find that in 1831 there were 216,727 black cattle, 32,100 horses, 2844 mules, 177 asses, 153,455 sheep, 1873 goats, and 839 swine. In addition to these, there were vast numbers of cattle roaming at large, which were not marked or branded according to the Californian laws as belonging to any of the jurisdictions or missions. Yet from all this multitude but little profit was gained, except from hides and tallow, which then formed their only articles of trade; the dairy was altogether neglected, and butter and cheese almost unknown. The natives and settlers soon became dissatisfied with the national government that succeeded the milder sway of the clergy, and more than once the people declared themselves independent, but as often rejoined the confederation. Its distance from the metropolis tended to render its subjection to Mexico of a very nominal character. In 1846 California was occupied by the United States forces; and by the

treaty of Guadalupe Hidalgo on 2d February 1848, the whole country was ceded to that government. In the latter part of the same month, a mechanic named Marshall, employed in building a saw-mill for Captain Sutter, on the south branch of a river known as the American Fork, while cutting a mill-lead, discovered scales of gold in the soil. Pieces of considerable size were taken out, and in a few days gold to the amount of $150 was gathered. The news spread rapidly through the country, and examinations were prosecuted at other points along the stream, and almost everywhere with success. The towns were forthwith deserted by their male population, and a complete cessation of the whole industrial pursuits of the country was the consequence. Commerce, agriculture, mechanical pursuits, professions—all were abandoned for the purpose of gathering the glittering treasure which lay buried in the ravines, gorges, and rivers of the Sierra Nevada. In the mean time, news of the discovered *El Dorado* crossed the continent; and although its marvels were regarded by many as fabulous, there were others who either abandoned their homes for the wilderness, or sent hither valuable cargoes, from the sale of which they drew enormous profits. Under the temptations of trade and discovery, an immense emigration, chiefly of males, poured into California, not only from the United States, but also from Mexico, Chili, Peru, China, the Sandwich Islands, and other parts. Within a year after this wonderful discovery, the Californians felt that they were no longer outlying colonists of the American Union requiring pecuniary support and military protection against savages. Immense fleets arriving from all parts of the world poured large revenues into the national coffers. Intelligent and industrious men thronged the towns that sprang up as if by enchantment at every advantageous point. Property in land and moveables became suddenly valuable beyond the hopes or dreams of the early settlers. In 1849, in consequence of the disorganized condition of society, and the insecurity which generally prevailed, the people by their delegates met in convention at Monterey, on 1st of September, and drew up a constitution, which met with general approval. The main feature of this document is its exclusion of slavery from the state—otherwise it does not differ much from the generality of those of the older states. After a warm discussion in congress at Washington, California was admitted as a state of the Union, on the 9th of September 1850.

California, *State of*, is bounded on the north by Oregon, east by Utah and New Mexico, south by Old California, and on the west by the ocean. The boundary-line, as sanctioned by the act of congress, extends from the ocean along the 42° N. Lat. to its intersection by the 120° W. Long., then southward along the latter to Lat. 39°, thence S.E. to the point where the Rio Colorado intersects the parallel of 35°, thence down the middle of the channel of that river to the boundary-line between the United States and Mexico, along which it continues to the ocean. Its area, exclusive of the islands adjacent to the coast, is 155,550 square miles, or 99,552,000 acres.

It is traversed from north to south by two great ranges of mountains, called respectively the Sierra Nevada and the Coast Range; the former separating this region from the Great Basin, and from 150 to 200 miles distant from the coast; the latter running almost parallel to and at a short distance from the coast. Between these is the great valley of the Sacramento and the San Joaquin rivers, the former traversing the northern and the latter the southern part of the valley; they meet near the centre and pour their united waters into the bay of San Francisco. This valley is about 500 miles in length and 50 in breadth, and presents the appearance of having been at one period the bed of a lake. These two rivers have numerous affluents, many of them of considerable size. Lateral ranges of mountains parallel to the Sierra Nevada and the coast, and varying in height from 2000 to 4000 feet above the sea, diversify the surface of the country. These form greater masses, and become more elevated in the north, where some peaks, as the Shaste, enter the region of perpetual snow. The plains and valleys have only a general elevation of a few hundred feet above the sea. The coast is generally precipitous and rugged, having few good harbours, with the exception of those of San Diego, Monterey, and San Francisco. The bay of San Francisco is indeed one of the finest in the world. It is separated from the sea by low mountain ranges, with an entrance only about a mile wide at its narrowest part, and five miles long from the sea to the bay. Passing through this narrow entrance the bay opens to the right and left, extending in each direction about 35 miles, having a total length of 70, and a coast of 275 miles. It contains numerous islands, some mere rocks, others covered with grass, and rising to the height of from 300 to 800 feet. The surrounding country is picturesque and fertile. A few miles from the shore, and directly fronting its entrance, mountains crowned by forests of lofty cypress rise to the height of 2000 feet, and form a conspicuous landmark for vessels entering the bay. A delta of 25 miles in length, divided into islands by deep channels, connects the bay with the Sacramento and the San Joaquin, both of which are navigable for a considerable distance.

The climate varies considerably in different parts of the country. It is divided into two distinct seasons of wet and dry; the former, at San Francisco, extending from the middle of November to the middle of May. In the southern parts of the country the dry season commences earlier and continues longer than in the northern. The rains, though by no means continuous, are frequent and heavy. During the dry season the prevalence of cold winds and fogs from the sea render the district along the coast very unpleasant to strangers. But in the interior, particularly in the valleys of Sacramento and San Joaquin, the climate is delightful,—the heat during the day not being so intense as along the coast, while the nights are cool and pleasant. On the Sierra Nevada, where the influence of the sea-breeze ceases to be felt, the thermometer frequently ranges from 110° to 115° in the shade during two or three hours of the day; the nights, on the other hand, are cool and invigorating. Mr King remarks, "Those who take up their residence in the valleys which are situated between the great plain of the Sacramento and San Joaquin and the coast range of hills, find the climate, especially in the dry season, as healthful and pleasant as it is possible for any climate to be which possesses sufficient heat to mature the cereal grains and edible roots of the temperate zone."

Westward of the rivers Sacramento and San Joaquin, the soil is chiefly dry and unproductive; but on the east side the country is well-watered and luxuriantly fertile, being intersected by numerous fine streams, and wooded principally with white oaks. The lowest hills of the Sierra which line the valley present a woodland country diversified with undulating grounds and pretty vales. Near the Tulare lakes, and on the margins of the Sacramento and San Joaquin rivers, the surface is composed of level plains, gradually changing into undulating land toward the mountains. The region from the coast range to the ocean has long been the seat of numerous missions; and around these, generally situated in the most lovely vales, agriculture has converted the country into a perfect garden. All the cereals of temperate regions are cultivated, and the olive and vine grow luxuriantly. Wild oats grow in great profusion along the coast, and as far inland as the sea-breeze has any material influence. The grasses are very luxuriant and nutritious, affording excellent pasture. As the heat and drought of summer are excessive, artificial irrigation, where employed, greatly increases the natural fertility of the soil.

California.

The diversities of climate and soil in different parts of the state render its vegetation of a very heterogeneous character—from the luxuriant productions of the tropics, to the stunted and scanty productions of the frozen regions. Of the pine and oak there are several noble and useful varieties; one of the former is occasionally found growing to the height of 240 feet, with a girth at the base of nearly 60 feet: its seeds are as large as a good-sized bean, and furnish a common article of food to the Indians, who collect large quantities of them in the autumn, and pound them into a kind of cake, which is baked on heated stones. Another variety of the pine is frequently found 110 feet high, and from 10 to 12 feet in diameter. The white oak grows on the low and level parts of the country. It is not generally a large tree, being from 40 to 50 feet high, and from 2 to 3 feet in diameter at the base. It is in some places very abundant. The *Quercus nivalis* is found on the prairies, river banks, and lower hills, and is 4 or 5 feet in diameter, with branches of corresponding dimensions, extending horizontally from the trunk. The *Quercus virens* grows only on the highlands, and is from 60 to 70 feet in height, and from 2 to 5 in diameter. The maple, ash, beech, and chestnut, in several varieties, compose a great part of the forests. The flowering shrubs and plants of California are of great variety and beauty. A species of currant (*Ribes speciosum*), with its long crimson stamens and dark-green leaves, is one of the most beautiful of the flowering shrubs, and is exceedingly abundant in some localities. In many places are found several species of *Mimulus*, one of which is from 3 to 4 feet in height, and very beautiful. The coast abounds with various species of *fuci*.

The animal kingdom of California includes several species of bear, the raccoon, American badger, otter, wolf, fox, cougar, lynx, weasel, ermine, mink, martin, skunk, beaver, musk-rat. Large herds of elks are often seen, and other species of deer are common. The mountain sheep is also common. This animal in its general appearance resembles the domestic sheep, but is much larger, and is covered with a coarse short hair of a dingy brown colour, which can scarcely be called wool. Hares, rabbits, squirrels, marmots, as well as rats and mice, are very abundant in all parts of the country.

The feathered tribes are not found in great variety in California. Among these is the great vulture (*Sarcoramphos Californianus*), which is found along the coast: it is of a brownish-black colour, solitary in its habits, rapacious, and of enormous size, being, when full grown, about 4 feet 8 inches from the beak to the extremity of the tail, and from 9 to 10 feet from tip to tip of its wings. The Turkey buzzard is found, though not frequently; but the black vulture is common in all parts of the country. The golden and whiteheaded eagles, and several species of hawk, are found here, as well as ravens, magpies, jays, woodpeckers, crossbills, larks, robins, swallows, &c. In some parts of the south humming-birds are numerous. American grouse are very plentiful, and in great variety. The bays, inlets, and rivers, swarm with water-fowl; and the lowlands near the outlets of some of the streams are most abundant in geese, ducks, widgeons, teal, cranes, curlews, snipes, &c. The swan is the largest swimming bird of the country. The white pelican is frequently met with on the coast.

The waters of California afford a great variety of fish. Salmon are found in almost incredible numbers in all the rivers and streams connected with the sea. Sturgeons, some of them from 8 to 10 feet in length, porpesses, mackerel, halibut, pilchard, skate, turbot, bonito, &c., are common in various parts. The shell fish are plentiful and valuable, as oysters, mussels, &c.

Though the gold mania in California dates only from 1848, yet the existence of that metal in the country has been long known to travellers. Richard Hakluyt, who accompanied Drake in his expedition in 1577–79, in describing this region, says, "There is no part of earth here to be taken up wherein there is not a reasonable quantity of gold and silver." Captain George Shelvock, who visited the country in August 1721, states, that "The eastern coast of that part of California which I had sight of appears to be mountainous, barren, and sandy; but, nevertheless, the soil about Puerto, Segure, and very likely in most of the valleys, is a rich black mound, which, as you turn it fresh up to the sun, appears as if mingled with gold dust, some of which we endeavoured to wash and purify; but though we were a little prejudiced against the thought that it should be possible that this metal should be so promiscuously and universally mingled with common earth, yet we endeavoured to cleanse and wash the earth from some of it; and the more we did the more it appeared like gold." "It is very probable that this country abounds in metals of all sorts, although the inhabitants had no utensils or ornaments of any metals whatever, which is no wonder, since they are so perfectly ignorant in all arts." Antonio de Alcedo, in his *Diccionario Geografico Historico de Las Indias Occidentales o America*, Madrid, 1786–89, as translated by Thompson, says, "All the ravines, and even plains (of California) contain gold scattered up and down the alluvious land. *Pepitas*, lumps of pure gold of the weight of from two to three kilogrammes (from 5 lb. to 8 lb. troy) have been found there." An article in Hunt's *Merchants' Magazine* for April 1847, by Mr Sloat, who was there in 1845 or 1846, states, that from all the information he was enabled to obtain during his stay, there is not the least doubt that gold, silver, quicksilver, copper, lead, sulphur, &c. are to be found in all that region; and adds, "I am confident that when it becomes settled (as it soon will be) by Americans, that its mineral developments will greatly exceed in richness and variety the most sanguine expectations."

The *Gold Region* of California is between 400 and 500 miles long, and from 40 to 50 miles broad, following the line of the Sierra Nevada. It embraces those extensive ranges of hills which, rising on the eastern border of the plain of the Sacramento and San Joaquin, and extending eastward from 50 to 60 miles, attain an elevation of about 4000 feet, and terminate at the base of the main ridge of the Sierra Nevada. Farther discoveries will probably extend the area of this region.

It is watered by numerous rivers and streams, which take their rise in the Sierra Nevada, and after flowing through the hills at the foot of that range enter the Sacramento and San Joaquin. The principal rock formation in these hills is talc slate; above it, and sometimes penetrating to a great depth, is quartz rock, which however does not cover extensive tracts of country, but occurs massive and in veins, and is found in fragments scattered on the surface. Gold is found only in particular localities in the bars and shoals of the rivers, in ravines, and in what are called the "dry diggings." The rivers in their courses coming in contact with the quartz containing gold, by constant attrition wash out the gold in small particles, which are afterwards found among the sand and gravel of their beds at those places which are left exposed in the dry season.

The dry diggings are places where veins of quartz containing gold have cropped out and been disintegrated, crumbled to fragments, gravel, and dust, by the action of water and the atmosphere. The gold has been left in pieces of all sizes from one grain to several pounds in weight. A very large proportion of the pieces of gold found in these situations have more or less quartz adhering to them. This gold, not having been exposed to the attrition of a strong current of water, retains in a great degree its original conformation. These diggings, in some places, extend over valleys of considerable extent, which have the appearance of an alluvion of decomposed quartz and slate, earth, and ve-

California. getable matter, formed by washings from the adjoining hills. Several vein mines have also been discovered in the quartz, from which numerous specimens have been taken. In these veins the gold, which is generally alloyed with silver, is combined with the quartz in all imaginable forms and degrees of richness. The grain gold of California averages as follows:—Gold, 90·33; silver, 6·90; oxide of iron, 1·08; earthy matter, 1·69; = 100. The rivers present very striking, and it would seem conclusive, evidence respecting the quantity of gold remaining undiscovered in the quartz veins. The latest news from California state that the exports of gold recorded at the custom-house amounted, in 1853, to $67,873,505. The whole yield for that year is calculated at nearly $70,000,000; and in five years and ten weeks to the end of 1853, the quantity produced is estimated at $260,000,000. There are now 125,000 persons engaged in mining. During this year they have prosecuted their great enterprise with industry and skill—have made canals, built aqueducts, turned rivers from their beds, tunnelled the hills, &c. New machinery and new methods have been employed—amongst them, that of washing the ores by water thrown from a great height. Comparatively few new mines have been discovered, but some old ones have been found richer than was expected. The valley of the Klamath has been most attractive, and has been more developed than any other part of the state. Quartz-mining makes but little progress. Various other branches of industry are carried on successfully. There are probably 80,000 persons engaged in cultivating the soil; but labour being very dear, roads bad, and communication altogether very imperfect, farming has not been so profitable as mining. Trade has been prosperous. The assessor's roll of St Francisco showed in August a valuation of $30,000,000. The navigation was as follows, as derived from the books of the custom-house of the entrances and clearances for 1853 to the 27th December:—

	Entered from.		Cleared for.	
	Vessels.	Tonnage.	Vessels.	Tonnage.
Domestic Ports	449	351,144	750	164,124

Total for 1851 ...	847	245,566	1315	423,063

The quicksilver mines of California are believed to be numerous, extensive, and very valuable. The best known of these is that near San Jose. The cinnabar ore lies near the surface, is easily procured, and believed to be remarkably rich. Discoveries of other mines are reported, but no certain information respecting them has been made public. It is believed, however, that quicksilver will eventually be found in sufficient quantities for all the purposes of extensive gold-mining operations, if not for export. It is also believed that California is rich in silver, copper, lead, iron, and coal. At a short distance from Monterey, a silver mine has been discovered which affords a very rich ore; and bituminous coal is abundant in the neighbourhood of San Francisco.

The population of Upper California was estimated by Humboldt in 1802 at no more than 16,862, of whom 15,562 were converted Indians; and, as already mentioned, by Forbes in 1831 at 23,025. In 1847 the white inhabitants amounted only to about 16,000. From the state of the country, any census reports must necessarily be very incomplete. That of 1850, which gives the population at 117,538, can scarcely be considered an approximation. General Douglass is probably more nearly correct in estimating the population in the autumn of that year at 180,000. W. Van Voorhies, secretary of state, in his report upon the census of 1852, dated 25th January 1853, says, "Immediately after the adjournment of the last legislature, active measures were commenced, which have been prosecuted up to the present time, for the purpose of making a correct and complete exhibit of the population and resources of the state. This object, however, has been but imperfectly accomplished, in consequence in some degree of the intrinsic difficulties of so complicated and extensive an undertaking in a new and comparatively unknown country, but mainly owing to the mixed, unsettled, and fluctuating character of our population, the difficulty of thoroughly exploring the mountain counties, the hostile tribes of Indians infesting some sections, and the mistaken supposition on the part of many that the business of the census agent was in some way connected with taxation. Believing that the occasion of taking this census afforded an opportunity (which might not be again soon enjoyed) of procuring interesting geographical, geological, mineralogical, and other information pertaining to the natural curiosities and features of the state, I embraced it, and instructed each of the census agents to collect whatever of notable objects might come within their observation. These instructions, not having been received by some of them until they were far advanced in their labour, were only carried out in a portion of the counties." "A large number of the most important counties having failed to furnish any information on these subjects, we are left to conclude that much of the most useful and interesting matter in this branch remains yet to be developed." The population of the state as returned amounted to 224,435; no returns, however, had been made for the county of El Dorado, which is admitted to be one of the most populous and productive in the state; estimating it therefore at 40,000, the entire population would amount to 264,435. "There can be no doubt, however," says the secretary, "that, in consequence of the difficulties previously mentioned, not more than five-sixths of the whole population of the state has been taken. The reports of all the census agents who have made returns set forth the fact of their inability to obtain the whole population of their respective counties. Adding then one-sixth to the population returned, and that estimated for El Dorado county, gives the population of the state at 308,507, which is believed to be about correct."

The following particulars of the various counties are extracted from the census report of 1852:—

Butte County extends 100 miles from north to south, and 250 from east to west. The Butte mountains, from which the county takes its name, are situated on the Sacramento. Of these, Mount Hood, in the northern part of the county, is the most striking, towering far above its neighbours, and presenting an apex covered with perpetual snow. The scenery is grand and picturesque. It has many beautiful and fertile valleys well fitted for pasture and agriculture; water is abundant, and irrigation easy. Majestic pines and cedars occupy the mountains. Platina and iron abound in all the mining districts, but not in sufficient quantities to require machinery. Fine lead ore is found on the head waters of the Middle Fork. Quicksilver is abundant, and silver is found in small quantities. There are many fine sites for mills:—fifteen quartz mills, eleven water, and three steam saw-mills, are in operation. The cultivated land amounts to 2144 acres. Pop. 8572, of which the whites number 6174 males, and 206 females.

Calaveras County.—The principal rivers are the Stanislaus, on its southern boundary; the Moquelumne, equidistant from its northern and southern boundaries; and the Calaveras, 8 miles south of the Moquelumne; taking their rise in the Sierra Nevada, and falling into the San Joaquin. The most important town is Moquelumne Hill, situated 1½ miles south of the Moquelumne river, and having a large trade; besides which it contains a number of small towns or camps. Pop. 20,192; whites, 17,069 males and 973 females.

Colusi.—Though not a mining county, yet gold has been found within its limits. Cultivated land, 1962 acres. Pop. 620; whites, 400 males and 63 females.

Contra Costa County contains limestone of excellent quality; gypsum is found in one place; and excellent building

stone and red freestone have been discovered. There are a number of saline springs; and sulphureous springs, mostly tepid, are abundant. Many springs, and plenty of water for cattle. The towns are, Martinez (the seat of justice), Oakland, and Squatterville. Cultivated land, 9093 acres. Pop. 2745; whites, 1937 males and 550 females.

Klamath County.—A great part of this county is eminently fitted for agriculture. The rivers Klamath, Trinity, and Salmon, all abound in gold. The Salmon mountain, between the Salmon and Klamath, is covered with snow for nine months in the year; and Mount Prospect, on the Klamath, rising 5000 feet above the sea. Cultivated land, 109 acres. Pop. 530; whites, 458 males and 9 females.

Los Angeles County is well watered and wooded, and capable of producing every variety of vegetables. San Bernardino valley, 60 miles east of Los Angeles city, is rich and well watered. It is occupied by Mormons. San Bernardino rises to a great height. Mount San Gorgonio is 20 miles S.E. of the preceding, on the boundary between this county and the desert. The climate is remarkably salubrious and genial. The rivers are Santa Ana, San Gabriel, Rio de Los Angeles, and tributaries. Port San Pedro has good anchorage, and is perfectly safe, except during the prevalence of the S.E. winds in winter. Limestone and building-stone are found in abundance. There are also a number of salt springs. A spring of petroleum, six miles from Los Angeles, covers about two acres of ground. *Placer* gold is found; and 200 miles from Los Angeles there is a vein of quartz-bearing gold. There are great facilities for agriculture, which, however, has been neglected. The mission lands are principally cultivated under the direction of the priests. Hemp and tobacco, though not grown now, were formerly raised in considerable quantities. Cotton and sugar-cane succeed well. There are many fine orchards producing almost all tropical fruits. Cultivated land, 5587 acres. There are 105 vineyards (all, except twenty, at the city of Los Angeles). Pop. 7831; white, 2496 males and 1597 females.

Marin.—Although not a mining county, yet gold-bearing quartz, *placer* gold, silver and copper ores, have been found. Iron ore is abundant. Cinnabar, steatite or soapstone, lime, asphaltum, marble, brick clay, and granite, are abundant and of good quality. The towns are, San Rafael (the seat of justice), Saucelito, and Corta Madera. One-half of the land is susceptible of cultivation, and the other well adapted for grazing. Garden vegetables of all kinds are abundant. Cultivated land, 1250 acres. Marin possesses four large steam saw-mills. Pop. 1036; white, 652 males and 160 females.

Mariposa County.—Here agriculture, though still in its infancy, has lately been making rapid advances, and abundant proofs are shown of its adaptation to all kinds of produce. Wild oats, clover, and other rich grasses are abundant in the San Joaquin valley, and the lower hills of the Sierra Nevada. Wild horses and game of all kinds are plentiful. There are extensive forests of red wood, cedar, and pine, along the lower hills of the Sierra Nevada There are two saw-mills in operation, and many desirable sites for others. The San Joaquin passing through this county abounds in salmon and other kinds of fish, and is navigable for moderate-sized steam-boats to within a few miles of Fort-Miller. The Mercede river also abounds in fish. Between the San Joaquin and the Mercede are numerous streams of minor importance, rising in the lower hills of the Sierra Nevada, and affording supplies of water for mining purposes. Gold is abundant. There are six quartz mills in operation, and many erecting. Immense deposits of gold are known to exist in the beds of the San Joaquin and Mercede rivers, and other streams, but could only be obtained by a heavy expenditure of capital and labour. Minerals of every kind are found. The extent of the gold region is perhaps a hundred miles in breadth, extending back into the unexplored regions. The finest kind of marble exists at the North Fork of the Mercede and elsewhere. There are various kinds of mineral springs in different parts. Fort-Miller is situated at the entrance of the San Joaquin river into the plains. Pop. 8969, of whom 2782 are Americans.

Mendocino County.—Pop. 416; white, 169 males and 28 females.

Monterey County has an average length of 90, and a width of 38 miles, with an area of 420 square miles. It is divided into three valleys, known as the San Juan, Salinas, and Carmel. It is watered by the Salinas or San Buenaventura, and other streams. In the upper end of the Salinas valley are sulphureous springs. Gold has been found at San Antonio and in Carmel valley; silver has also been found in small quantities; much of the land is rich and productive. Stock-raising is extensively carried on. Cultivated land 3117 acres. Pop. 2728; white, 1152 males and 791 females.

Napa County has 10,584 acres in cultivation. Mount St Helen, at the head of the valley of Napa, is 3500 feet in height. Gold is found, but not in sufficient quantities to encourage mining. A mine of quicksilver, about 14 miles above the town of Napa, is supposed to be very rich. The country is celebrated for its medicinal springs. The Napa river rises in the northern part of the Napa valley, and flowing in a southern direction, empties itself into Pablo bay. It is navigable for vessels of five feet draft for 12 miles above its mouth. Las Putas rises in the north part of the county, runs in an easterly direction through the beautiful Berryessa valley, thence through the mountains into the Sacramento valley, and afterwards loses itself in the Tule marshes. Napa city stands on the west bank of the river of that name, about 12 miles from its mouth. Pop. 300. Suscol is on the same river, about 6 miles from its mouth. The hot sulphureous springs in the mountains about 70 miles above Napa city in a northerly direction, are from 1 to 8 or 9 feet in diameter, and constantly in a boiling state, the water being ejected to the height of ten or fifteen feet. Hundreds of fissures in the sides of the mountain emit strong currents of heated vapour, making deep hissing noises. Pop. 2116; white, 523 males and 252 females.

Nevada County has 1587 acres in cultivation. There are 33 quartz mills. Pop. 21,365; white, 12,448 males and 920 females.

Placer County has 679 acres in cultivation. Pop. 10,784, mostly engaged in mining; of these, the whites number 6602 males and 343 females.

Sacramento County is rich in cereal and vegetable productions. Pop. 12,589; white, 9457 males and 1739 females.

San Joaquin County is essentially agricultural, being situated in the heart of a fertile valley hundreds of miles in extent, with fine grazing; 4000 acres are cultivated. Mining is but little carried on. The roads and bridges are excellent. The chief town is Stockton, with a population of 3000, one of the principal cities of the state, on the Stockton slough or channel (about three miles from its junction with the San Joaquin), navigable for vessels at all seasons; the streams are San Joaquin, Moquelumne, Calaveras, Stanislaus, and Dry creek. Settlers are rapidly establishing themselves on the banks of these rivers. Pop. 5029; white, 3582 males and 987 females.

San Luis Obispo County.—The mineral, agricultural, and commercial resources of this county are great. It has rich silver mines, and a fine coal-mine. Lime rock is abundant; copper and iron are supposed to exist on the bay of San Simeon. There are many large petroleum springs, and a warm sulphureous spring about ten miles south of San Luis Obispo. Wild horses are found in large numbers on the plains in the N.E. part of the county. The cultivated land is 2538 acres. Pop. 984; white, 331 males and 163 females.

Santa Clara County has 19,066 acres in cultivation. Pop. 6664; white, 5813 males and 2062 females.

Santa Cruz County has 5472 acres of cultivated land, and 1219 inhabitants; white, 723 males and 374 females.

Santa Barbara County has 2131 inhabitants; whites, 834 males and 682 females. It has 699 acres in cultivation. The soil is very productive, especially where it admits of irrigation. The coast range of mountains here attains the height of 4000 feet; one of these is a volcano. The rivers are, the Santa Clara, the San Buenaventura, and the Santa Inez. The waters of the coast abound in many species of excellent fish. A bed of large and well-flavoured oysters, 150 yards in length, 25 feet wide, and 2 or 3 feet thick, has been discovered near Santa Barbara. The islands are much frequented by otters, bottle-nose and other seals, and beavers. There is a hot sulphureous spring, temperature above 100° Fahr., near the village of Santa Barbara. In the neighbourhood are one or two petroleum springs. For leagues along the coast the sea throws up bitumen. The Salinas afford abundance of salt, which is gathered in August and September. Gold is found in the southern part of the county.

California.

San Diego County has 304 acres of cultivated land. Pop. 2932; white, 397 males and 140 females.

San Francisco County.—The soil is rich and productive, and farming is rapidly extending, but its agricultural resources have as yet been little developed. Cultivated land 1297 acres. San Francisquita creek, dividing this county from Santa Clara, rises in the Sierra Morena, runs eastward, and empties itself into San Francisco bay. Gold in small quantities has been found in this creek. Of the Sierra Morena or Brown Mountains, the most remarkable commence at a point about 10 miles south of San Francisco, and run along the coast until they unite with the range of the same name in the county of Santa Clara. These mountains, which rise above 2000 feet, protect the inhabitants of the valley from the coast winds. Pop. 36,151; white, 30,156 males and 5375 females. The city of San Francisco has 34,876 inhabitants; the whites numbering 29,166 males and 5154 females.

Shasta County has numerous mines. There is not a river, creek, or ravine, that does not contain gold. The principal stream is the Sacramento river; besides which there are numerous small streams and creeks that are particularly valuable for the purposes of the miner. There are numerous mineral springs strongly impregnated; the most celebrated is the soda spring, near the Sacramento river, 60 miles north of Shasta city; and the salt springs, 12 or 15 in number, which would produce salt enough to supply the state. There are 908 acres in cultivation. Pop. 4050; white, 3448 males and 252 females.

Sierra County has 168 acres of cultivated land. Saddle Peak rises to the height of 7200 feet; Table Mountain 8000; and Buttes, at the head of South Fork, to the height of 9000 feet. The towns are, Downieville, with 810 inhabitants; Pine Grove, with 504; Windsor, with 210; Coxe's and Snake Bars, with 346; and Goodyear's Bar, with 356 inhabitants. Pop. 4855; white, 3630 males and 62 females.

Liskiyou County has 309 acres in cultivation. Pop. 2240; white, 1874 males and 82 females.

Solano County.—In the eastern part of the county is a double mountain peak very conspicuous at the head of Green valley; the next in magnitude is a double peak between Green valley and Suscol. Puta river, 10 miles north of Ulattis valley, rises in the mountains, winds through a rich and fertile plain, and loses itself in the extensive Tules which lie between the plains and the Sacramento river. The western part of the county is mountainous, and very interesting; many of the small valleys are well adapted for raising stock. Three large soda springs rise in these valleys. Suscol valley, west of the Suscol hills, runs from the city of Vallejo to the northern part of the county, is 8 miles in length and 3 in breadth, and washed through its entire length by Napa bay. The valleys form an interesting portion of this county; they are well adapted for farming, producing wild oats of luxuriant growth. Cultivated land 5049 acres. Pop. 2835; white, 2324 males and 402 females.

Sonoma County has 9387 acres of cultivated land, and 2337 inhabitants, the whites numbering 1309 males and 511 females.

Sutter County has 1401 acres of cultivated land, and 1207 inhabitants, the white population being 590 males and 85 females.

Trinity County has 275 acres in cultivation, and 1764 inhabitants; white pop. 1741 males and 23 females.

Tuolumno County has 1870 acres of cultivated land, and 17,657 inhabitants; whites 15,967 males and 958 females.

Tulare County has 8575 inhabitants; whites, 142 males and 32 females; 8400 Indians.

Yolo County has 1307 inhabitants, of whom 1085 are males and 189 females. Cultivated land, 3846 acres.

Yuba County has 22,005 inhabitants; whites, 16,666 males and 633 females. Cultivated land, 7008 acres. This county is very rich in gold and quicksilver. The principal stream is the Bear river, forming the county boundary line on the south, and falling into the Feather river 31 miles below Marysville; besides which there are numerous small streams and creeks, which abound in gold. On the Middle Yuba is Oregon Hill, which, according to Dr Frost, rises to the height of 2800 feet. The towns and villages are, Marysville on the Yuba river, 1 mile above its confluence with the Feather river, pop. 4500; Ousley's Bar, 13 miles above Marysville, pop. 390; Kennebeck, 14 miles above Marysville, pop. 120; Long's Bar, 16 miles above Marysville, pop. 450.

El Dorado County, from which no returns have been obtained, is supposed to have a population of about 40,000, of whom about 30,000 are whites.

California || Caliga.

California sends two members to the congress of the United States, and two members to the house of representatives. The legislative power is vested in a general assembly, consisting of a senate of sixteen members, elected for two years; and a house of representatives of thirty-six members, elected for one year. The sittings of the general assembly are held annually. The supreme court consists of a chief-justice and two associate justices. It has appellate jurisdiction where the matter in dispute exceeds 200 dollars, and where the legality of certain acts is questioned, as well as in certain criminal cases. The justices are elected by the people for six years, and are so classified that one goes out of office every two years. The senior judge in office is the chief justice. The district courts have jurisdiction in law and equity where the amount in dispute, exclusive of interest, exceeds 200 dollars. The constitution provided that at the first election the judges should be chosen by the legislature, but afterwards by the people, and for a term of six years. A county judge is elected in each county for four years to act as judge of probates, to hold the county court, and with two justices of the peace to hold courts of session for criminal business. Clerks of courts, district attorneys, sheriffs, coroners, &c., are elected by the people.

The constitution provides for the election of a superintendent of public instruction, to hold office for three years, and that the legislature shall establish a system of common schools to be taught at least 3 months in each year. A superintendent has been elected, but as yet there are but few schools. The capital of the state is, for the present, Vallejo, but the question of its future locality is still unsettled.

California promises at no distant day to be one of the first states in the Union. The bold and enterprising character of her present inhabitants cannot fail of rendering it a great, wealthy, and powerful state. In the ordinary elements of wealth and power, it is not behind the older states, while it far surpasses the most favoured in her inexhaustible supplies of the precious metals. In many of its productions it is (as shown by the census of 1852) already in advance of many of the other states. Though agriculture has yet been comparatively little attended to, the fact that it excels most of them in the productions of the soil shows the fertility and productiveness of the land. The counties of Yolo, Trinity, Sutter, Santa Cruz, San Diego, Sacramento, and Nevada, have reported merchandise to the amount of $400,000,000. The many interesting geological developments made by the census places this far in advance of all the other states in the variety and importance of its mineral productions.

California, *Gulf of*, an arm of the Pacific Ocean, separating the peninsula of Lower California from the mainland. It lies between Lat. 23. and 32. N. and Long. 107. and 114. W.; and is about 700 miles in length, with a breadth varying from 40 to 150 miles. Its western shores are generally high and rocky, with few places of shelter; its eastern shores are lower and less rocky. It contains numerous islands; and at its northern extremity receives the rivers Colorado and Gila.—See California, Lower.

CALIGA, in *Roman Antiquity*, the strong and heavy shoe of the common soldier. It was made in the sandal fashion, without upper leather to cover the superior part of the foot, though otherwise reaching to the middle of the leg, and fastened with thongs. The sole was of wood, like the sabot of the French peasants, and studded with *clavi* or nails, which by some are supposed to have been of considerable length in the shoes of the scouts and sentinels; whence they were called *caligæ speculatoriæ*—as if, by elevating the wearer, they extended the range of his view. Others, however, suppose that the *caligæ speculatoriæ*

were made soft and light. The emperor Caligula received his cognomen from having originally served in the army as a common soldier. According to Du Cange, a sort of *caliga* was also worn by monks and bishops when they celebrated mass pontifically.

CALIGATI, an appellation of the common soldiers in the Roman armies, derived from *caliga*, a peculiar kind of shoe worn by them. See CALIGA.

CALIGULA, the Roman emperor, A.D. 37–41, was the son of Germanicus and Agrippina, and was born A.D. 12. He began his reign with every appearance of becoming the real father of the people; but eight months after he assumed the purple, he was seized with a fever, which probably weakened his mental faculties; for his disposition totally changed, and he became a sanguinary and licentious tyrant. After having murdered many of his subjects with his own hand, and caused others to be put to death without trial, he was assassinated by a tribune of the people as he was leaving the amphitheatre. See ROMAN HISTORY.

CALIPH, or KHALIF, the sovereign dignitary among the Mohammedans, vested with absolute authority in all matters relating to religion and civil policy. In the Arabic it signifies *successor* or *vicar;* the caliphs bearing the same relation to Mohammed that the popes pretend they bear to St Peter. It is at this day one of the titles of the Grand Seignior or Sultan, as successor of Mohammed; and of the Sophi of Persia, as successor of Ali. One of the chief functions of the caliph, in his quality of imaum or chief priest of Islamism, was to begin the public prayers every Friday in the chief mosque, and to deliver the *khootba* or sermon. In after times they had assistants for this latter office; but the former was always performed by the caliph in person. The caliph was also obliged to lead the pilgrims to Mekka in person, and to march at the head of the armies of his empire. He granted investiture to princes, and sent swords, standards, gowns, and the like, as presents to princes of the Mohammedan religion; who, though they had thrown off the yoke of the caliphate, held of it as vassals. The caliphs usually went to the mosque mounted on mules; and the sultans Selgiucides, though masters of Baghdad, held their stirrups, and led their mules by the bridle some distance on foot, till the caliphs gave them the sign to mount on horseback. At a window of the caliph's palace there always hung a piece of black velvet twenty cubits long, which reached to the ground, and was called the *caliph's sleeve;* which the grandees of his court kissed daily with great respect. After the destruction of the caliphate by Hulaku, the Mohammedan princes appointed a particular officer in their respective dominions to sustain the sacred authority of caliph. In Turkey this officer is called *mufti*, and in Persia *sadne.*

CALIPHATE, the office or dignity of caliph. The successions of caliphs continued from the death of Mohammed till the 655th year of the Hegira, when Baghdad was taken by the Tartars. After this, however, there were persons who claimed the caliphate, as pretending to be of the family of the Abassides, and to whom the sultans of Egypt rendered great honours at Cairo, as the true successors of Mohammed; but this honour was merely titular, and the right allowed them only in matters of religion; and though they bore the sovereign title of *caliphs*, they were subjects and dependents of the sultans. In the year of the Hegira 361, a kind of caliphate was erected by the Fatemites in Africa, and lasted till it was suppressed by Saladin. Historians also speak of a third caliphate in Yemen or Arabia Felix, erected by some princes of the family of the Jobites. The emperors of Marocco assume the title of *grand scherifs*, and pretend to be the true caliphs, or successors of Mohammed, though under another name.

CALIPPIC PERIOD. See CALENDAR, p. 79.

CALIPPUS, or CALLIPPUS, an astronomer of Cyzicus, who invented the period or cycle of 76 years, which is called after his name the *Calippic.* He went to reside at Athens, where he became acquainted with Aristotle, and engaged with that philosopher in rectifying the discoveries of Eudoxus. See CALENDAR, p. 79.

CALISTHENICS (καλος beautiful, σθένος strength), the science or practice of exercising the body and limbs for the purpose of promoting strength and graceful deportment.

CALITRI, a town of Italy, in the Neapolitan province Principato-Ulteriore, near the river Ofanto. Pop. about 5000.

CALIXTINES, the followers of George Calixtus, a learned Lutheran divine, and professor at Helmstadt, who died in 1656. Calixtus opposed the opinions of St Augustin on predestination, grace, and free will, and endeavoured to form a union among the various members of the Romish, Lutheran, and Reformed churches; or at least to unite them in the bonds of mutual forbearance and charity.

CALIXTINES, a sect in Bohemia, derived from the Hussites, about A.D. 1420. They maintained that the use of the cup was essential to the eucharist; and hence their name, from *calyx* a cup.

The Calixtines were not ranked by Romanists in the list of heretics, since in the main they still adhered to the doctrines of Rome. The reformation they aimed at was comprehended in these four demands: 1, that the cup should be restored to the laity; 2, that criminal clerks should be subject to punishment; 3, that the clergy be reclaimed from the pursuit of wealth and power; 4, that the word of God be preached to the people in purity and simplicity.

CALIXTUS, the name of three different popes or bishops of Rome. The first ascended the chair of St Peter A.D. 219; the second in 1119; the third in 1455.

CALIXTUS, *Georgius*, a celebrated Lutheran divine, born at Middelburg in Holstein in 1586. After studying at Helmstadt, Jena, Giessen, Tübingen, and Heidelberg, he had an opportunity of travelling through France and England, where he became acquainted with the leading reformers, and saw the different forms which the Reformed church had assumed. On his return he was appointed professor of divinity at Helmstadt by the Duke of Brunswick, who had admired his abilities in a contest which he had when a young man with the Jesuit Augustine Turrianus. After becoming a master of arts he published a book, *Disputationes de Præcipuis Religionis Christianæ Capitibus*, which provoked the hostile criticism of several learned men; and on his elevation to the professorship he published his *Epitome of Theology*, and soon after his *Epitome of Moral Theology*, which gave so great offence as to induce Statius Buscher to charge him with a secret leaning to Romanism. Scarcely had he refuted the accusation of Buscher, when, on account of his intimacy with the Reformed divines at the conference of Thorn, and his desire to unite them with the Lutherans, a new charge was preferred against him, principally at the instance of Calovius, of a secret attachment to Calvinism. The disputes to which this gave rise, known in the church as the Syncretistic controversy, lasted during the whole lifetime of Calixtus, and distracted the Lutheran church, till a new controversy arose with Spener and the Pietists of Halle. Calixtus died in 1656. He was among the first who attempted to systematize theology, but was too much fettered by the method of Aristotle.

CALLAN, a market-town in the county of Kilkenny, Ireland, 82 miles S.S.W. from Dublin. N. Lat. 52. 33., W. Long. 70. 23. It stands on a level *strath*, watered by the King's river, a tributary of the Nore, and was a walled town of considerable strength, till dismantled by Cromwell. The smaller portion of the town stands on the north side of the river, and contains the remains of an Augustinian friary, connected by a bridge with a chapel and convent, on the opposite side. On the southern side there are no buildings

of importance, except the parish church—an ancient edifice—and the Roman Catholic chapel. It is laid out in four principal streets, which intersect each other at right angles. Callan was once a municipal and parliamentary borough, but was disfranchised at the Union. It gives the title of Viscount to the Fieldings, Earls of Denbigh. Pop. in 1841, 3111; in 1851, 2368, besides 2102 inmates of the workhouse.

CALLANDER, a village on the Teith, Perthshire, 30 miles W.S.W. from Perth. It is chiefly frequented by tourists on their way to the Trosachs, and contains several good hotels. The population of the parish, which includes the villages of Callander and Kilmahog, in 1851 was 1716.

CALLAO, a town of Peru, six miles west from Lima, of which it is the port. Lat. 12. S., Long. 77. 12. W. It is built on a flat point of land in the recess of a spacious bay formed by the isles of San Lorenzo and Fronton, and communicates with Lima by an excellent carriage road. The original site of the town is now covered by the sea, and the ruins of the houses which were demolished by an earthquake in 1746 are still visible in calm weather in the bay. The modern town consists chiefly of houses made of wicker-work, and plastered with mud, stronger buildings being rendered unnecessary by the mildness of the climate, and dangerous from the frequency of earthquakes; but the fortifications and government buildings are both massive and well-mounted with cannons. Callao was the last stronghold in possession of the Spaniards which held out against the insurgent patriots, but was compelled to surrender in 1821. The bay of Callao is well sheltered, and affords the best anchorage on the Peruvian coast. Below the city a mole has been constructed, at which vessels of considerable burden may discharge their cargoes. The trade of Callao, consisting of exports and imports, is carried on chiefly with Great Britain and the Western States of America. The principal exports are bullion, copper, cotton, soap, bark, Vicuna and Alpaca wool, and hides; the imports are cotton, linen, and woollen stuffs, hardware, fish, flour, indigo, spices, timber, &c. The declared value of British imports alone in 1846 was L.820,535. Pop. estimated at about 20,000.

CALLAO, so called by its inhabitants, but more generally known to Europeans under the name of Campello, lies off the coast of Cochin-China, about eight miles to the eastward of the mouth of a considerable river, on the banks of which stands the town of Faifoo, a place of some note. The only inhabited part of the island is on the S.W. coast, upon a slip of ground rising gently to the east. This small spot, when the Chinese embassy visited the island, was beautifully laid out with neat houses, temples, clumps of trees, and small hillocks richly decorated with shrubbery. The houses, which amounted to about sixty, were very clean and well-kept; a few were built with stone, and covered with tiles. The depth of water in the bay and roadstead is sufficient for ships of any burden; and there is perfect shelter from every wind except the S.W. It is thirty miles S.E. of the harbour of Turon. The extreme points of the island lie in Long. 108. 30. E., and Lat. 15. 53. N.

CALLCOTT, JOHN WALL, a celebrated composer of music, was born at Kensington in 1776. When nineteen years of age he was admitted bachelor of music at Oxford, and having studied under Haydn for about a year, he obtained the degree of doctor in 1800. Besides his *Musical Grammar*, he composed a great number of original works, and is especially celebrated for his glees. They were collected and published after his death, which took place in 1821.

CALLCOTT, *Sir Augustus*, an eminent landscape-painter, brother of the preceding, was born in 1779. His small pictures possess a clearness, depth, and breadth which have seldom been attained by any of the British school. He was admitted an associate of the Royal Academy in 1807, and elected an academician in 1810. His merits as an artist, and his estimable character, obtained for him the honour of knighthood in 1837; and in 1844, a few months before his death, he was appointed conservator of the royal pictures. He married Mrs Maria Graham, well known for her travels in India and America. She predeceased him by a short time.

CALLICRATES, a Lacedæmonian sculptor, who made an ivory chariot that might be concealed under the wing of a fly, and an ant of the same material, so small that its limbs could not be distinguished. Ælian justly censures him for exerting his talents on such useless things. (Ælian. *V. H.* i.; Plin. *H. N.* vii. 21, xxxvi. 5.)

CALLIGRAPHUS (κάλλος beauty, γραφω I write) anciently denoted a copyist or scrivener, who transcribed fair and at length the notes or minutes taken by the notaries. The minutes of acts, &c., were always taken in a kind of short-hand, by which means the notarii (the σημειογράφοι and ταχυγράφοι of the Greeks) were enabled to keep pace with a speaker, or person who dictated. These notes were copied out at length by the *calligraphi*.

CALLIMACHUS, a celebrated Greek poet, was a native of Cyrene, and a descendant of the illustrious house of the Battiadæ, whence by Ovid and others he is called Battiades. He flourished under the Ptolemies Philadelphus and Euergetes, and probably succeeded Zenodotus as chief librarian of the famous Alexandrian library, an office he held from about B.C. 260 till his death, which took place about B.C. 240. He was regarded, according to Quintilian, as the prince of Greek elegiac poets. His style is elegant and nervous, yet his excellencies are rather the result of excessive elaboration than of genuine poetic power: hence Ovid (*Am.* i. 15) says of him—*Quamvis ingenio non valet, arte valet.* Perhaps the *Hymn to Apollo* should be excepted from this criticism.

Callimachus was a learned critic and grammarian, and the instructor of Eratosthenes, Aristophanes of Byzantium, and Apollonius Rhodius. He wrote in prose and in verse on a great variety of subjects; but his only existing works are six hymns, seventy-three epigrams, and some fragments of elegies. Of the various imitations of Callimachus by the Roman poets, the small poem by Catullus, *De Coma Berenices*, is the most celebrated. Among the numerous editions of his works the following may be noticed:—By Spanheim, Ultraj. 1697, re-edited by Ernesti, Lugd. Batav. 1761; by Blomfield, Lond. 1815; by Volzer, Lips. 1817.

CALLIMACHUS, an architect and statuary, the inventor of the Corinthian column, was probably a native of Corinth. He is said to have derived the idea of the Corinthian capital from observing an acanthus plant surrounding a tile-covered basket which had been placed over a tomb. His era is uncertain; but as the Corinthian column was used in B.C. 396 by Scopas, the architect of the temple of Athena Alea at Tegea, he must have lived before that time. Though Callimachus worked admirably in marble, he is said to have spoiled his original conceptions by excessive elaboration, which rendered his style artificial. (Plin. *H. N.* xxxiv. 8. s. 19.)

Pliny mentions a painter named Callimachus, who is generally identified with the statuary, though without sufficient authority.

CALLINGAPATAM, a town of Hindustan, on the sea-coast of the Northern Circars, 70 miles N.E. from Vizagapatam. Long. 84. 15. E. Lat. 18. 25. N.

CALLINGER, a strong and celebrated fortress of Hindustan, in the British district of Banda in Bundelcund. Distant S.E. from Banda, 34 miles; S.W. from Allahabad 112 miles; N.W. from Calcutta 607. Lat. 25., Long. 80. 32. It is built of stone on the top of a lofty mountain, is five miles in circumference, and is well supplied with water from several tanks which are inclosed within it. This fort has been often besieged, but generally without success. The celebrated Mahmoud of Ghizne attempted its capture in

1024, but, probably doubtful of the result, permitted himself to be appeased by rich presents, and withdrew. In 1543 Sher Shah, the Afghan who expelled the emperor Humayon from the throne of Hindustan, was slain in attempting to take it. It held out for ten years against Ali Behadur, the Mahratta invader of Bundelcund, who at length died without having made himself its master. At the commencement of the present century it was governed by a commandant appointed by the rajah of Punna, but who subsequently disclaimed the authority under which he served and assumed dominion of the place. His successor caused much annoyance to the British government by affording shelter to the banditti of the country; and in consequence the fortress, early in 1812, was besieged by the British. On the 20th February, the breach being considered practicable, a storming party attempted the ascent of the steep and rugged face of the hill, but though the assailants pushed their enterprise with amazing intrepidity they were repulsed with great slaughter. So intimidated, however, was the garrison by the pertinacity of the besiegers, that its success was followed by overtures for peace; and eight days afterwards the commandant surrendered the fort on condition of receiving an equivalent in lands in the adjacent plain. The elevation of Callinger above the level of the sea is 1230 feet.

CALLINGTON, a market-town in the middle division of the eastern hundred of Cornwall, 7 miles S.S.W. from Tavistock. It has an ancient parish church, and several dissenting places of worship. Callington formerly returned two members to parliament, but was disfranchised by the Reform act. Pop. of parish (1851) 2146.

CALLINO, a town of Italy, in the Neapolitan province Abruzzo Ulteriore, with 1400 inhabitants.

CALLINUS of Ephesus, the earliest Greek elegiac poet, flourished about B.C. 700. One of his elegies has been preserved by Stobæus. (Bergk's *Poetæ Lyrici Græci.*)

CALLIOPE, the muse of epic poetry. She was thus named from the sweetness of her voice, and was the last of the nine sisters. Her distinguishing office was to record heroic actions; and she is represented with a tablet and style, or a roll of paper in her hand. See MUSES.

CALLIPÆDIA, the name of a Latin poem in four books, by Claude Quillet de Chinon, a French abbot, who published it under the fictitious name of *Clavides Lætus.* Its full title is *Callipædia, seu de pulchræ prolis habendæ ratione.* This work was translated into English verse by Nicholas Rowe.

CALLIPHON, an Epicurean philosopher, who is censured by Cicero for maintaining that the union of virtue (*honestas*) with corporeal gratification constitutes the chief good of man.

CALLIRRHOE, in *Ancient Geography* (surnamed *Enneacrunos* from its nine springs or channels), a fountain near Athens, greatly adorned by Peisistratus. There were several other wells in the vicinity, but this was the only running spring. This name was also applied to a considerable stream of hot water, which rises from several springs on the eastern side of the Jordan, and falls, after a short course, into the Dead Sea.

CALLISTEIA, in *Grecian Antiquity,* a Lesbian festival, at which the women assembled in the sanctuary of Juno, where the prize of beauty was adjudged to the fairest. A similar contention took place among the Parrhasians at the festival of Ceres Eleusinia; and there was another among the Eleans, in which the most beautiful man received a complete suit of armour which he consecrated to Minerva; to whose temple, after being adorned with a myrtle wreath and with ribbons, he was accompanied by his friends.

CALLISTHENES, a philosopher of Olynthus, and a relation and pupil of Aristotle, through whose recommendation he was appointed to attend Alexander in his Asiatic expedition, B.C. 334. He had the imprudence to censure the conqueror's adoption of Oriental customs, inveighing especially against the servile ceremony of adoration. Having by the boldness of his censures rendered himself highly obnoxious to the king, he was accused of being privy to a treasonable conspiracy; and after being kept in chains for seven months he died, either by torture, or of a disease arising from excessive obesity. Callisthenes wrote an account of Alexander's expedition, a history of Greece, and other works, all of which have perished.

CALLISTO, in ancient fable, the daughter of Lycaon, king of Arcadia, and one of Diana's attendants. She bore a son, Arcas, to Jupiter, who endeavoured to conceal his amour from Juno by metamorphosing the nymph into a she-bear. In this disguise, through the artifice of Juno, Callisto was slain by Diana; and under the name of Arctos she was placed among the stars. The story of Callisto is variously related by different authors. (See Ovid. *Met.* ii.; Hygin. *Fab.* 176, 177; Apollod. iii.)

CALLISTRATUS, an Athenian orator, whose eloquence and high reputation made so deep an impression on Demosthenes that he abandoned Plato, and resolved thenceforward to devote himself to oratory. On account of the undue influence that Callistratus exercised in the state, he was condemned to death, B.C. 361; and retiring to Methone in Macedonia, he founded, it is said, the city of Datum, afterwards Philippi. Having returned to Athens, he was put to death.

CALLISTRATUS, an Athenian poet, whose works have nearly all perished. He is now only known as the author of the hymn in honour of Harmodius and Aristogeiton, who fell in their attempt to put down the dynasty of the Pisistratidæ at Athens. This ode has been beautifully translated by Thomas Moore.

CALLON, a Greek sculptor, born in the island of Ægina in the first year of the 65th Olympiad. His statues were executed in wood, bronze, and marble, and though not of the highest order of merit, were sufficiently esteemed in their day.

CALLOSA DE ENSARRIA, a town of Spain, on the left bank of the Guadalest, district of Alicante, province of Valencia. It contains about 1000 houses, and is the centre of a fine agricultural district, which is, however, very subject to earthquakes. The principal productions are raisins, pulse, wheat, maize, olives, almonds, and figs. Pop. 4328.

CALLOSA DE SEGURA, a small town near the river Segura, in the district of Alicante, Valencia, Spain, situated on the western slopes of the Sierra Callosa, 27 miles S.W. from Alicante. Its trade is limited to the exportation of the produce of the district, and the importation of manufactured articles for home consumption. Pop. 2904.

CALLOT, JACQUES, an eminent French engraver, was born in 1593 at Nancy in Lorraine, where his father was a herald-at-arms. He early discovered a very strong predilection for art, and at the age of twelve quitted the paternal abode without his father's consent, and set out for Rome, where he intended to prosecute his studies. Being utterly destitute of funds he joined a troop of Bohemians, and arrived in their company at Florence. In this city he had the good fortune to attract the notice of a gentleman of the court who supplied him with the means of study; but he removed in a short time to Rome, where, however, he was recognised by some relatives, who immediately compelled him to return home. Two years after this, and when only fourteen years old, he again left France contrary to the wishes of his friends, and reached Turin before he was overtaken by his elder brother, who had been despatched in quest of him. As his enthusiasm for art remained undiminished after these disappointments, he was at last allowed to accompany the Duke of Lorraine's envoy

to the papal court. His first care was to study the art of design, of which in a short time he became a perfect master. Philip Thomasin instructed him in the use of the graver, which, however, he ultimately abandoned, substituting the point as better adapted for his purposes. From Rome he went to Florence, where he remained till the death of Cosmo II., the Mæcenas of these times. On returning to his native country, he was warmly received by the then Duke of Lorraine, who admired and encouraged him. As his fame was now spread abroad in various countries of Europe, many distinguished persons gave him commissions to execute. By the Infanta Isabella, sovereign of the Low Countries, he was commissioned to engrave a design of the siege of Breda; and at the request of Louis XIII. he designed the siege of Rochelle, and the attack on the Isle of Ré. When, however, in 1631, he was desired by that monarch to execute an engraving of the siege of Nancy, which he had just taken, Callot refused, saying, "I would rather cut off my thumb than do anything against the honour of my prince and of my country;" to which Louis replied—that the Duke of Lorraine was happy in possessing such subjects as Callot.

Shortly after this he returned to his native place, from which the king failed to allure him with the offer of a handsome pension. He died in 1635 at the age of 42. He engraved in all about 1600 pieces, the best of which are those executed in aquafortis. No one ever possessed in a higher degree the talent for grouping a large number of figures in a small space, and of representing with two or three bold strokes the expression, action, and peculiar features of each individual. Freedom, variety, and naïveté characterize all his pieces. His Fairs, his Miseries of War, his Sieges, his Temptation of St Anthony, and his Conversion of St Paul, will be sought after and admired as long as there are artists to learn and a public to appreciate.

CALLY, Pierre, a distinguished French theologian and philosopher, was born at Mesnil Hubert near Argentan, in the department of Orne, about the middle of the seventeenth century. Though destined for the church, he devoted himself at an early age to the study of philosophy, and was the first person in France to adopt in their totality the doctrines of Descartes. The boldness of this step procured for him many enemies, and even interrupted his intercourse with his personal friends, amongst others with Huet, the illustrious bishop of Avranches. When Louis XIV. was organizing the Delphin classics, Cally was appointed to edit the *De Consolatione Philosophiæ* of Boethius. His edition of that work appeared in 1680, and has now become extremely rare. In 1674 he published his *Institutio Philosophica*, which he subsequently enlarged and republished about twenty years after, and in the following year became principal of the college of arts at Caen. In 1684 he became curate of the church of St Martin, and ingratiated himself with the Protestants of that city so successfully, that he converted many of their number. His enemies, however, jealous of his increasing fame, revived against him the old charge of Cartesianism, and procured his banishment. He then settled at Moulins, where he remained for two years. Finding that his popularity with the Protestants of Caen had not been diminished by his absence, he wrote them a letter on the Harmony of Theology with Philosophy, a work which was publicly condemned, apparently with such good reason, that he himself made an open retractation of it, and caused it to be suppressed. Shortly after this event he died in 1709.

CALM Latitudes, or Region of Calms, the tract of the Atlantic Ocean situated between the tropic of Cancer and latitude 29° north.

CALMAR, or Kalmar, a maritime province of Sweden, between N. Lat. 56. 20. and 58. 20. and E. Long. 15. 30. and 17. 0; and bounded east by the Baltic, N.W. by Linköpink, south by Carlskrona, west by Iönkoping and Wexio. Area, including the island of Oeland, 4258 square miles. Pop. (1845) 196,116.

Calmar, or *Kalmar*, the capital of the above province, on Calmar Sound opposite the island of Oeland. N. Lat. 56. 40., E. Long. 16. 20. It is built on the island of Quarnholm, and communicates with the suburbs on the mainland by a bridge of boats. Most of the houses are built of wood; but the cathedral, the castle, the Hôtel-de-Ville, and other public edifices, are of stone, of which there are good quarries in the island of Oeland. It has an academy, and several smaller educational establishments. The harbour is safe and commodious, but a large part of the trade has been transferred to Stockholm. It has manufactories of woollen stuffs, tobacco, and potash; and carries on an export trade in flax, timber, iron, alum, pitch, &c. Calmar was once a flourishing and strongly-fortified town; and gives name to the treaty by which Sweden, Denmark, and Norway were in 1397 erected into one kingdom under Queen Margaret. Pop. about 5500.

CALMET, Augustine, a distinguished scholar and biblical critic, born at Mesnil-la-Horgne in Lorraine, in 1672. In his fifteenth year he went to the university of Pont-a-Mousson, which he attended for a single session. In 1688 he joined the Benedictines at the abbey of St Mansin, into whose order he was publicly received in the following year. His theological and philosophical studies he completed at the abbey of Munster, to which he was sent in 1704 with the rank of sub-prior. He here organized an academy of eight or ten monks, the sole business of whose life was to assist him in preparing his Commentary on the Bible. The publication of this voluminous work, begun in 1707, was not completed till 1716. Two years after this latter date he was rewarded for his services with a presentation to the abbey of St Leopold at Nancy, and ten years after to that of Sénones, where he died in 1757. His attachment to his country and congregation was such, that he refused a bishopric *in partibus* offered to him by the pope, Benedict XIII. Besides his Commentary, he wrote many other works, of which the most important are his *Histoire de l'Ancien et du Nouveau Testament*, an introduction to the Ecclesiastical History of Fleury; *Dictionnaire, historique, critique, et chronologique*, an extremely learned, but by no means judicious work; and *Histoire universelle sacrée et profane*, 15 vols. 4to.

CALNE, a market-town in the hundred of Calne, Wiltshire, 87 miles west from London. It stands in a valley intersected by the little brook of Calne, and is surrounded by the high table-land of Marlborough Downs and Salisbury Plain. The town is clean and well-paved, and contains an ancient church with a tower by Inigo Jones; besides a fine new church in the neighbourhood, and several dissenting chapels. Its educational establishments include a grammar-school, founded in 1660, to which two exhibitions in Queen's College, Oxford, are attached; national and infant schools; and a school for training female servants. It is a vicarage in the archdeaconry of Wilts and diocese of Salisbury. It is also the seat of the county courts, and returns one member to parliament. The municipal borough is governed by a mayor, four aldermen, and twelve councillors. The principal trade of Calne is in corn, although formerly it carried on a considerable manufacture of cloth. Pop. of the municipal borough (1851) 2544; of the parliamentary borough (1851) 5195.

From the remains found in the vicinity, Calne seems to have been an important Roman station. It was the occasional residence of the West Saxon kings; and is celebrated in legendary ecclesiastical history for the miraculous escape of Dunstan at the synod held there in 997.

CALOGERI, or Caloyers, monks of the Greek church, of three orders,—the *archari*, or novices; the ordinary pro-

fessed, or *michrochemi;* and the more perfect, called *megalochemi*. They are also divided into *cœnobites*, who are employed in reciting their offices from midnight to sunrise; *anchorets*, who retire and live in hermitages; and *recluses*, who shut themselves up in grottos and caverns, and subsist by alms furnished to them by the monasteries.

CALOMEL, a preparation of mercury, much used in medicine. See CHEMISTRY.

CALORIC, the principle or matter of heat, or the simple element of heat. See CHEMISTRY, and HEAT.

CALORIMETER, an instrument invented by Lavoisier and Laplace for measuring the heat given out by bodies in cooling, by the quantity of ice they melt.

CALORIMOTOR. See VOLTAIC ELECTRICITY.

CALOTTE, a cap or coif of hair, satin, or other stuff, worn in Popish countries as an ecclesiastical ornament.

CALOTYPE (καλος and τύπος), the name given by Mr H. Fox Talbot to his photogenic process for obtaining copies of natural objects and pictures; in which paper prepared in a particular manner is used, instead of the silvered plates employed for that purpose by M. Daguerre. It is also sometimes called Talbotype, in honour of the inventor. See PHOTOGRAPHY.

CALOVIUS, ABRAHAM, a celebrated Lutheran divine, was born at Mohrungen in Brunswick in 1612. He studied at Rostock and Königsberg, and was professor of theology at Wittemberg when he died in 1686. He took a prominent part in the Socinian and other controversies of the day, but especially distinguished himself in the syncretistic controversy with Calixtus. He carried on his disputes with so great vehemence that his *Historia Syncretistica* was confiscated by the elector of Saxony.

CALPE, a mountain of Andalucia, in Spain, at the foot of which, towards the west, stands the town of Gibraltar. Its extreme length from north to south is 14,700 feet, or a little more than $2\frac{3}{4}$ miles. It is nearly perpendicular on the east and north, and slopes rapidly to the west. Its greatest height is 1450 feet.

CALPURNIUS, TITUS, a Latin Sicilian poet, who lived under the Emperor Carus and his son. Seven of his eclogues are extant.

CALTANISETTA, a province of Sicily, bounded north by the province of Palermo, east by Catania, south by Syracuse and the Mediterranean, west by Girgenti. It is divided into three districts,—viz., Caltanisetta, Piazza, and Terranova,—and has an area of about 1200 square miles, and a population (1851) of 180,791. The soil of the province is somewhat hilly, but well watered and fertile.

CALTANISETTA, the capital of the above province, situated in an extensive and fertile plain near the right bank of the Talso, 62 miles S.E. of Palermo. It is well-built, and contains several handsome edifices. It is defended by a castle, and is the seat of judicial courts. In the neighbourhood, at Terra Pilata, are several springs emitting hydrogen gas, and also extensive sulphur-works. Pop. about 16,000.

CALTROP (the ancient *tribulus*), a small instrument of iron, with four prongs so arranged that when thrown on the ground one of them is always perpendicular. From ancient times this implement has been employed in strategy to impede the progress of cavalry.

CALTURA, a small sea-port town in the district of the same name in Ceylon. It stands on the Kalu Ganga river, about 26 miles south from Colombo, in the centre of a fertile and salubrious district, and is much resorted to by invalids. It was formerly the station of a garrison, and is still the seat of an inferior judicial court. It enjoys a considerable share in the coasting-trade, with Madras and the Eastern ports.

CALUMBA, the root of the *Cocculus palmatus*, a climbing plant resembling bryony, belonging to the Linnean class and order Hexandria Digynia, and to the natural order Menispermaceæ. The root, which is perennial, consists of numerous spindle-shaped tubers which have an intensely bitter taste; and to prepare them for the market they are cut in slices and dried on cords. Calumba is solely used in medicine, and is one of the best pure bitter tonics, being quite free of astringency, and is especially serviceable in dyspepsia, and in affections of the stomach and bowels, often acting as a calmative when irritability exists, as indicated by pain or vomiting after meals.

CALUMET, a symbolical instrument of great importance among the American Indians. The calumet is a pipe made of a soft red marble, and a long reed, ornamented with the wings and feathers of birds. No affair of consequence is transacted without the calumet. It always appears in meetings of commerce or exchanges; in congresses for determining of peace or war; and even in the midst of battle. The acceptance of the calumet is a mark of concurrence with the terms proposed, as the refusal is a mark of rejection. When they treat of war, the pipe and all its ornaments are usually red. The size and decorations of the calumet are for the most part proportioned to the rank of the person to whom it is presented, and to the importance of the occasion. The calumet of war consists of a red stone, like marble, and the tube is a hollow reed. They adorn it with feathers of various colours, and name it the calumet of the sun. From the winged ornaments of the calumet, and its uses, writers compare it to the ancient caduceus, which was carried by the caduceatores, with terms to the hostile states.

CALUMNY, slander, or false accusation made wittingly.

Oath of CALUMNY, *Juramentum*, or rather *Jusjurandum, Calumniæ*, or *de Calumnia*, among civilians and canonists, was an oath which both parties in a cause were obliged to take; the plaintiff that he did not bring his charge, and the defendant that he did not deny it, with a design to abuse the other, but because they believed their cause was just and good; that they would not deny the truth, nor create unnecessary delays, nor offer the judge or evidence any gifts or bribes. If the plaintiff refused this oath, the complaint or libel was dismissed; if the defendent, he was held *pro confesso*. This custom was taken from the ancient athletæ, who, before they engaged, were bound to swear that they had no malice, nor would use any unfair means for overcoming each other. The *juramentum calumniæ* is much disused, as a great occasion of perjury.

CALVADOS, a department in the north of France, extending from 48. 46. to 49. 25. N. Lat., and from 0. 26. E. to 1. 10. W. Long., formed out of that part of Lower Normandy which comprised Bessin, Bocage, the Champagne de Caen, Auge, and the western part of Lieuvin. It received its present name from a ledge of rocks stretching along the coast for a distance of about 15 miles between the mouths of the rivers Orne and Vire, on which the *Calvados*, a vessel belonging to the Spanish Armada, was wrecked in 1588. It is bounded north by the English Channel; east by the department of Eure; south by that of Orne; west by that of Manche; and has an area of 2143 square miles. The southern part of the department is somewhat elevated, being crossed by a mountain range, and forms a continuation of the great water-shed between the basins of the Seine and Loire; but the rest of the surface is gently undulating, and consists of extensive valleys watered by numerous streams which fall into the English Channel. The coast is high, and generally inaccessible except at the mouths of the principal rivers, such as the Touque, the Dive, the Orne, and the Vire, which are navigable at high tide for several miles inland, and are indicated by lighthouses at their mouths. The valleys, which generally slope in a direction from south to north, afford abundant pasturage for horses and cattle, and the agriculture of

the district is superior to that of most of the other departments. Wheat, potatoes, and all kinds of vegetables are raised in great quantities for the markets of the interior and for exportation. The orchards of the Auge district produce a very superior kind of cider, of which upwards of 30,000,000 gallons are made in the department; while Isigny is the centre of a large domestic and export trade in butter, cheese, and other dairy produce. Poultry is reared to a considerable extent for the Paris market. In the larger towns, of which, on account of the agricultural pursuits of the inhabitants there are very few, there are manufactories of lace, (employing upwards of 50,000 persons), woollen yarn and cloth, linen, calicoes, flannel, shawls, cutlery, and earthenware. Besides these the paper-mills, oil-mills, tanneries, refineries of beet-root and foreign sugar, distilleries and bleach-fields scattered throughout the department, give employment to a great number of hands. Although seams of coal are found and wrought at Ligny, most of the coal used in the department is imported from England or Belgium. The fisheries along the coast are extensively prosecuted for Parisian consumpt, and consist chiefly of lobster, oyster, herring, and mackerel fishing. The imports of the department are principally iron, wool, raw cotton, hides, and colonial produce, which form the raw materials for home manufacture. The principal towns are Caen (the capital), Lisieux, Bayeux, Falaise, Honfleur, and Vire, which communicate with each other by excellent roads. The first three stand on the great road from Paris to Cherbourg.

Calvados is divided into six arrondissements, which are peopled and divided as follows: viz.—

Arrondissements.	Cantons.	Communes.	Pop. (1851.)
Caen	9	188	139,922
Falaise	5	121	60,534
Bayeux	6	145	79,976
Vire	6	97	87,075
Lisieux	6	125	67,059
Pont-l'Evêque	5	116	56,644
Total	37	792	491,210

CALVART, Denis, an eminent Flemish painter, born at Antwerp in 1553. After studying for some time in his native city he went to Bologna, where he perfected himself in the anatomy of the human form under Prospero Fontana. From Bologna he went to Rome, where he assisted Sabbatini in his works for the papal palace, and devoted much of his time to copying and studying the works of Raphael. He ultimately returned to Bologna, and founded a school, of which the greatest ornaments are Guido and Domenichino. His works are especially admired for the power of grouping and colouring which they display. He died at Bologna in 1619.

CALVARY, the place where Christ was crucified. In three of the Gospels the Hebrew name Golgotha (*place of a skull*) is given; and in Luke (xxiii. 33), where we find Calvary in the authorized version, the original is not Calvary, but Cranion (κρανίον), a diminutive of κρᾶνον (*a skull*). Calvaria is the Latin translation of this word, adopted by the Vulgate, from which it found its way into our version. For the particulars connected with the site of the Crucifixion, see Jerusalem.

Calvary, a term used in Catholic countries, denotes a chapel of devotion, erected on a hillock near a city, in memory of the place where our Saviour suffered.

Calvary, in *Heraldry*, a cross set upon steps, supposed to resemble the cross of our Saviour.

CALVERT, George, Lord Baltimore, one of the principal secretaries of state under James I., was born at Kipling in Yorkshire in 1582. He retained office for five years, at the end of which term he resigned, alleging as a reason, that he had recently adopted the Catholic faith. He still continued at court, however, in the capacity of a privy-councillor. Among the other rewards he received for his services was a patent as lord of the province of Avalon in Newfoundland. As this colony was much exposed to the attacks of the French he left it, and obtained another patent for Maryland, in the north of Virginia. He died in 1632 before the grant was confirmed, but in that year it was made out in the name of his son Cecil. The city of Baltimore derives its name from the title of this family.

CALVI, a seaport-town of Corsica, on an elevated peninsula in a gulf of the same name. N. Lat. 42. 34. E., Long. 8. 44. Calvi is furnished with a good and well-sheltered harbour, but its trade has greatly decayed, part of it having been transferred to Isola Rossa on the N.E. The citadel is a place of great strength, and under the Genoese, held out for 51 days against the English in 1794. Pop. of the arrondissement of Calvi, 24,390; of the town, 1750.

CALVIN, John, was born at Noyon, in Picardy, on the 10th of July 1509. His father, Gerard Calvin or Cauvin,[1] was a notary-apostolic and procurator-fiscal for the lordship of Noyon, besides holding certain offices in connection with that diocese. The name of his mother was Jeanne Lefranc; she was the daughter of an innkeeper at Cambray, who afterwards came to reside at Noyon. Gerard Cauvin is described as a man of considerable sagacity and prudence, and on this account held in esteem by the leading men of the district. His wife added to considerable personal attractions the graces of a vivid and earnest piety. Their family consisted of four sons, of whom John was the second, and two daughters.

Of Calvin's early years only a few notices remain. His father destined him from the first for theological studies, being moved to this by the evidences afforded in his boyhood of a religious tendency, and perhaps also by a shrewd apprehension of the kind of pursuits in which he was most fitted to excel. The esteem in which the father was held opened for the boy a place in the household of the noble family of De Montmor, where he received his elementary education along with the children of the house, though at his father's expense. In his thirteenth year his father, whose circumstances were not affluent, procured for him from the bishop a benefice in the Chapelle de Notre Dame de la Gesine. In this office he was installed on the 29th of May 1521, and the income thence derived, enabled him to accompany the young De Montmors to Paris, and to prosecute his studies there. His first school was the Collége de la Marche, at that time under the regency of Maturin Cordier, a man of excellent character, of sound learning, and high repute as a teacher. From this institution he removed to the Collége Montaigu, where he had for instructor a Spaniard, who is described as a man of learning, and to whom Calvin was indebted for the culture of his already acute intellect, by the study of dialectics and the scholastic philosophy. Whilst at school the future reformer distinguished himself by his superior abilities, and his indefatigable assiduity. He speedily outstripped all his competitors in grammatical studies, and by his skill and acumen

[1] The family name of Calvin seems to have been written indifferently Cauvin, Chauve, Chauvin, Calvus, Calvinus. In the contemporary notices of Gerard and his family, in the capitular registers of the cathedral at Noyon, the name is always spelt Cauuin. At one time the reformer appeared inclined to adopt Alcuinus as the Latinized form of his name, for in two editions of his *Institutio* this name appears as that of the author (Audin, *Vie de Calvin*, i., 520). The syndics of Geneva address him in a letter written in 1540, and still preserved, as "Docteur Caulvin." In his letters written in French he usually signs himself "Jean Calvin." He affected the title of "Maître," for what reason is not known.

as a student of philosophy, gave fruitful promise of that consummate excellence as a reasoner, in the department of speculative truth, which he afterwards displayed.

In his nineteenth year he, through the influence of his father, obtained the living of Marteville, to which he was presented on the 27th of September 1527. After holding this preferment for nearly two years, he exchanged it in July 1529 for the cure of Pont-l'Evêque, a village near to Noyon, and the place to which his father originally belonged. He appears to have been not a little elated by his early promotion, and although not ordained, he preached several sermons to the people. But though the career of ecclesiastical preferment was thus early opened to him, Calvin was destined not to become a priest of the Church of Rome. A change came over the mind both of his father and himself respecting his future career. Gerard Calvin, looking at things only from a worldly point of view, began to suspect that he had not chosen the most lucrative profession for his son, and that the law offered to a youth of his talents and industry a more promising sphere.[1] His son, on the other hand, had come under an influence of a very different kind, but which, with still more decisive impulse, inclined him to relinquish the ecclesiastical life. Through the counsels of his relation, Pierre Robert Olivetan, the first translator of the Bible into French, he had been led for the first time to study the sacred volume, and to test his religious opinions and practices by its dictates. The result was that, though not yet detached from the faith of the Romish church, he was very willing to relinquish all thoughts of becoming a priest in that communion. He accordingly readily complied with his father's suggestion, and having resigned his benefice, removed from Paris to Orleans, in order to study law under Pierre de l'Etoile, a distinguished jurisconsult, and at that time professor there. On this new pursuit Calvin entered with characteristic ardour, and such was his progress in legal knowledge, that he frequently occupied the chair of the professor, while his general reputation for ability and scholarship stood so high, that on leaving Orleans, he received the grade of doctor without payment of the usual fees, as a compliment to his merits. Other studies, however, besides those of law had occupied him whilst in this city. God, who had destined him for a very different career, was in his providence preparing him for the work he had to do. His mind, at first hardened by the influence of early superstition, was, he himself tells us, brought by a sudden conversion into a state of docility.[2] An ardent desire to attain proficiency in sound knowledge took possession of him, and though this did not lead him to renounce other studies, it rendered him frigid in the pursuit of them. At all times, indeed, a diligent student, he seems at this time to have been impelled by his zeal beyond those bounds which a wise regard to health would impose. It was his wont, after a frugal supper, to labour till midnight, and in the morning when he awoke, he would, before he arose, recal and digest what he had read the previous day, so as to make it thoroughly his own. "By these protracted vigils," says Beza, "he secured indeed a solid erudition, and an excellent memory; but it is probable he at the same time sowed the seeds of that disease which occasioned him various illnesses in after life, and at last brought upon him premature death."[3]

From Orleans Calvin went to Bourges to prosecute his studies under a learned Italian of the name of Alciati, whom Francis I. had invited into France, and settled as a professor of law in that university. Here he became acquainted with Melchior Volmar, a German, then professor of Greek at Bourges, and a man of sound erudition as well as exemplary character. By him Calvin was taught Greek, and introduced to the study of the New Testament in its original language, a service which he gratefully acknowledges in one of his printed works.[4] The conversation of Volmar also seems to have been of use to him in deepening his religious convictions, and confirming him in his attachment to the doctrines of the Reformation. These were now beginning to be widely diffused through France. Twelve years had elapsed since Luther had published his theses against Indulgences; twelve years of intense excitement and anxious discussion, not in Germany only, but in almost all the adjacent kingdoms. In France there had not been as yet any overt revolt against the Church of Rome, but multitudes were lending a friendly ear to the reformed doctrines, and a few were in secret rejoicing in having heartily embraced them. To such Calvin united himself whilst at Orleans, and after his removal to Bourges he became a teacher, both in private conference with inquirers and by discourses in more public assemblies. "Before a year had elapsed," says he, speaking of his conversion, "all who were desirous of a purer doctrine were in the habit of coming to me, though a novice and a tyro, for the purpose of learning."[5] And Beza tells us, that he not only fortified the few believers who were in the town, but preached often in some of the neighbouring mansions and hamlets, whereby he wonderfully advanced the kingdom of God in many families, among which he specifies that of the lord of Lignières, who with his lady heard with approval the new doctrines.[6] In engaging in such efforts, Calvin appears to have yielded to a constraining sense of duty rather than to have followed the bias of his own inclinations. "By nature," says he, "somewhat clownish (*subrusticus*), I always preferred the shade and ease, and would have sought some hiding place; but this was not permitted, for all my retreats became like public schools."[7] Nor did he infuse any of the enthusiasm which usually marks the young reformer into his addresses. "He taught the truth," says Beza, "not with affected eloquence; but with such depth of knowledge, and so much solid gravity of style, that there was not a man who could hear him without being ravished with admiration."[8]

His residence at Bourges was cut short by the sudden death of his father, which occasioned his return to his native place. Immediately after his father's decease, he seems to have paid a hasty visit to Paris, and then to have returned to Noyon, where he resided for a couple of years or so. At the close of this period he appears to have taken up his abode permanently in the capital. Here he associated with the friends of evangelical truth, and frequented their assemblies, where he frequently preached. To the great joy of all such, he at length relinquished his legal pursuits, and devoted himself afresh to theology. He now gave himself up wholly to the work of the Lord, preaching with great energy, and using all the means in his power to win converts to the truth, as well as to confirm those by whom it had been already embraced. By this time the Reformation had attracted so many adherents in France, that the upholders of the established system became infuriated, and attempted to stay its further progress by the most cruel persecutions. In the hope of working upon the better feelings of those in power, and especially of the king, who was known to be favourable to literature, Calvin published an edition of Seneca's book *De Clementia*, accompanied by a commentary, in which he not only illustrates his author, but gives utterance to sentiments evidently intended to bear upon the conduct of the king in suffering his subjects to be tortured and burnt for their religious opinions. This book he published at his own cost, and dedicated to Claude Hangest, abbot of St Eloi, a member

of the De Montmor family, with whom Calvin had been brought up. The commentary displays extensive acquaintance with ancient literature, though the author has fallen into the ridiculous mistake of running the two Senecas, father and son, into one, and making the philosopher die 115 years old.

This work was published in April 1532. Calvin was now in his 24th year, and was already recognised as at the head of the Reformation movement in France. An occasion soon occurred which brought him into open collision with the dominant party. Nicholas Cop, the newly elected regent of the Sorbonne, had to deliver an oration according to custom in the Church of the Maturins, on the feast of All Saints. Being intimate with Calvin, he pronounced an oration which the latter had prepared for him, "of a totally different sort," says Beza, "from what was customary."[1] It was in fact a defence of the reformed opinions, especially of the doctrine of justification by faith alone. This was more than the Sorbonnists could bear, and Cop being summoned to appear before the parliament, found it necessary to make his escape from Paris to Basle. An attempt was at the same time made to seize Calvin, but being forewarned of the design by his friends, he also made his escape. His lodgings, however, were searched, and his books and papers seized, to the imminent peril of some of his friends, whose letters were found in his repositories. He himself took refuge at the court of the queen of Navarre, the only sister of Francis I., who then favoured the reformed party, and through whose intercession the storm which had broken out against them at this time was quieted. Calvin after this retired to Saintonge, where, at the request of a friend, he prepared some short discourses, which were circulated in the surrounding parishes, and read in public to the people. He subsequently removed to Nerac, the residence of the queen of Navarre, where he became acquainted with the venerable Jacques Lefevre d'Estaples, a scholar and man of science, whom the queen had rescued from the fury of the Sorbonnists, and engaged as tutor to her children. By him Calvin was warmly received, and his future eminence as a reformer of the church predicted.

It is believed that it was whilst resident at Saintonge that Calvin prepared the first sketch of his *Institutio Christianæ Religionis*. But his residence in that retirement continued only for a very few months, for in 1534 we find him again in Paris. Here he was compelled to remain concealed, in consequence of the measures which the enemies of the gospel were still pursuing against its adherents. At the risk of his life, however, he came forth to meet one whom he was afterwards to encounter under very different circumstances, the Spanish physician, Servede or Servetus, who was even then engaged in propagating his heretical notions concerning the Trinity. Him, vaunting his desire for a conference, Calvin challenged; but though time and place were fixed, Servetus failed to fulfil his boast. Calvin's design in proposing this colloquy seems to have been a kindly one towards Servetus. "Not without danger to my life," he himself says, "I offered to deliver him from his errors; and it would not have been my fault, had he manifested repentance, if all pious men had not given him their hands."[2] Nor was Servetus the only errorist whom Calvin endeavoured at this time to confute. The Anabaptists of Germany had spread into France, and were disseminating many wild and fanatical opinions among those who had seceded from the Church of Rome. Among other notions which they had imbibed, was that of a sleep of the soul after death. To Calvin this notion appeared so pernicious, that he composed and published a treatise in refutation of it, under the title of *Psychopannychia*. In this work he chiefly dwells upon the evidence from Scripture in favour of the belief that the soul retains its intelligent consciousness after its separation from the body; passing by questions of philosophical speculation, as tending on such a subject only to minister to an idle curiosity.

The *Psychopannychia* was published in 1534 at Orleans, whither Calvin had been constrained, in consequence of the violence of the persecution at Paris, to retreat. He soon after found it necessary to leave France entirely, and with this view set out with his friend Louis Fillet for Basle. On their way they were robbed by one of their servants, who so entirely stripped them of their property, that it was only by borrowing ten crowns from their other servant that they were enabled to get to Strasburg, and thence to Basle. Here Calvin was welcomed by the band of scholars and theologians who had conspired to make that city the Athens of Switzerland, and especially by the learned Simon Grynæus, and by Wolfgang Capito, the leader of the Reformation at Basle. Under the auspices and guidance of the latter, Calvin applied himself to the study of Hebrew.

Francis I., desirous to continue the persecution of the Protestants, but anxious at the same time not to break with the Protestant princes of Germany, resorted to the unworthy expedient of instructing his ambassador to assure the latter that it was only against the Anabaptists, and other parties who called in question all civil magistracy, that his severities were exercised. Calvin, indignant at the calumny which was thus cast upon the reformed party in France, hastily prepared for the press his Institutes of the Christian Religion, which he published as a confession of the reformed faith, and dedicated to the king. Of this edition, which appeared in 1535, no copy is known to be extant. It is described by the author as a mere outline of what afterwards appeared under the same title, and he says he published it anonymously, having in view nothing beyond furnishing a statement of the faith of the persecuted Protestants, whom he saw cruelly cut to pieces by impious and perfidious court parasites.[3] It is supposed to have been written in French. In the year following the work was republished in an enlarged form in Latin, and with the author's name.[4] In this work, though produced when the author was only twenty-five years of age, we find a full development of that theological system which has since borne his name. In none of the later editions, nor in any of his later works, do we find reason to believe that he ever changed his views on any essential point from what they were at the period of its first publication. Such an instance of maturity of mind and of opinion at so early an age, would be remarkable under any circumstances; but in Calvin's case it is rendered peculiarly so, by the shortness of the time which had elapsed since he gave himself to theological studies. It may be doubted also if the history of literature presents us with another instance of a book written at so early an age, which has exercised such a prodigious influence upon the opinions and practices both of contemporaries and of posterity.

After a short visit to the court of the Duchess of Ferrara, which at that time afforded an asylum to several learned and pious fugitives from persecution, Calvin returned to France to arrange his affairs before finally taking farewell of his native country. His intention was to settle at Basle, and to devote himself to study. But being unable, in consequence of the disturbed state of the country, to reach Basle by the ordinary route, he had to take the route through Geneva. Whilst in this city his further progress was arrested, and his resolution to pursue the quiet path of studious research was dispelled, by what he calls the "formidable ob-

[4] This edition forms a small 8vo of 514 pages, and 6 pages of index. It appeared at Basle from the press of Thomas Platter and Balthasar Lasius in March 1536.

testation" of Farel.[1] After many struggles and no small suffering, this energetic spirit had succeeded in planting the evangelical standard at Geneva; and anxious to secure the aid of such a man as Calvin, he entreated him on his arrival to relinquish his design of going farther, and to devote himself to the work in that city. Calvin at first declined, alleging as an excuse his need of securing some more time for personal improvement than could be obtained were he engaged in ministerial work. To the ardent Farel this seemed a mere pretext for indolence. "I tell you," he continued, "in answer to this pretence of your studies, in the name of Almighty God, that if you will not devote yourself with us to this work of the Lord, the Lord will curse you as one seeking not Christ so much as himself." Startled by this denunciation, and feeling as if God had laid his hand on him to detain him, Calvin consented to remain at Geneva, where he was immediately appointed teacher of theology. He was also elected preacher by the magistrates with the consent of the people, but this office he would not accept until it had been repeatedly pressed upon him. His services seem to have been rendered for some time gratuitously, for in February 1537 there is an entry in the city registers to the effect that six crowns had been voted to him, "since he has as yet hardly received anything."

Calvin was in his twenty-eighth year when he was thus providentially arrested at Geneva; and in this city the rest of his life, with the exception of a brief interval, was spent. The post to which he was thus called was not an easy one. Though the people of Geneva had cast off the yoke of Rome, they were still "but very imperfectly enlightened in divine knowledge; they had as yet hardly emerged from the filth of the papacy."[2] This laid them open to the incursions of those fanatical teachers, whom the excitement attendant upon the Reformation had called forth, and who hung mischievously upon the rear of the reforming body. To obviate the evils thence resulting, Calvin, in union with Farel, drew up a condensed statement of Christian doctrine, and prepared an elementary catechism to accompany it. These the citizens were summoned, in parties of ten each, to profess and swear to as the confession of their faith—a process which, though not in accordance with modern notions of the best way of establishing men in the faith, was gone through, Calvin tells us, "with much satisfaction." As the people took this oath in the capacity of *citizens*, we may see here the basis laid for that theocratic system which subsequently became peculiarly characteristic of the Genevan polity. Of the troubles which arose from fanatical teachers, the chief proceeded from the efforts of the Anabaptists; but these Calvin and his colleagues so effectually silenced by means of a public disputation held on the 18th of March 1537, that they never afterwards appeared at Geneva. In the course of this year also, the peace of Calvin and his friends was much disturbed, and their work interrupted, by a turbulent and unprincipled preacher named Peter Caroli, who, after many changes of religious profession (with none of which, however, had he associated anything of true religion, or even much of ordinary morality), had assumed the character of a stickler for orthodoxy. In this character he accused the Geneva divines of Sabellianism and Arianism, because they would not enforce the Athanasian creed, and had not used the words *Trinity* and *Person* in the confession they had drawn up. In a synod held at Berne the matter was fully discussed, when a verdict was given in favour of the Geneva divines, and Caroli deposed from his office and banished. Thus ended an affair which seems to have occasioned Calvin much more uneasiness than the character of his assailant, and the manifest falsehood of the charge brought against him, would seem to justify. Two brief tracts, intended to expose the evils and warn against the seductions of Popery, one entitled *De Fugienda Idolatria*, the other *De Papisticis Sacerdotiis*, must be added to the labours of Calvin this year.

Hardly was the affair of Caroli settled, when new and severer trials came upon the Genevan Reformers. The severe simplicity of the ritual which Farel had introduced, and to which Calvin had conformed; the strictness with which the ministers sought to enforce not only the laws of morality, but certain sumptuary regulations respecting the dress and mode of living of the citizens; and their determination in spiritual matters not to submit to the least dictation from the civil power, led to such violent dissensions that Calvin and his colleagues refused to administer the sacrament to the people. For this they were banished from the city. They went first to Berne, and soon after to Zürich, where a synod of the Swiss pastors had been convened. Before this assembly they pleaded their cause and stated what were the points on which they were prepared to insist as needful for the proper discipline of the church. They declared that they would yield in the matter of ceremonies so far as to employ unleavened bread in the eucharist, to use fonts in baptism, and to allow festival days, provided the people might pursue their ordinary avocations after public service. These Calvin regarded as matters of indifference, provided the magistrates did not make them of importance, by seeking to enforce them; and he was the more willing to concede them, because he hoped thereby to meet the wishes of the Bernese brethren, whose ritual was less simple than that established by Farel at Geneva. But he and his colleagues insisted, on the other hand, that for the proper maintenance of discipline, there should be a division of parishes—that excommunications should be permitted, and should be under the power of elders chosen by the council, in conjunction with the clergy—that order should be observed in the admission of preachers—and that only the clergy should officiate in ordination by the laying on of hands. It was proposed also, as conducive to the welfare of the church, that the sacrament of the Lord's Supper should be administered more frequently, at least once every month, and that congregational singing of psalms should be practised in the churches. On these terms the synod interceded with the Genevese to restore their pastors; but through the opposition of the Bernese this was frustrated, and a second edict of banishment was the only response.

Calvin and Farel betook themselves, under these circumstances, to Basle, where they soon after separated, Farel to go to Neufchatel, and Calvin to Strasburg. At the latter place Calvin resided till the autumn of 1541, occupying himself partly in literary exertions, partly as a preacher in the French church, and partly as a lecturer on theology. In 1539 he attended the convention at Frankfort as the companion of Bucer, and in the following year he appeared at that at Hagenau and Worms, as the delegate from the city of Strasburg. He was present also at the diet at Ratisbon, where he became personally acquainted with Melanchthon, and formed with him a friendship which lasted through life. It is to this period of his life that we owe the completed form of his *Institutio*, his commentary on the Epistle to the Romans, and his tract on the Lord's Supper. Notwithstanding his manifold engagements, he found time to attend to the tenderer affections; for it was during his residence at Strasburg that he married Idelette de Bures, the widow of a person named Stórder, whom he had converted from Anabaptism.

During his absence, disorder and irreligion had prevailed in Geneva. An attempt was made by Sadolet, Bishop of Carpentras, to take advantage of this so as to restore the papal supremacy in that district; but this design Calvin, watchful over the interests of his ungrate-

[2] Beza, *Vit. Calv. an.* 1536.

ful flock, though exiled from them, completely frustrated by writing such a reply to the letter which the bishop had addressed to the Genevese, as constrained him to desist from all further efforts. He seems also to have kept up his connection with Geneva by addressing letters of counsel and comfort to the faithful there who continued to regard him with affection. It was whilst he was still at Strasburg that there appeared at Geneva a translation of the Bible into French, bearing Calvin's name, but in reality only revised and corrected by him from the version of Olivetan. Meanwhile providence was opening the way for his return to the post whence he had been driven in that city. In the summer of 1541, the decree of his banishment was reversed, and in the following September he yielded to the earnest entreaties of his now penitent flock, and returned to Geneva, where he was received with the utmost enthusiasm. He entered upon his work with a firm determination to carry out those reforms which he had originally purposed, and to set up in all its integrity that form of church policy which he had carefully matured during his residence at Strasburg. He now became the sole directive spirit in the church at Geneva. Farel was retained by Neufchatelois, and Viret soon after Calvin's return removed to Lausanne. His duties were thus rendered exceedingly onerous, and his labour became excessive. Besides preaching every day in each alternate week, he taught theology three days in the week, attended weekly meetings of his consistory, read the Scriptures once a-week in the congregation, carried on an extensive correspondence on a multiplicity of subjects, prepared commentaries on the books of Scripture, and was engaged repeatedly in controversy with the opponents of his opinions. "I have not time," he writes to a friend, "to look out of my house at the blessed sun, and if things continue thus, I shall forget what sort of appearance it has. When I have settled my usual business, I have so many letters to write, so many questions to answer, that many a night is spent without any offering of sleep being brought to nature." We cannot in this sketch follow him through all the details of his brief but busy life after he returned to Geneva; we can only afford to notice slightly the leading events.

Of the controversies in which Calvin embarked, one of the most important was that in which he defended his doctrine concerning predestination and election. His first antagonist on this head was Pighius, a Romanist, who, resuming the controversy between Erasmus and Luther on the Freedom of the Will, violently attacked Calvin for the views he had expressed on that subject. Calvin replied to him in a work published in 1543, in which he defends his own opinions at length, as well by general reasonings as by an appeal to both Scripture and the Fathers, especially Augustine. So potent were his reasonings in the esteem of his opponent, that the latter, though owing nothing to the gentleness or courtesy of Calvin, was led to embrace his views. A still more vexatious and protracted controversy on the same subject arose in 1551, in which Calvin was called to defend his views against Bolsec, a Protestant physician, resident at Geneva, and in which ultimately several others, including Castellio, Fabri, and even Bullinger and Melanchthon, took part against him, and only Beza appeared as a zealous coadjutor. But the most memorable of all the controversies in which Calvin was engaged, was that into which he was brought in 1553, with his old antagonist Servetus. After many wanderings, and after having been condemned to death for heresy at Vienne, from which he was fortunate enough to make his escape, this restless adventurer arrived in June 1553 at Geneva. He appears to have remained in quiet here for a month, and was about to leave it for Zürich when he was arrested and conveyed to prison on the charge of blasphemy. He had long been looked upon with dislike by the Reformers, not only as a teacher of doctrines repugnant to all their convictions of truth, but as a mischievous disturber of the peace of the churches and an enemy of the good. At Geneva Calvin appeared as his accuser, and the conflict was conducted between the two with much ability on both sides, and at the same time with much rancour and scurrility, especially on the part of Servetus. After a protracted trial, the accused was condemned to be burnt to death. For so severe a sentence Calvin does not seem to have been prepared. He had engaged in the prosecution at first in the earnest hope that Servetus might be led to see the error of his opinions, and recal at least some of his blasphemous speeches; and though, on finding that all his efforts at confutation were not only thrown away upon the accused, but tended to make him only the more furious and blasphemous, he—in accordance with the common belief of the age, and with the approval of all his contemporaries among the Reformers—gave his suffrage for his being punished with death, he yet wished that what was horrible in the punishment might be spared, and made efforts to induce the senate to inflict a milder death than that by fire. These, however, proved in vain, and Servetus was accordingly burned at Champel near Geneva, on the 27th of October 1553. Farel attended him in his last hours and accompanied him to the place of execution. He had an interview also with Calvin on the morning of the fatal day, when he asked his forgiveness, but refused to retract any of his expressions. Calvin has been much censured, not to say vituperated, for his share in this unhappy transaction; but he was not more to blame than were the rest of the Reformers, all of whom approved of the prosecution, and concurred in the equity of the sentence as far as Calvin did; and, in judging of them in this matter, we must bear in mind that the unanimous opinion of their age pronounced death to be the proper penalty of blasphemy—the offence for which Servetus was condemned. According to modern opinions such a sentence was detestable; but when it is remembered that only a few years have passed since, in the most enlightened countries of Christendom, it was deemed proper to inflict capital punishment for such offences as forgery or robbery to a small amount, it will not perhaps appear so surprising that pious and earnest men, three centuries ago, should have thought it right to deal in the same way with an offence greatly more wicked in itself, and more injurious to society, than any act of dishonesty however great.

The heresy of Servetus was not extirpated by his death, but as it was his gross and insulting blasphemies, and not his heretical opinions, for which he had been doomed to suffer the last penalty of the law, none of his followers were visited with severer penalties than that of banishment from Geneva. The trials of several of these, with the conferences and controversies connected with them, occupied much of Calvin's time for several years. He was also involved in a protracted and somewhat vexing dispute with the Lutherans respecting the Lord's Supper, which ended in the separation of the evangelical party into the two great sections of Lutherans and Reformed; the former of whom hold that in the eucharist the body and blood of Christ are substantially present, and so are actually partaken of by the communicants, whilst the latter maintain that there is only a virtual presence of the body and blood of Christ, and consequently only a spiritual participation thereof through faith. In connection with these controversies on points of faith, Calvin was for many years greatly disquieted and sometimes even endangered by the opposition offered by the libertine party in Geneva to the ecclesiastical discipline which he had established there. His system of church polity was essentially theocratic; it assumed that every member of the state was also under the discipline of the church; and he asserted that the right of exercising this discipline was vested exclusively in the consistory or body of preachers and elders. His attempt to carry out these views brought him into collision both with the authorities and with the mob; the

latter being enraged at the restraints imposed upon the disorderly by the exercise of church discipline, and the former being inclined to retain in their own hands a portion of that power in things spiritual which Calvin was bent on placing exclusively in the hands of the church rulers. His dauntless courage, his perseverance, and his earnestness at length prevailed, and he had the satisfaction, before he died, of seeing his favourite system of polity firmly established, not only at Geneva, but in other parts of Switzerland, and of knowing that it had been adopted substantially by the Reformers in France and Scotland.

Amidst these multitudinous cares and occupations, Calvin found time to commit to writing a number of works besides those provoked by the various controversies in which he was engaged. The most important and numerous of these were of an exegetical character. Including discourses taken down from his lips by faithful auditors, we have from him expository comments or homilies on nearly the whole of the books of Scripture, written partly in Latin and partly in French. In the estimation of many, these constitute the most valuable of his works. His candour and sincerity as an inquirer into the meaning of Scripture —his judiciousness, penetration, and tact in eliciting his author's meaning—his precision, condensation, and concinnity as an expositor—the accuracy of his learning, the closeness of his reasoning, and the elegance of his style, all conspire to confer a high value on his exegetical works, and to make them at once rich sources of biblical knowledge and admirable models of biblical exposition.

Labours so incessant and so exhausting could not but tell on the strongest constitution: how much more on one so fragile as that of Calvin! Amid many sufferings, however, and frequent attacks of sickness, he manfully pursued his course for twenty-eight years; nor was it till his frail body, torn by many and painful diseases—fever, asthma, stone, and gout, the fruits for the most part of his sedentary habits and unpausing activity—had, as it were, fallen to pieces around him, that his indomitable spirit relinquished the conflict. In the early part of the year 1564 his sufferings became so severe that it was manifest his earthly career was rapidly drawing to a close. On the 6th of February of that year he preached his last sermon, having with great difficulty found breath enough to carry him through it. He was several times after this carried to church, but never again was able to take any part in the service. With a noble disinterestedness, he refused to receive his stipend, now that he was no longer able to discharge the duties of his office. In the midst of his sufferings, however, his zeal and energy kept him in continual occupation: when expostulated with for such unseasonable toil, he replied, "Would you that the Lord should find me idle when he comes?" After he had retired from public labours he lingered for some months, enduring the severest agony without a murmur, and cheerfully attending to all the duties of a private kind which his diseases left him strength to discharge. A deep impression seems to have been made on all who visited him on his deathbed; they saw in him the noble spectacle of a great spirit that had done its life-work, calmly and trustfully passing through the gate of suffering into the long-desired and firmly-expected repose of heaven. He quietly expired in the arms of his faithful friend Beza, on the evening of the 27th of May, in the fifty-fifth year of his age.

Calvin was of middle stature; his complexion was somewhat pallid and dark; his eyes, to the latest clear and lustrous, bespoke the acumen of his genius. He was sparing in his food and simple in his dress; he took but little sleep, and was capable of extraordinary efforts of intellectual toil. His memory was prodigious, but he used it only as the servant of his higher faculties. As a reasoner he has seldom been equalled, and the soundness and penetration of his judgment were such as to give to his conclusions in practical questions almost the appearance of predictions, and inspire in all his friends the utmost confidence in the wisdom of his counsels. As a theologian, he stands on an eminence which only Augustine has surpassed; whilst in his skill as an expositor of Scripture, and his terse and elegant style, he possessed advantages to which Augustine was a stranger. His private character was in harmony with his public reputation and position. If somewhat severe and irritable, he was at the same time scrupulously just, truthful, and steadfast; he never deserted a friend or took an unfair advantage of an antagonist; and on befitting occasions could be cheerful and even facetious among his intimates. "I have been a witness of him for sixteen years," says Beza, "and I think I am fully entitled to say that in this man there was exhibited to all an example of the life and death of the Christian, such as it will not be easy to depreciate, such as it will be difficult to emulate." [1] (W. L. A.)

CALVINISM, the doctrine and sentiments of Calvin and his followers. See THEOLOGY.

CALVISIUS, SETHUS, a German astronomer and chronologer, born at Groschleben in Thuringia in 1556. He studied at Helmstadt, where he made great progress in classical literature as well as in the sciences, in which he afterwards became so distinguished. He was offered a professorship of mathematics at Frankfort, and afterwards at Wittemberg, both of which he declined. He agreed, however, to conduct the school of music, established at Pforte; an office which he afterwards exchanged for a similar situation at Leipzig. At Frankfort he published, in 1585, his *Opus Chronologicum*, a work compiled on astronomical principles. He likewise organized a system of chronology, embodying the history of the world, upon an ingenious and original plan, highly commended by Casaubon and Scaliger. This work, though strongly condemned in the *Index Expurgatorius*, has been frequently reprinted. In 1612, Calvisius published his *Elenchus Calendarii Gregoriani, et duplex Calendarii melioris forma*, in which he attempts to prove the inadequacy of the Gregorian calendar, and proposes to introduce a new system based upon astronomical principles. The only proof now extant of his musical knowledge is his treatise entitled *Melodiæ condendæ ratio.* He died at Leipzig in 1617.

CALVUS, CAIUS LICINIUS, a Roman orator and poet, born B.C. 82. At a very early age he devoted himself to study with such intensity, that his constitution was prematurely broken, and he died before proper means had been taken for transmitting his various works to posterity. As an orator, he is generally classed with Cæsar and Pollio, and has sometimes been compared with Cicero himself. What he really was as an orator cannot now be ascertained, as of the 21 orations which he left behind him at his death only the titles and some small fragments of five have been preserved. One of these against Vatimius is said by Seneca to have produced so strong an effect upon the accused, that before the orator had finished his speech he cried out, "I ask you, judges, if I am to be condemned because my accuser is eloquent?" As a poet he took rank with Catullus, and distinguished himself by his elegies, his epigrams directed against Cæsar and Pompey, and his fugitive pieces of wit and humour. These, unfortunately, have all shared the fate of his orations. The year of his death is unknown;

[1] *Vit. Calv. sub. fin.* This is the principal source for the facts of Calvin's life. Beza's narrative has been expanded and illustrated from other sources by Dr Henry in his *Leben Calvins*, of which an English translation has appeared in 2 vols. 8vo, by the Rev. H. Stebbing. Audin has written a life of Calvin in French full of misrepresentations and blunders. A highly respectable work has recently appeared on the same subject from the pen of Mr Dyer in 1 vol. 8vo.

but we gather from Cicero, that he had not completed his thirty-sixth year.

CALX properly signifies lime; but among chemists it is used to denote the friable mass or powder which remains after a metal or mineral has been subjected to the process of calcination, solution by acid, or detonation by nitre. Metallic calxes are now termed oxides. See CHEMISTRY.

CALYCISTÆ, the name given by Linnæus to those botanists who have arranged all vegetables from the different species, structure, &c. of the calyx or flower-cup. The only systems of this kind are the *Character Plantarum Novus*, by Magpolius, published in 1720; and Linnæus's *Methodus Calycina*, published in his *Classes Plantarum*, at Leyden, in 1738.

CALYDON, in *Ancient Geography*, a town of Ætolia, situated seven miles and a half from the sea, and divided by the river Evenus. It is said to have been founded by Calydon, the son of Ætolus, and was the scene of the famous hunt of the Calydonian boar.

CALYPSO, in Grecian fable, was a daughter of Oceanus and Tethys, or of Nereus, or of Atlas, and reigned in the mythical island of Ogygia. When Ulysses was shipwrecked on her shores, Calypso entertained the hero with great hospitality; and by the united influence of her love and spells, she prevailed on him to remain and share her honours. In this manner seven years had elapsed, when Ulysses was seized with an irresistible desire to revisit his native country. Calypso tried every expedient, and even the promise of eternal youth, to induce the hero to remain; and when all her efforts had proved unavailing and he set sail, grief at his departure occasioned her death. (Hesiod, *Theog.* 359; Hom. *Od.* i. 50, v. 28, vii. 254; Apollod. i. 2, § 7.)

CALYX (κάλυξ, a cup), the outer covering of a flower, or that part which in most plants surrounds and supports the bottom of the corolla. See BOTANY.

CAM, a contrivance of several kinds for converting a rotatory into a reciprocating motion. See MECHANICS.

CAMAIEU, or CAMEO, a peculiar kind of onyx; also a stone, on which are found various figures or representations of landscapes, a kind of *lusus naturæ*, exhibiting pictures without painting. It is of these *camaieux* that Pliny is understood to speak when he says of the manifold pictures of gems, and the particoloured spots of precious stones, *Gemmarum pictura tam multiplex lapidumque tam discolores maculæ.*

CAMEO is also frequently applied to any kind of gem on which figures are sculptured, either indentedly or in relievo. The shell of large univalves is now much used for making cameos; the subject being wrought on the outer or white layer of the shell, and the pink or brown under one serving for the ground.

CAMEO is also used for a painting of only one colour, where the lights and shadows are of gold, wrought on a golden or azure ground. When the ground is yellow the French call it *cirage;* when gray, *grissaile.* This kind of work is chiefly used to represent basso relievos. The Greeks called such works μονοχρωματα.

CAMALDULIANS, CAMALDUNIANS, or CAMALDOLITES, an order of religious persons, founded by Romuald, an Italian, in 1023, in the desolate waste of Camaldoli, or Campo Malduli, on the lofty heights of the Apennines. Their rule is that of St Benedict; and their houses, by the statutes, can never be less than five leagues from cities. They are divided into cœnobites and eremites. The *Camaldulians*, till the close of the eleventh century, were called *Romualdins:* previously, *Camaldulian* was a particular name for those of the desert Camaldoli. Guido Grandi, a Camaldulian monk, and mathematician to the grand duke of Tuscany, published *Camaldulian Dissertations* on the origin and establishment of this order

CAMALODUNUM, the capital of the Trinobantes, the first Roman colony in Britain. From the Itineraries it appears to have stood where Malden now stands; but according to some it occupied the site of the modern Colchester. It continued to be an open town under the Romans, a place of pleasure rather than strength. It was adorned with a Roman theatre and a temple, the building of which the Britons considered as badges of slavery, and resented by several seditions and commotions.

CAMANDOO, a town of Hindustan, in the territory of the Sikhs, province of Lahore, situated on the east side of the Beyah river, 124 miles N.E. from the city of Lahore. E. Long. 75. 50., N. Lat. 32. 26.

CAMARGUE, an island formed by the alluvial soil deposited at the mouth of the Rhone. See BOUCHES-DU-RHÔNE.

CAMARINA, a Syracusan colonial town in the south of Sicily, near the sea, founded about 600 B.C. The ruins are now insignificant; but it was once a place of note, and fine silver coins of this city are extant in the British Museum and other collections.

CAMASSEI, ANDREA, a celebrated historical and landscape painter and engraver, born in 1602, at Bevagna, near Foligno. He studied at Rome under Domenichino and Andrea Sacchi. His principal works are to be seen in the Pantheon, the church of the Capuchins, and the Baptistery of St John Lateran. They are remarkable for sweetness of colouring, elegance of design, and delicacy of execution. He was also the author of a fine engraving of the Holy Family. Camassei died at Rome in 1648.

CAMBAY, a town of Hindustan, in the province of Guzerat, situated on the river Myhee, at the upper part of the Gulf of Cambay, and supposed to be the Camanes of Ptolemy. It was formerly a very flourishing city, the seat of an extensive trade and celebrated for its manufactures of silk, chintz, and gold stuffs; but its commerce has long since fallen away, and the town has become poor and dilapidated. Among the causes assigned for its decay is the gradually increasing difficulty of access to the town by water. The tides rise upwards of thirty feet, and at high water ships anchor near the town, but at low water the river seems almost dry, yet with so rapid a current, that if a vessel take the ground it must inevitably overset. The trade has in consequence decreased, and is now chiefly confined to the export of cotton. The town is celebrated for its agates and carnelians, which are there cut and polished, and wrought into a great variety of trinkets. The chief demand for these ornaments is from China. The houses in many instances are built of stone, a circumstance indicating the former wealth and grandeur of the city, as the quarries from which the material was hewn are situate at a very considerable distance. A brick wall, three miles in circumference, surrounds the town, inclosing four large reservoirs of good water, and three bazaars. To the S.E. of the town there are very extensive ruins of subterranean temples and other buildings half buried in the sand, with which the ancient town was overwhelmed. These temples belong to the Jains, and contained two massive statues of their deities, the one black, the other white. The principal one, as the inscription intimates, is Pariswanath, or Parswanatha, carved and consecrated in the reign of the Emperor Akbar; the black one has the date of 1651 inscribed. It is supposed that Cambay about the fifth century was the capital of the Hindu emperors of Western India; and Osorio, a Portuguese writer of the sixteenth century, says, that when Francis D'Almeida landed near Cambay, he saw the ruins of sumptuous buildings and temples, which seemed to be the remains of an ancient city. In 1780 it was taken possession of by the army of General Goddard, and restored to the Mahrattas in 1783, who imposed on the Nawaub a tribute of L.6000 per annum, and was afterwards ceded to the British by the Peishwa under the treaty of 1803. The military esta-

blishment of the Nawaub consists of 1700 horse and foot, who are employed indiscriminately in revenue, police, and miscellaneous duties. A few pieces of ordnance complete the military resources of the chief. Cambay is distant north from Bombay 230 miles. N. Lat. 22. 18., E. Long. 72. 39.

The Gulf of Cambay, which is shallow, and abounds in shoals and sand-banks, penetrates the N.W. coast of India in the province of Guzerat about 80 miles. It is supposed that the depth of water in this gulf has been decreasing for more than two centuries past. The tides, which are very high, run into it with amazing velocity, but at low water the bottom is left nearly dry for some distance below the latitude of the town of Cambay. It is, however, an important inlet, being the channel by which the valuable produce of central Guzerat and the British districts of Ahmedabad and Broach is exported. The gulf extends between N. Lat. 21.—22. 10., E. Long. 71. 50.—72. 40.

CAMBAYES, cotton cloths made at Bengal, Madras, and elsewhere on the coast of Coromandel.

CAMBER, according to our monkish historians, one of the three sons of Brute, who, on his father's death, received as his inheritance that part of Britain called from him *Cambria*, now Wales.

CAMBERED DECK, among ship-builders, is one which is higher in the middle of the ship's length, and droops towards the stem and stern.

CAMBERT, ROBERT, the earliest composer of French comic operas, was born at Paris about 1628. He was organist of the church of St Honoré, and musical superintendent to Queen Anne of Austria, mother of Louis XIV. His earlier works, in which he was assisted by the Abbé Perrin, continued to be performed before the court at Vincennes, till the death of his patron Cardinal Mazarin. Enraged at his subsequent neglect, and jealous of the favour shown to Lulli, who was musical superintendent to the king, he retired to London, where he was appointed inspector of music to Charles II. His operatic pieces were entitled *Ariadne ou les Amours de Bacchus*, *Pomone*, and *Les Peines et les Plaisirs de l'Amour*. Cambert died in London about 1677.

CAMBERWELL, a village and parish in the county of Surrey, and one of the suburbs of London, being about two miles south from St Paul's. The population of the parish in 1851 amounted to 54,667. See LONDON.

CAMBIO, a Spanish word signifying *exchange*, used in Holland and some other countries.

CAMBIST (Italian *cambio*, exchange), a banker; one who deals in notes and bills of exchange.

CAMBODIA, or CAMBOJA, a kingdom of Asia formerly independent, but now partitioned between the kingdoms of Anam and Siam. It consists of a flat alluvial plain, traversed by the river Maekhaun or Camboja, and inclosed by two mountain ridges which separate it from the kingdom of Cochin-China proper on the east, and Siam on the west. On the north it is bounded by the kingdom of Laos; on the south by the Chinese Sea. Of the interior very little is known by Europeans. Near the coast the country is overgrown with wood, a little further inland the soil is fertile and well-cultivated, but beyond there seems to be only a vast jungle, where elephants, lions, tigers, and buffaloes find shelter, and are hunted by the natives for their ivory and skins. Deer, hogs, goats, and wild fowl abound in the forests and more cultivated districts. The principal productions are rice, betel, spices, sandal, ivory, eagle and rose woods, gamboge, and numerous other dye-stuffs. The principal tree that produces gamboge is the *Garcinia gambogioides;* and in Ceylon a similar gum-resin is the concrete juice of the *Hebradendron gambogioides*. The river Maekhaun falls into the sea by numerous mouths, which are navigable when in flood. In its course it sends off several branches on the eastern side, which, after inclosing large and fertile districts, return further down to the main stream. On the river Sai-gon, which intersects the eastern part of the province, stands the modern capital Sai-gon, while on the Maekhaun is the ancient capital Pontaipret or Camboja. The foreign commerce of the country is limited to China, and consists in the importation, for the most part in Chinese bottoms, of tea, china, and silk goods. Various attempts have been made by European merchants to establish a friendly intercourse with the inhabitants, but these have hitherto been attended with little success. The climate resembles that of Bengal. See COCHIN-CHINA.

CAMBORNE, a small town in the hundred of Penwith, county Cornwall. It is a neatly built place, and stands in the immediate neighbourhood of some of the most productive tin and copper mines in the county, which afford employment to most of the inhabitants. It has a handsome parish church, built in the later Gothic style, and several dissenting chapels principally belonging to the Wesleyan Methodists. Pop. 6547.

CAMBRAY, a fortified town of France, in the department of the Nord, and situated on the right bank of the Scheldt, 32 miles south of Lille. N. Lat. 50. 10., E. Long. 3. 14. The houses are pretty well built, and the fortifications have been improved according to Vauban's plan. The principal edifice is the cathedral church of St Sepulchre, a modern building erected on the site of the one which was destroyed at the French Revolution. It contains a monument by David raised to the memory of Fénélon, who was archbishop of Cambray, and consisting of three bas-reliefs illustrative of the various incidents of his life. He was buried in the ancient cathedral, but at the revolution his tomb was broken open and his coffin melted into bullets. Besides the cathedral there is the church of St Géry, the Hôtel de Ville, the public library containing upwards of 30,000 volumes, the archiepiscopal palace, and several other public buildings. It is the seat of a college, of a medical and ecclesiastical seminary, and of judicial and commercial tribunals of the first instance. Cambray is principally famous for the manufacture of fine muslin, called cambric, after the name of the town; but it also contains extensive manufactories of cotton and linen yarn, tulle, lace, black soap, sugar, brandy, saltpetre, &c. Its principal trade is in corn, wine, wool, flax, butter, hops, &c. The Scheldt begins to be navigable at Cambray, and communicates with St Quentin by means of a canal. Pop. 18,987.

Cambray is the ancient Nervian town of Camaracum, and was at one time the capital of an independent kingdom. It was fortified by Charlemagne; and the citadel was built in the middle of the sixteenth century by Charles V. It was taken by assault by the English in 1815 after the battle of Waterloo.

CAMBRIA, the ancient name of Wales.

CAMBRIC, a very fine linen fabric. It derived its name from Cambray in Flanders, where it was first manufactured. An excellent imitation of this fabric is woven from fine cotton yarn.

CAMBRIDGE, the chief town of the English county of the same name, is situated upon the banks of the river Cam, which is navigable to the sea by means of the river Ouse, falling into the sea at the port of Lynn. It is situated in an extensive and moderately fertile plain, and considered as very salubrious. Like most ancient towns it consists chiefly of narrow and winding streets, the houses in which differ very remarkably in their architecture. Several of the streets have recently been widened and improved by the removal of many ancient but picturesque houses, but some few singular mediæval habitations still remain, and it is hoped may be retained in future without interfering with the alterations required for modern convenience and the adoption of the measures for sanitary improvement. The most remarkable of the alterations has been the removal of

Cambridge. a long range of old buildings by which King's College was hidden from view, and the destruction of a mass of houses for the enlargement of the market-place. The beauty of the town has also been greatly increased by the numerous additions that have been made to the collegiate buildings during the last thirty years. There was certainly a Roman town upon a part of the site of modern Cambridge, but it is not certain by what name it was then called. The celebrated antiquary Dr Stukeley suggested that its name was Granta, but he seems to have had no good reason for that opinion, although some have believed it to have been the Caer Graunt of Nennius. It seems more probable that it is the place called Camboritum or Camboricum, in the Antonine Itineraries (Babington's *Ancient Cambridgeshire*). Some slight remains of its Roman fortifications may still be traced, but the greater part has long since been destroyed. The Roman town was situated on the north side of the river, but after being deserted during some part of the Saxon period the present town sprung up on the south side of the Cam.

Most of the public buildings belong to the university, which is a corporation having separate jurisdiction from the borough, and returns two members of its own to the House of Commons. The constitution of the university and its several colleges will be noticed separately under the head of universities. The principal buildings may, however, be noticed here. A few of them are, King's, Trinity, St John's, and Jesus Colleges, the university library, the Fitzwilliam Museum, and the Pitt Press. Of these the chapel of King's College is the most deserving of notice, both from its great beauty, and also as being one of the few perfect buildings in the florid form of the perpendicular style of architecture. A new set of county courts has recently been erected, which, although making considerable pretensions, is not a very successful specimen of architectural skill. The churches are numerous, and a few of them interesting. St Benedict's (or Bennet) church has a tower of true Romanesque architecture; St Sepulchre's, which is one of the few round churches in England, and is in the Norman style, has been very successfully restored; St Mary's, which is used by the university, is a fine building in the perpendicular style.

The town is governed by a mayor, 10 aldermen, and 30 common councillors, under the Municipal Reform act, but was formerly under a very ancient corporation. It has returned two members to parliament from the time of Edward I. There is a grammar-school founded by Dr Perse, in which a number of the sons of burgesses are educated gratuitously. There are several alms-houses of ancient foundation. The two fairs, once of much note and use, are now greatly neglected, and might probably be discontinued without any inconvenience. The trade of the town is almost wholly that resulting from its situation in the centre of an agricultural district; and the presence of the great number of students attending the university. It is a chief station upon the Eastern Counties railway, and at the head of the navigation for barges from the port of Lynn. It is the centre of a county court and excise district. The principal market is held on Saturday, and is well attended. There are two weekly newspapers published there. Pop. (1851) 27,815, of whom 13,347 were males, and 14,342 females. (C. C. B.)

CAMBRIDGE, a town in the county of Middlesex, state of Massachusetts, North America. It stands on the Charles river, three miles N.W. of Boston, with which it is connected by railway. It is the seat of Harvard University, formerly called Harvard College, the oldest and best endowed institution of the kind in the Union. See MASSACHUSETTS. Mount Auburn cemetery here is noticed in the article BOSTON. The town contains a court-house, jail, state arsenal, and numerous churches. Its observatory is in Lat. 42. 22. 48. N., Long. 71. 8. W. Pop. (1850) 15,215.

Cambridgeshire. CAMBRIDGESHIRE a county in the South Midland Division of England, is of a form which has been considered as somewhat resembling the human ear. The concave part is occupied by the county of Huntingdon. Its boundary is not easily traced in traversing the country, owing to the want of any marked natural features in the upland part, and the great change that has taken place in the course of the rivers and drains in the fen districts. It is divided by a part of the old course of the river Ouse into two nearly equal portions, constituting the county of Cambridge proper and the Isle of Ely, and by the last survey is found to contain about 548,480 acres, of which 248,430 belong to the Isle. Most of the land is arable, but the several parts differ from each other materially in character.

The whole of the Isle, and some portion of the other lands, form part of the great level of the fens, called the Bedford Level from the efforts made by the last earl and the successive dukes of Bedford to promote its drainage. During the Roman dominion in Britain this extensive district seems to have consisted chiefly of wet forests, intersected by stagnant rivers and marshes. That it was not altogether a morass at that time is shown by the great roads formed through it by that enterprising people. These are now covered in most places by many feet of peat soil, so that they are only to be seen when deep drains are cut in the mosses. Afterwards, during the Saxon, and especially the Norman periods, the whole was flooded by the silting up of the outfall of the rivers. This state of things became worse and worse, until, in the reign of Charles I., the whole district had become a number of islands, surounded by an almost constant flood of water. Since that time continual endeavours have been made to reclaim the flooded lands; and this has been pretty completely effected by embanking the rivers and other streams that convey the upland waters, and pumping the fen water into them by the aid of steam, which has superseded the numerous windmills formerly less effectively employed for the purpose. The singular changes which took place in the district during its neglected state may be illustrated by the fact, that at one period the rivers Nen, Ouse, and Cam, which poured their waters on to the level, all found their way to the sea at Wisbech; that subsequently, by the formation of a cut which still conveys the latter two conjointly by the Little Ouse to Lynn, the three took their course to that last mentioned town, and the Nen became so sluggish as to have no definite channel, but found its way through various and tortuous drains. At the present time, the Nen alone flows by an artificial course to Wisbech; and the old channel of the Great Ouse from Littleport to Wisbech is so completely filled up as to be only traceable by a bed of silt, and a slight but broad depression of the land. The Ouse formerly flowed from Earith, near which place it enters the county, to a spot some miles to the south of Ely, to be joined by the Cam; but is now conducted by a great artificial cut, called the Bedford river, in a direct course of more than twenty miles to Denver, in Norfolk; thus leaving many miles of its ancient channel nearly dry.

This fen country is now so well drained that almost the whole of it has become highly valuable land, much of which bears heavy crops of wheat. Few things can be more interesting to the observant traveller than a journey across this district by the Eastern Counties railway, which either by its main line or its branches passes through the fens in several directions. The fields divided by wet ditches, the constantly recurring bridges over the great drains, the passing of the artificial rivers, the high state of cultivation, the almost absolutely level country, present such a scene as is not to be found elsewhere in Britain. When contemplating it, we cannot avoid being struck by the success which has attended the application of great skill and con-

summmate energy and perseverance to the work of rendering available for agricultural purposes this extensive and once nearly useless tract.

Most of the fen country is based upon a bed of clay of great thickness, consisting of what are denominated by geologists the Gault, Oxford clay, and Kimmeridge clay. These, by the almost total absence of the strata of stone that usually separate them, have become only distinguishable by their imbedded fossils. Above the clay there is a deposit of peat of variable thickness, but usually of many feet. In those parts which formerly constituted the fen islands, there are great masses of gravel, sand, and sometimes drift-clay. The chief of these islands is that upon which the city of Ely is placed; and it is deserving of remark, that that city, which is now a central railway station, was at no distant date so inaccessible by land that the bishop always employed a boat when he was desirous of visiting Cambridge.

The drainage of the peat has deprived it of its former spongy character, and the underlying clay having been raised and mixed with it, they have together formed a highly fertile soil. With the exception of a very few and small pieces of unreclaimed land, the whole fen district is now as well farmed as almost any part of Britain.

We have not space to enter upon the highly interesting history of the drainage works, and must refer for full information upon the subject, to Dugdale's "Embarking," Wells's "Bedford Level," and a valuable paper in the 8th volume of the Journal of the Royal Agricultural Society of England. See Bedford Level.

Until a recent period the Isle of Ely was a separate jurisdiction, forming a palatinate belonging to the bishop of that see, but it is now combined in all essential particulars with the other part of the county.

Formerly ague was very prevalent in the fens, but drainage has much diminished its frequency, although attacks of it are still not uncommon, both there and in the bordering villages. Otherwise, it is far from being an unhealthy district.

The upland parts of Cambridgeshire, or the "Highlands" as they are called by the inhabitants, form a tolerably level tract, only broken by low hills of chalk on the side adjoining Essex and Suffolk. At the foot of the hills the lower bed of chalk is still quarried under the name of clunch. It was formerly much used for building purposes, as being easily worked, and very durable when protected from the weather. Much of the elaborate sculpture in Ely Cathedral is formed of it. The district adjoining these hills is based on a shallow bed of clunch, lying over the Gault, but separated from it by a thin layer of the upper greensand formation, in which there are many nodules of phosphate of lime. The surface of this tract is also varied by extensive deposits of gravel, and is generally fertile and well cultivated. The sheep-walks which formerly occupied the chalk-hills are now converted into arable land, and only those small portions of Newmarket Heath are left unbroken which are required for racing and training grounds.

The country extending from near Cambridge to the western edge of the county, lies at a rather higher level than the district intervening between it and the chalk-hills. It consists of a cold, wet, and unprofitable drift-clay not forming part of any of the regular strata. Much of this land was brought under the plough during the prevalence of a high price for wheat, but is now (1854) scarcely found to repay the expense of cultivation.

There is nothing peculiar in the agriculture of Cambridgeshire; for the local crops of hemp, flax, and saffron, for which it was once noted, have nearly or quite disappeared. The drainage of wet meadows near Cottenham has tended greatly to reduce the quantity of cheese made there. The same cause has lessened the quantity and injured the quality of the butter supplied to Cambridge market.

The whole of the upper district, or county proper of Cambridge, is traversed by numerous brooks, which combine to form the river Cam. One of the chief tributaries of this river (called the Ree) rises on the borders of Hertford, Bedford, and Cambridge shires, the other (named the Grant) has its source in Essex. These waters combine at a short distance above Cambridge, and flowing by Ely to Littleport, in the ancient channel of the Great Ouse, are thence conducted by the artificial cut already mentioned into the Little Ouse, and together with that stream reach the sea at Lynn. Even in the higher parts of the country many of the brooks do not run in their natural channels, for the fall is so slight that without careful and constant attention to them they would often stagnate and flood the land.

We have already spoken under the head of Cambridge of the buildings in that town, but must not omit to mention the beautiful cathedral at Ely. That church has been recently restored nearly throughout. Its nave is in the Norman, the quire is in the early English and decorated styles. Although the monastery was founded at Ely in the year 673, and restored in 970, it is confidently believed that no traces of buildings older than the Norman part of the cathedral now exist. The so-called conventual church is certainly not Saxon, and has been shown by Professor Willis to have probably been the infirmary of the monks. There are many highly interesting parish churches scattered over the county.

Cambridgeshire seems to have been rather thickly inhabited by the Romans. Numerous remains of their roads and villas, as well as many coins and much pottery, have been found. Several of their great lines of road passed through the county, and may still be faintly traced. Two of these crossed each other in the Roman station at Cambridge, and are usually called by antiquaries "The Akeman Street" and "The Via Devana." Another traversed the fens from Denver in Norfolk to near Peterborough. The "Erming Street" and "Icknield Way" pass for some distance through the county, but they are probably tracks used by the ancient Britons. The Romans formed great embankments against the sea along the shore of the Wash, from Lynn by Wisbech into Lincolnshire, which are still very conspicuous, although now usually at a considerable distance from the coast. They also seem probably to have had a navigable canal along the edge of the fens, in continuation southwards into this county of the "Car Dyke."

Whilst mentioning the antiquities, it would not be right to omit all notice of the four great boundary ditches, formed apparently before the time of the Romans, each of which extends for several miles across the open chalk district, from the fens to the ancient woodland. Of these, the Devil's Ditch, upon Newmarket Heath, is the best known It is also the largest, although one of the others is longer. Its length is about seven miles, and it consists of a ditch with a rampart on one side, formed of the excavated soil. The height of the bank is about eighteen feet above the level of the county, thirty above the bottom of the ditch, and twelve feet in width at the top. (Babington's *Ancient Cambridgeshire.*)

Much emigration has taken place from this county, and it is believed that the population is not now superabundant, although there are a few unemployed men in some of the country parishes and in the town of Cambridge.

In 1831 the population was 143,955, of whom 72,031 were males, and 71,924 females; in 1841 it amounted to 164,459, of whom 81,611 were males, and 82,848 females; and in 1851, to 185,405, of whom 92,699 were males, and 92,706 females. (C. C. B.)

CAMBYSES, a Persian noble, father of Cyrus the founder of the Persian empire. See Cyrus.

Cambyses, son and successor of Cyrus the Great. See Persia and Egypt.

CAMDEN, William, a celebrated antiquary, was born

in the Old Bailey, London, May 2, 1551. His father, who was a native of Lichfield, settled in London, where he became a member of the company of paper-stainers. His mother was of the ancient family of Curwen of Workington in Cumberland. Young Camden received his early education at Christ's Hospital and St Paul's school; and in 1566 he entered as a servitor of Magdalen College, Oxford; but being disappointed of a demi's place, he removed to Broadgate Hall, and, somewhat more than two years afterwards, to Christ Church, where he was supported by his kind friend and patron Dr Thornton. About this time he became a candidate for a fellowship at All Souls College, which he lost through the intrigues of the Popish party. In 1570 he supplicated the regents of the university to be admitted bachelor of arts, but in this also he was disappointed. The following year Camden came to London, where he prosecuted his favourite study of antiquity, under the patronage of Dr Goodman, dean of Westminster, by whose interest he was made, in 1575, second master of Westminster school. From the time of his leaving the university to this period, he made the tour of great part of England, with a view to make observations and collect materials for his celebrated *Britannia*, on which he was now seriously engaged. In 1581 he became intimately acquainted with the learned President Brisson, who was then in England, and in 1586 he published the first edition of his *Britannia*, a survey of the British isles, written in elegant Latin. This work which, though much enlarged and improved in future editions, was even then esteemed as an honour to its author and the glory of its country. In 1593 he succeeded to the head mastership of Westminster school, on the resignation of Dr Grant. In this office he continued till 1597, when he was promoted to be clarencieux king at arms. In 1600 Camden made a tour to the north, as far as Carlisle, accompanied by his friend Mr (afterwards Sir Robert) Cotton. In 1606 he began his correspondence with the celebrated President de Thou, which continued to the death of that faithful historian. In the following year he published his last edition of the *Britannia*, which is that from which the several English translations have been made; and in 1608 he began to digest his materials for a history of the reign of Queen Elizabeth. In 1609, after recovering from a dangerous illness, he retired to Chislehurst in Kent, where he continued to spend the summer months during the remainder of his life. The first part of his annals of the queen did not appear till 1615, and he determined that the second volume should not appear till after his death.[1] The work was entirely finished in 1617; and from that time he was principally employed in collecting more materials for the further improvement of his *Britannia*. In 1622, being now upwards of seventy, he determined to lose no time in executing his design of founding a history lecture in the university of Oxford. His deed of gift was accordingly transmitted by his friend Mr Heather to Mr Gregory Wheare, who was by himself appointed the first professor. Camden died at Chislehurst, Nov. 9, 1623, in the seventy-third year of his age, and was buried with great solemnity in Westminster Abbey, where a monument of white marble was erected to his memory. He was a man of singular modesty and integrity, profoundly learned in the history and antiquities of this kingdom, and a judicious and conscientious historian. He was respected and esteemed by the literati of the Continent, and will be ever remembered as an honour to the age and country in which he lived. Besides the works already mentioned, he was author of an excellent Greek grammar, and of several tracts in Hearne's collection. But his great and most useful work, the *Britannia*, is that upon which his fame is chiefly built. It was first translated into English, and published in folio in London in 1611, by Dr Philemon Holland, who is thought to have consulted the author himself; and therefore great respect has been paid to his additions and explanations, on a supposition that they may belong to Camden. But in a later edition of the same translation, published in 1636, the doctor has taken liberties which cannot be excused. A new translation, made with the utmost fidelity from the last edition, was published in 1695, by Edmund Gibson of Queen's College, Oxford, afterwards bishop of London; in which, besides the addition of notes, and of all that deserved to be taken notice of in Dr Holland's first edition, there are many other augmentations and improvements, all properly distinguished from the genuine work of the author; and the same judicious method was followed in the next edition of this performance. But afterwards there appeared a new translation and improved edition, by the learned and industrious topographer Mr Gough, under whose hands it was enlarged to nearly double the size of the last of the preceding editions.

Camden, a city and seaport, capital of the county of the same name, in the state of New Jersey, North America, stands on the east side of the Delaware river, opposite Philadelphia, and 29 miles S.S.W. of Trenton. The city consists of three parts, the central or principal part, and the northern and southern suburbs; from all of which there are ferries to Philadelphia. The largest ships can come up to the lower part of the city, and vessels of 150 tons to the central parts. The city has considerable trade and manufactures, and numerous fine public buildings. The Camden and Amboy railway, leading from New York, terminates here; and there is also a railway to Woodbury. Pop. 9618.

Camden, a village, capital of the Kershaw district in the state of South Carolina, North America, 33 miles N.E. of Columbia. It stands on the east bank of the Waterel river, by means of which flat-bottomed boats of 70 tons come up to the village. It contains a court-house, jail, academy, masonic-hall, market-house, library, arsenal, and about 1000 inhabitants. Two battles were fought here (1780–81) during the revolutionary war; and a fine marble monument has been erected to the memory of Baron de Kalb.

CAMEL. See Mammalia, and *Index*.

Camel, a machine, of Dutch invention, for raising large ships so far above the water-line as to enable them to pass over the obstruction of a bar or shallow. It consisted of two large boxes or half ships, which were applied to each side of the hull of a large vessel, and from which a number of cables were passed under the keel and attached to horizontal windlasses on the deck of either half of the camel. When the machine was to be used, water was allowed to enter so as to sink the two parts of the machine to the requisite depth; the ropes were then cast loose, and large beams were placed horizontally through the port-holes of the ship, with their ends resting on the camel on each side. When the ropes were made fast, and the ship properly secured, the water was pumped out of the camel, which then rose and bore up the ship along with it. By this contrivance, East Indiamen drawing 15 feet could be made to draw only 11 feet; and ships of war carrying 90 or 100 guns were enabled to pass the sandbanks of the Zuyder-Zee. (Beckmann's *Hist. of Inventions*, vol. iii. p. 338.)

This machine is also available for raising sunken vessels.

[1] The reign of Queen Elizabeth was so recent when the first volume of the annals was published, that many of the persons concerned, or their dependents, were still living. It is no wonder, therefore, that the honest historian should offend those whose actions would not bear inquiry. Some of his enemies were clamorous and troublesome, which determined him not to publish the second volume during his life; but, that posterity might be in no danger of disappointment, he deposited one copy in the Cotton Library, and transmitted another to his friend Dupuy at Paris It was first printed at Leyden in 1625.

CAMELEON. See REPTILIA (*Chamæleonidæ*).

CAMELFORD, a market-town in the parish of Lanteglos, and county of Cornwall, on the Camel, 12 miles N.N.E. of Bodmin. Previous to the Reform act it returned two members to parliament. Population of parish (1851) 1740.

CAMELLIA, a very ornamental genus of plants, natives of China and Japan, belonging to the natural order Ternstromiaceæ. A great many varieties of this plant are grown in England and Belgium, sometimes in the open air, but more generally in hothouses. Though usually cultivated in pots, they are found to thrive best in open soil in a glass-house artificially heated. See HORTICULTURE, and BOTANY.

CAMELOPARD, the giraffe. See MAMMALIA.

CAMENÆ, or CAMŒNÆ, also called *Carmenæ*, *Casmenæ*, certain prophetic nymphs connected with the religious worship of ancient Italy, though later traditions represent them as of Arcadian origin. The appellation is derived from *carmen* a "prophecy." Of these goddesses, the principal was Carmenta or Carmentis, who had a temple and altars at Rome. See CARMENTALIA. The muses are frequently called Camenæ by the Roman poets.

CAMEO. See CAMAIEU.

CAMERA ÆOLIA, a contrivance for blowing the fire, for the fusion of ores, by means of water falling through a funnel into a close vessel, which sends forth as much air or vapour as keeps up a constant blast. By the intervention of another vessel for the air to expand in by the way, it there deposits its humidity, which otherwise would impede the work.

CAMERA *Lucida*, a contrivance of Dr Hook for making the image of any thing appear on the wall of a room during sunshine. Opposite to the wall on which the image is to be received there is an aperture in the window shutter of at least a foot in diameter. The object being placed outside the aperture, it must be strongly illumined by a mirror which throws the sun's rays upon it. Between the object and the wall which is to receive the image place a large convex lens, whose focal distance is sufficiently great to give an image on the wall. In proportion as the lens is placed nearer the object, the image on the wall will be larger, and *vice versa*. (*Phil. Trans.* No. xxxviii. p. 741, *et seq.*) With a good lens, magnified images of objects, such as small gems in bas-relief, may be formed on a wall or screen so perfect as to appear like real bas-reliefs.

CAMERA *Lucida*, an instrument invented by Dr Wollaston for drawing in perspective.

If a piece of plain glass be fixed at an angle of 45° with the horizon, and if, at some distance beneath, there be a sheet of paper laid horizontally on a table, a person looking downwards through the glass will see an image of the objects situated before him; and as the glass which reflects the image is also transparent, the paper and pencil can be seen at the same time with the image, so that the outline of the image may be traced on the paper. The image is an *inverted* one. This is the simplest form of the instrument, and may be constructed extemporaneously by fixing on a stand a plain transparent glass, with its surfaces ground parallel, or a piece of Muscovy glass, at an angle of 45° with the horizon: a card with a small hole in it will serve as a sight for keeping the eye steady in one situation whilst the pencil is tracing the image.

If there be a plain mirror at an angle of 22½ degrees with the horizon, and a piece of plain transparent glass be placed near it, at an angle of 22½ degrees with the vertical, the rays from the object will be twice reflected before they reach the eye; and consequently, on looking down through the transparent glass, an *erect* image is seen, and the pencil may be drawn over the outlines of this image so as to leave a perspective representation on the paper. This disposition is seen at fig. 1, Plate CLV., where *bc* is the mirror, *ab* the transparent plain glass.

As the image and pencil are at different distances, they cannot be both seen in the same state of the eye. To remedy this inconvenience, a convex glass is used, of such focus as to require no more effort than is necessary for seeing the distant objects distinctly. By means of this lens, the image will appear as if it were placed on the surface of the paper. In fig. 1 *bd* is a convex glass of twelve inches focus; at *e* the eye is placed; *fghe* is the course of the rays proceeding from the object to the eye

Those whose eyes are adapted to seeing near objects alone, will not derive advantage from the use of a convex glass, but will require a concave glass to be placed at *f*, in the course of the rays from the object to the reflecting surface. In fig. 2, *ik* is a concave glass placed in the above-mentioned situation: it is so disposed as to be turned at pleasure into its place, as the sight of the observer may require. Persons whose sight is nearly perfect may use either the concave glass placed before the reflecting surface, or the convex glass placed between the paper and the eye.

In the actual construction of the instrument, a prism is used instead of a mirror and a plain glass. The rays from the object fall upon the surface *bc* of the prism, fig. 3. This surface *bc* is inclined 22½ degrees to the horizon. The refractive power of the glass allows none of the rays in this situation to pass out; they are all reflected from the surface *bc* to the surface *ab*, and from that to the eye. *ab* makes an angle of 135 degrees with *bc*, and 22½ degrees with the vertical. The eye cannot see the pencil through the prism as it does through a plain glass; therefore, in order that the pencil may be seen, the eye must be so placed that only a part of the pupil may be above the edge of the prism, as at *e*, fig. 3; and then the reflected image will be seen at the same time with the paper and pencil. There is a small piece of brass perforated with a hole *c*, and moving on a centre, fig. 2; this serves to keep the eye in one position, as it must be, that the image may be steady, and also to regulate the relative quantities of light to be received from the object and from the paper.

The instrument, being near the eye, does not require to be large. The smallest size which can be executed with accuracy is to be preferred, and is such that the lens is only three fourths of an inch in diameter. Fig 4 shows the instrument on its stand, and clamped to a board. The joint by which the prism is attached to the stand is double. The whole instrument packs in a box eight inches by two, and half an inch deep.

This instrument serves for drawing objects of all forms. and consequently also for copying lines already drawn on a plain surface. If it is required that the copy shall be of the same size as the original drawing, the distance of the drawing from the prism should be the same as the distance of the paper from the eye-hole. No lens will be necessary in this case, because the image and the paper, being both at the same distance from the eye, coincide without the aid of a glass.

In order to have a reduced copy of a drawing, the drawing is to be placed at a distance from the prism greater than the distance of the paper from the eye-hole. If the distance is twice as great, a copy will be obtained in which the lines are of one half the size of the lines in the original, and so in proportion for other distances. A lens is necessary, that the eye may be enabled to see at two different distances; and, in order that one lens may serve, the distance between the eye-hole and the paper should be variable; to that effect the stand is susceptible of being lengthened or shortened at pleasure.

The length of the stem is adjusted upon optical principles. When a distant object is to be delineated, the rays coming from it, and reflected by the instrument to the eye, are parallel, and it is required that the rays proceeding from the paper to the eye should also be parallel. This is accomplished by interposing a lens between the paper and the eye, with its principal focus on the paper. When the object to be delineated is so near that the rays which come from it to the eye are divergent, then it is required that the rays from the paper should likewise be divergent in the same degree, in order that the paper and the image may both be seen distinctly by the same eye; for this purpose the lens must be placed at a distance from the paper less than the distance of its principal focus. The stem of the instrument is marked at certain distances, to which the conjugate foci are in the several proportions of 2, 3, 4, &c. to 1, so that distinct vision may be obtained in all cases by placing the original drawing more distant.

If the convex lens be transposed to the front of the prism, and the proportional distances be reversed, a magnified image of the object will be obtained.

This instrument has deservedly come into use. Its advantages, when compared with the camera obscura, are, 1*st*, That it is small and easily carried about. 2*dly*, That no lines are distorted, not even those most remote from the centre; whereas, in the camera obscura, the lines which are not near the centre of the field are more or less distorted. 3*dly*, In the field of the camera lucida 70 or 80 degrees may be included, whilst the distinct field of the camera obscura does not extend beyond 30 or 35 degrees at most. The specification of Dr Wollaston's patent for the camera lucida is inserted in the *Repertory of Arts*, vol. x. 1807, p. 162, and his description of the instrument in Nicholson's *Journal*, vol. xvii.

The camera lucida employed by Captain Hall packs in a small box. When the instrument is to be used the box folds out and forms a small table, which is fixed on the top of a tripod. There is a folding three-legged seat, which packs within the tripod. The tripod, when closed and containing the seat, is only the size of a walking stick.

If the camera lucida be fixed at the eye-glass of a telescope, it will reflect to the eye the image of the objects in the field of the telescope, so that a drawing of the image may be made. See Dr Brewster's *Account of some Philosophical Instruments.* A plain reflecting glass, fixed at an angle of 45 degrees with the horizon, and placed so as to receive the rays from the eye-glass of a telescope, will also give an image of the objects in the field, so situated that the image may be traced with a pencil. Varley's patent graphic telescope is upon this principle. In order that the field may be large, the magnifying power of the telescope should be small.

The inherent qualities of all the instruments for drawing in perspective being closely allied, it will be proper to say something of the principles on which these instruments are formed, and to mention some that are not described in other parts of this work.

To make a perspective drawing of an object is to lay down on paper a section of the perspective cone, whose apex is at the eye, and whose base is the object. An experienced draughtsman can draw the figure of this section without the aid of instruments. Others who have not acquired the facility of drawing the image they see, must have recourse either to *measurement*, or to *instruments which bring the image under the pencil.*

Drawing by measurement is performed by actually measuring the height of the principal parts of the object, and their horizontal distance from the eye; together with the distance of the paper from the eye; and from these dimensions the drawing is constructed by the systematic rules of perspective.

Another mode of obtaining a drawing by measurement is to measure the angles at the eye. Suited to this purpose are theodolites, astronomical quadrants, or other instruments capable of measuring vertical and azimuthal angles at the eye. The angles to be measured are, the angles of altitude, and the angles of azimuth, between the point of sight and the principal points of the object; and if the tangents of the azimuthal angles be laid down with a radius equal to the distance of the paper from the eye, and the tangents of the angles of altitude with a radius equal to the distance of the paper multiplied by the secant of the azimuth, the situation of the principal points of the drawing will be determined. Or, if the instrument is capable of measuring angles in any plane, the angles between the principal points of the object and the point of sight are to be observed, and the azimuthal angles of these principal points with the point of sight; and the tangents of both are to be laid down on the paper, with a radius equal to the distance of the paper from the eye.

But these two modes by measurement are long, particularly the first. Usually, therefore, the instruments to which recourse is had for facilitating the operation of drawing, are such as give an image or section of the perspective cone on a plain surface, so that the pencil may be drawn over the outline of the image. These instruments may be considered under two heads; the first comprehending those in which the pencil is immediately drawn over the lines of the image; the second those in which the pencil has a motion parallel to that of the point which moves over the lines of the image.

Of the first kind are the following. 1. The tracing pane, a very simple and convenient instrument, consisting in a transparent plate of plain ground glass, or of Muscovy glass, placed vertically between the object and the eye; whilst the eye is kept fixed by a sight, the outline of the image is drawn on the glass with Indian ink. 2. Or the upright glass may be divided into small squares by lines crossing each other, and the paper on which the drawing is to be made being similarly divided, the particular intersections on the glass that cover the principal points of the object are observed, and these points are laid down on the corresponding intersections on the paper. 3. The image seen in a plain mirror may also be drawn on its surface with Indian ink. 4. In the camera obscura, different forms of which are described in the *Encyclopædia* under the articles Dioptrics and Optics, the image to be drawn is formed at the focus of a lens. 5. In the camera lucida the reflected image is used.

In the second division of the instruments which give a section of the perspective cone susceptible of being delineated, the pencil does not move immediately over the lines of the image, but moves parallel to these lines. 1. There is a rod which can be moved in all directions, consistent with its remaining parallel to itself. If one extremity of this rod be moved in space over the outlines of the image which the eye sees, a pencil at the other extremity will necessarily move with a similar motion, and form a drawing of the object on paper. In Sir Christopher Wren's instrument, of which he has given the description and figure in the *Philosophical Transactions*, vol. iv., the rod is suspended by strings passing over pullies, and the ends of the strings are fixed to a counterpoise. On a similar principle is Peacock's instrument, described in the *Philosophical Transactions*, vol. lxxv., p. 366, and the instruments treated of in the *Stockholm Transactions* for the years 1760, 1774, and 1790. A well-constructed instrument on this principle, and for which there is a pa-

tent,[1] is to be found now (1831) at Mr Cary's in the Strand. 2. The pencil may delineate the base of a cone similar and opposite to the perspective cone. If the rays from the extreme points of an object cross on the ray from the centre, as they do in passing through a small hole into a dark room, and if it be supposed that, in the place of one of the rays a slender inflexible rod is substituted moveable on a centre at the hole, when this rod is moved so that its outer extremity goes over the outlines of the external image, a pencil fixed to its inner extremity will form an inverted drawing of the object. Of this nature is the optigraph of Ramsden and Thomas Jones, described in the *Philosophical Magazine*, vol. xxviii., 1807, p. 67. The image of the object is seen in a telescope. There is a piece of plain glass near *c* in the focus of the eye-glass of the telescope F, fig. 5. On the centre of this piece of glass is a dot; *a* is a plain mirror, inclined so as to reflect the image of the object down into the telescope. This mirror remains fixed, whilst the telescope is moveable on a universal joint at its object-glass *b*. Near *c* is another plain mirror, which reflects the rays to the eye-glass. The eye being placed at the eye-glass at *e*, the telescope is to be moved by the handle *h*, so that the dot in the focus of the eye-glass shall pass over the outlines of the image seen by the eye, and the pencil at L performing a similar motion to that of the dot, and sliding freely in its sheath, presses with its weight on the paper: a drawing of the object is the result. If the stand and slider H be lengthened, an enlarged drawing will be obtained. The instrument packs in a box 14 inches by 6 and 3.

The instrument used for drawing profiles of the face consists of a long rod which moves on a joint. One end of the rod is moved over the face, the other end, which terminates in an iron point, describes the profile on paper. Professor Wallace of Edinburgh constructed an improved drawing instrument, which he has denominated an Eidograph. This instrument is described under the head EIDOGRAPH. It is of the nature of the pantograph, and serves for copying and reducing. (W.A.C.)

CAMERA *Obscura* (*i.e. Dark Chamber*), in *Optics*, a machine or apparatus representing an artificial eye, by which the images of external objects, received through a double convex glass, are exhibited distinctly, and in their native colours, on a white board placed within the machine, or on the focusing glass. The invention of this instrument is due to Friar Bacon, though by some it has been ascribed to Baptista Porta.

The *camera obscura* affords very diverting spectacles, by representing images perfectly like their objects, while at the same time it exhibits all their motions. By means of this instrument, a person unacquainted with designing may delineate objects with the greatest accuracy. Its use in photography will be found under that head.

CAMERALISTICS, (German *cameral*, financial), the science of finance.

CAMERARIUS, JOACHIM, whose real name was Liebhard, one of the most learned writers of his time, was born at Bamberg in 1500. He translated into Latin Herodotus, Demosthenes, Xenophon, Euclid, Homer, Theocritus, Sophocles, Lucian, Theodoret, Nicephorus, and other Greek writers. He published a Catalogue of the Bishops of the principal Sees; Greek Epistles; Accounts of his Journeys, in Latin verse; a Commentary on Plautus; the Lives of Helius Eobanus Hessus, and Philip Melanchthon, &c. He died at Leipsic in 1574.

CAMERARIUS, *Joachim*, a learned physician, son of the preceding, was born at Nuremberg in 1534. After having finished his studies in Germany, he visited Italy, where he was greatly esteemed by the learned. At his return he was invited to reside at the courts of several princes; but he was too much devoted to the study of chemistry and botany to accept their offers. He wrote a Hortus Medicus and several other works, and died in 1598.

CAMERINO, the capital of a delegation of the same name in the States of the Church, 40 miles S.S.W of Ancona. It is the seat of an archbishopric, and has a cathedral, several churches and convents, an archiepiscopal palace, and a university. Pop. 5200. The delegation has an area of 320 square miles, and a pop. of 38,415.

CAMERLINGO (German *Kämmerling*), according to Du Cange, originally signified the treasurer of the pope or the emperor. The title is now only used at Rome, where it is applied to the cardinal who governs the ecclesiastical state and administers justice. It is the most important office at the court of Rome, because he who holds it is at the head of the treasury. During a vacation of the papal chair, the cardinal camerlingo publishes edicts, coins money, and exercises every other prerogative of a sovereign prince. He has under him a treasurer-general, auditor-general, and twelve prelates called *clerks of the chamber*.

CAMERON, JOHN, a theologian of great erudition, was born at Glasgow about 1579, and received his early education in his native city. He was employed in teaching the Greek language in the university for twelve months; and then he embarked for France. Arriving at Bordeaux, he recommended himself to the favour and friendship of two Protestant clergymen by his agreeable manners, ingenuous disposition, and uncommon skill in the Greek and Latin languages. He spoke Greek with as much fluency and elegance as other persons could speak Latin—a proficiency that excited the admiration of Casaubon, with whom he soon afterwards became intimately acquainted. One of the pastors of the church of Bordeaux was his own countryman Gilbert Primrose, D.D., who was himself a man of learning. Through the recommendation of these clergymen, he was appointed a regent in the College of Bergerac, where it was his province to teach the classical languages; but thence he was speedily withdrawn by the Duc de Bouillon, who appointed him a professor of philosophy at Sedan. Here he acquired new reputation; and the duke next made him an offer of the Greek chair, which however he declined, on the plea that he could not accept it without depriving a friend of his office.

Having continued two years at Sedan, he resigned his professorship, and, after visiting Paris, returned to Bordeaux. In the beginning of 1604, he was nominated one of the students of divinity who were maintained at the expense of the church, and who for the period of four years were at liberty to prosecute their studies in any Protestant seminary. During this period he acted as tutor to the two sons of Calignon, chancellor of Navarre. They spent one year at Paris, and two at Geneva, whence they removed to Heidelberg, where they remained nearly twelve months. In this university, on the 4th of April 1608, he gave a public proof of his ability by maintaining a series of theses, "De triplici Dei cum Homine Fœdere," printed among his works. The same year he was recalled to Bordeaux, where he was appointed the colleague of Dr Primrose; and when Gomarus was removed to Leyden, Cameron in 1618 was appointed professor of divinity at Saumur, the principal seminary of the French Protestants. The principal of the college was at this time Dr Duncan, another of his learned countrymen, who were then so numerous in France. Cameron had already published several of his works, and his celebrity was in no small degree increased by his academical lectures.

In 1620, the progress of the civil troubles in France

[1] This *patent* instrument is the same in principle, and almost identical in form, with an instrument figured and described in an old work on Perspective, Joannis Francisci Niceronis *Thaumaturgus Opticus*, pars 1. Printed at Paris in 1646.

obliged Cameron to seek refuge in England for himself and family. For a short time he read private lectures on divinity in London; and in 1622 the king appointed him principal of the university of Glasgow in the room of Robert Boyd, who had been removed from his office in consequence of his adherence to the cause of presbytery. His successor appears to have been more favourably inclined to episcopacy; a circumstance that may have tended to diminish the cordiality of his reception in his native city. Here he likewise taught divinity with great reputation, but he resigned his office in less than a year. Calderwood says that "Cameron was so misliked by the people that he was forced to quit his place soon afterwards."

He returned to France, and fixed his residence at Saumur; and after an interval of a year he was appointed professor of divinity at Montauban. The country was still torn by civil and religious dissensions; and as Cameron maintained the doctrine of passive obedience, he excited the indignation of the more strenuous adherents of his own party. He withdrew to the neighbouring town of Moissac; but he soon returned to Montauban, and a few days afterwards he died at the age of about forty-six. Cameron left by his first wife several children, whose maintenance was undertaken by the Protestant churches in France.

In his person, Cameron was of the middle size, and somewhat spare; his hair was yellow, his eyes were brilliant, and the expression of his countenance was lively and pleasant.

Soon after the death of Cameron, his friends published his "Prælectiones in selectiora Loca Novi Testamenti." Salmurii, 1626–8, 3 tom. 4to. The editor was his learned pupil Louis Cappel, professor of Hebrew, and afterwards of divinity, in the university of Saumur; to whom we are likewise indebted for a sketch of the author's life and character. A collection of his theological works appeared under the title of "Joannis Cameronis, Scoto-Britanni, Theologi eximii τα σωζομένα, sive Opera partim ab auctore ipso edita, partim post ejus obitum vulgata, partim nusquam hactenus publicata, vel e Gallico idiomate nunc primum in Latinam linguam translata: in unum collecta, et variis indicibus instructa." Genevæ, 1642, fol. Cappel's *Icon Joh. Cameronis* is here reprinted. The writer of the preface to the volume was Frederic Spanheim, professor of divinity at Geneva. Cappel had published another work of his preceptor, which is not included in this collection: "Myrothecium Evangelicum, in quo aliquot Loca Novi Testamenti explicantur: una cum Spicilegio Ludovici Capelli de eodem argumento, cumque 2 Diatribis in Matth. xv. 5 de Voto Jephtæ." Genevæ, 1632, 4to. Another edition appeared under the subsequent title: "Myrothecium Evangelicum; hoc est, Novi Testamenti Loca quamplurima ab eo, post aliorum labores, apte et commode vel illustrata, vel explicata, vel vindicata. Quibus adjectæ sunt Alexandri Mori Notæ in Novum Fœdus, jam antea editæ, et Dissertatio in Mat. c. 24. v. 28. hactenus inedita: nec-non ejusdem A. Mori Axiomata Theologica, quæ nunc primum in lucem prodeunt. Editio novissima, locorum indicibus locupletata." Salmurii, 1677, 4to.

The name of this distinguished person furnished a denomination to a party of Calvinists in France, who asserted that the will of a man is only determined by the practical judgment of the mind; that the cause of men's doing good or evil proceeds from the knowledge which God infuses into them; and that God does not move the will physically, but only morally, by virtue of its dependence on the judgment of the mind. This peculiar doctrine of grace and free will was adopted by Amyraut, Cappel, Bochart, Daillé, and others of the more learned among the reformed ministers, who judged Calvin's doctrines on these points too harsh. The Cameronites are a sort of mitigated Calvinists, and approach to the opinion of the Arminians. They are also called Universalists, as holding the universality of Christ's death; and sometimes Amyraldists. The rigid adherents to the synod of Dort accused them of Pelagianism, and even of Manicheism; and the controversy between the parties was carried on with a zeal and subtilty scarcely conceivable; yet the whole question between them was only, whether the will of man is determined by the immediate action of God upon it, or by the intervention of a knowledge which God impresses on the mind. The synod of Dort had defined that God not only illuminates the understanding, but gives motion to the will by making an internal change therein; whereas Cameron only admitted the illumination by which the mind is morally moved, and explained the sentiment of the synod of Dort so as to make the two opinions consistent.

Cameron, *Richard*, the founder of the Cameronians, was born at Falkland, in the county of Fife. His father, who was a shopkeeper in that town, gave him such an education as the village school afforded; and his success was so great, that while still a youth he was appointed schoolmaster. In this situation he had opportunities of becoming acquainted with some of the more violent field-preachers, who at this time wandered through the country disseminating their doctrines as they went. Persuaded by them, he resigned his situation, and shortly after entered the family of Sir Walter Scott of Harden, as chaplain and tutor. He did not remain here long however; for refusing to acknowledge the Indulgence, he joined the ranks of the non-conforming ministers, and incited the inhabitants of the southern counties of Scotland to protest openly against the new edict. So formidable was the agitation that the government thought fit to interfere, and pronounced illegal all armed assemblages for religious purposes. Cameron was obliged to take refuge in Holland, where he resided for some time; but in the spring of 1680 he returned to Scotland, and once more made himself formidable and obnoxious to the government. Shortly after the defeat of the Covenanters at Bothwell Bridge in that year, Cameron was slain in a skirmish at Ayr's Moss, fighting bravely at the head of the few troops he had been able to collect.

CAMERONIANS. See Presbyterians, Reformed.

CAMEROONS, a river of Africa in Upper Guinea, falling into the bight of Biafra, about Lat. 4. N., Long. 9. 40. E. Cameroons peak, the highest point of the Cameroon mountains, being 13,000 feet above the sea, is in Lat. 4. 13. N., Long. 9. 10. E.

CAMILLI and Camillæ, boys and girls who ministered in the religious rites and ceremonies of the Romans, and especially those employed in the sacrifices of the Flamen Dialis, or priest of Jupiter. They were required to be free-born, perfect and unblemished in form, and the children of living parents. The origin of the word camillus (or casmillus, as it is sometimes written) has been connected with the Samothracian Kabiren-Hermes, Κάδμιλος and Κάδμος; but its etymology is in fact quite uncertain.

CAMILLUS, Marcus Furius, one of the most illustrious heroes of the Roman republic. He triumphed four times, was five times dictator, and was honoured with the appellation of Second Founder of Rome. When accused of having unfairly distributed the spoil taken at Veii, he anticipated judgment, and went voluntarily into exile at Ardea. But during his exile, instead of rejoicing at the devastation of Rome by the Gauls, he exerted all his wisdom and bravery to drive away the enemy, and yet kept with the utmost strictness the sacred law of Rome, in refusing to accept the command, which was offered him by several private persons. The Romans, when besieged in the capitol by the Gauls, created him dictator; and in this capacity he acted with so much bravery and conduct, that he entirely drove the enemy out of the territories of the commonwealth. He died of the plague in the eighty-first year of his age, B.C. 365. The famous story of Camillus and the schoolmaster belongs to the campaign against the

Faliscans, B.C. 394. It is said that when Camillus appeared before Falerii, a schoolmaster attempted to betray the town by bringing into his camp the sons of some of the principal inhabitants of the place. Camillus, indignant at such baseness, ordered that the traitor should have his hands tied behind him, and thus be whipped into the town by his own scholars. It is said that the Faliscans were so affected by the generosity of the Roman general that they immediately surrendered. (Livy; Plutarch.) See ROMAN HISTORY.

CAMIS, or KAMIS, in the *Japanese mythology*, the deified souls of ancient heroes, who are supposed still to interest themselves in the welfare of those they once commanded.

CAMISADE an attack by surprise at night or at break of day, when the enemy is supposed to be asleep. The word is said to have taken its rise from an attack of this kind, in which, as a badge by which to distinguish each other, the attacking party wore over their dress a shirt, in French called *chemise*, or *chamise*.

CAMISARDS, a name given to the Calvinists of the Cevennes, who took up arms in their own defence in 1688, after the revocation of the edict of Nantes. The origin of the name is given under CAMISADE.

CAMLET, or CAMBLET, a stuff made sometimes of wool, sometimes of silk, and sometimes of hair, especially that of goats, with wool or silk. In some, the warp is silk and wool twisted together, and the woof is hair.

The true Oriental camlet is made of the hair of a sort of goat frequent about Angora, and which constitutes the riches of that city. Camlets are now made in Europe. Writers of the middle age mention stuffs of camel's hair, under the denominations of *cameletum* and *camelinum*, whence probably the term; but these are represented as coarse and rough, and seem to have been chiefly used among the monks by way of mortification, as the hair shirt of later times.

CAMOËNS, LUIS DE, the most illustrious of the Portuguese poets, was born at Lisbon in 1517. His family was of considerable note, and originally Spanish. In 1370 Vasco Perez de Camoëns fled in disgust from the court of Castile to that of Lisbon, where King Ferdinand immediately admitted him into his council, and gave him the lordships of Sardoal, Punhete, Marano, Amendo, and other lands of considerable extent, a certain proof of the eminence of his rank and abilities. In the war of the succession, which broke out on the death of Ferdinand, Vasco sided with the king of Castile, and was killed in the battle of Aljabarota. But though John I., the victor, seized a great part of his estate, his widow, the daughter of Gonzalo Tereyro grand master of the order of Christ and general of the Portuguese army, was not reduced beneath her rank. She had three sons who took the name of Camoëns. The family of the eldest intermarried with the first nobility of Portugal, and even, according to Casterra, with the blood royal; but the family of the second brother, whose fortune was slender, had the superior honour of producing the author of the *Lusiad*.

The misfortunes of the poet commenced early in life. In his infancy Simon Vaz de Camoëns his father, commander of a vessel, was shipwrecked at Goa, where he perished, together with the greater part of his fortune. His mother, however, Anne de Macedo of Santarem, provided for the education of her son Luis at the university of Coimbra, where he acquired an extensive knowledge of the classics. When he left the university he appeared at court. He was handsome, with expressive eyes and a fine complexion; and as he was a polished scholar, this, added to the natural ardour and vivacity of his disposition, rendered him an accomplished gentleman. Having become deeply enamoured of Donna Catharina d'Alayada one of the queen's ladies, who, it appears, returned his passion, Camoëns was in consequence banished from court.

He now retired to his mother's friends at Santarem, where he renewed his studies, and began his poem on the discovery of India. At this time John III. was preparing an armament against Africa; and Camoëns, tired of an obscure and inactive life, went to Ceuta with the expedition, and greatly distinguished himself by his valour in several encounters. In a naval engagement with the Moors in the Straits of Gibraltar he was among the foremost to board, and lost his right eye in the conflict. Yet neither the hurry of actual service, nor the dissipation of a camp, could stifle his genius. He continued his *Lusiadas*, and several of his most beautiful sonnets were written in Africa, while, as he expressed it, "one hand the pen, and one the sword employed." The fame of his valour having reached the court, he obtained permission to return to Lisbon, where he found that his beloved Catharina was dead. He solicited an establishment which he had merited in the ranks of battle; but the malignity of evil tongues, as he expresses it in one of his letters, was poured out upon him. Stung by such ungrateful treatment, Camoëns resolved to bid his country a final farewell; and accordingly, in 1553, he sailed for India. As the ship left the Tagus he exclaimed, in the words of the sepulchral monument of Scipio Africanus, *Ingrata patria, non possidebis ossa mea;* "ungrateful country, thou shalt not possess my bones." But he knew not what evils in the East would awaken the remembrance of his native land.

When Camoëns arrived in India, an expedition was ready to sail to avenge the king of Cochin on the king of Pimenta. Without allowing himself any rest on shore after his long voyage, he joined this armament, and in the conquest of the Alagada islands displayed his usual bravery. In the following year he attended Manuel de Vasconcello in an expedition to the Red Sea, where, as he had no use for his sword, he employed his pen, and also visited Mount Felix and the adjacent part of Africa, which he so strongly pictures in the *Lusiad*, and in one of his sonnets, in which he bewails the loss of his Catharina. When he returned to Goa he enjoyed a tranquillity which enabled him to bestow attention on his epic; but this serenity was interrupted by his own imprudence; for he wrote some satires which gave offence, and by order of the viceroy, Francisco Barreto, he was banished to China.

But the accomplishments and manners of Camoëns soon procured him friends. He was appointed commissary in the island of Macao, a Portuguese settlement in the bay of Canton, where he continued his *Lusiad;* and, after five years' residence, he acquired a fortune, small indeed, yet equal to his wishes. A new viceroy, Dom Constantine de Braganza, having been appointed, Camoëns obtained his permission to return to Goa, and set sail in a ship freighted by himself; but he was shipwrecked in the passage on the coast of Cambodia, and all he had acquired perished in the waves. His poems, which he held in one hand while he swam with the other, were all he found himself possessed of when he stood friendless on an unknown shore.

On the banks of the Mecon he wrote his beautiful paraphrase of the psalm *Super flumina Babylonis*, where the Jews, in the finest strain of poetry, are represented as hanging their harps on the willows by the rivers of Babylon, and lamenting their exile from their native land. Here Camoëns continued some time, till an opportunity offered of a passage to Goa. When he arrived at that city, Dom Constantine de Braganza, the viceroy, admitted him to his friendship, and Camoëns continued happy till Count Redondo assumed the government. While Constantine continued in power, those who had formerly procured the banishment of the satirist were silent; but now they exerted all their arts against him. Redondo, when he entered upon office, however, pretended to be the friend of Camoëns; yet with unfeeling indifference he suffered the innocent man to be thrown into the common prison. After much delay, Camoëns in a public trial fully refuted every accusation

directed against his conduct while commissary at Macao, and his enemies were loaded with ignominy. Camoëns, however, had contracted certain necessary debts, and his creditors detained him in prison till some spirited townsmen of Goa, ashamed that a man of his singular merit should experience such treatment among them, procured his release. Once more he assumed the profession of arms, and received the allowance of a gentleman volunteer, a character at this time common in Portuguese India. Soon afterwards Pedro Barreto, appointed governor of the fort at Sofala, allured the poet by high promises to attend him thither. The governor of a distant fort in a barbarous country shares in some measure the fate of an exile; yet, though the only motive of Barreto was to enjoy the conversation of Camoëns at his table, he took no care to render the life of his guest agreeable. Chagrined at his treatment and weary of a state of dependence, Camoëns resolved to return to his native country. A ship on the homeward voyage at this time touched at Sofala, and several of the passengers were desirous that Camoëns should accompany them; but this the governor ungenerously endeavoured to prevent, and charged him with a debt for board. Anthony de Cabra, however, and Hector de Sylveira, paid the demand; and Camoëns and the honour of Barreto were discharged together.

After an absence of sixteen years, Camoëns in 1569 returned to Lisbon, unhappy even in his restoration to his native country, for the pestilence then raged in the capital. At last, in 1572, he printed his *Lusiad*, which, in the opening of the first book, he addressed to the youthful king Sebastian, who was so pleased with its merit that he gave the author a pension of four thousand reals, on condition that he should reside at court; but on the death of his patron, who fell in the battle of Alcazar in 1578, this pension was withdrawn by Cardinal Henry, who succeeded to the throne. Under his inglorious reign Camoëns died in all the misery of poverty. He was even indebted for the means of sustenance to an old Javanese servant, named Antonio, who begged in the streets of Lisbon for the only man in Portugal on whom God had bestowed those talents which had a tendency to elevate the spirit of a declining age. To the eye of a faithful observer, the fate of Camoëns throws great light on that of his country. The same ignorance and the same degenerate spirit which suffered Camoëns to depend on his share of the alms begged in the streets by his aged servant, sunk the kingdom of Portugal into the most abject vassalage ever experienced by a conquered nation. But while the grandees of Portugal were blind to the ruin which impended over them, Camoëns beheld it with a poignancy of grief which hastened his end. In one of his letters he has these remarkable words: "I am ending the course of my life; the world will witness how I have loved my country. I have returned not only to die in her bosom, but to die with her." In an alms-house at Lisbon, in 1579, died, at the age of sixty-two, Luis de Camoëns, the greatest genius Portugal ever produced; in martial courage and spirit nothing inferior to her most honoured heroes.

Fifteen years after his death, a monument was erected to his memory. Death had allayed all jealousies; and the homage due to him, as the national poet of Portugal, was now enthusiastically paid. The genius of Camoëns was inspired by the history of his country and the manners of his age; his lyric poems in particular, like the works of Dante, Petrarch, Ariosto, and Tasso, belong to romantic and chivalrous rather than to purely classical literature; and hence the partizans of the latter, who were very numerous in his time, were far from greeting with applause the first steps of his career. Of the *Lusiad* it would be superfluous to offer any criticism in this place. Suffice it to say, that with many faults, both of design and execution, it possesses perfect unity of interest, arising from the patriotic sentiment with which it is animated throughout, and charms alike by the stateliness and the grace of its versification, which foreigners as well as native Portuguese can relish and appreciate. The most esteemed edition of the works of Camoëns appeared at Lisbon in 1779–1780, under the title of *Obras de Luis de Camoëns principe dos poetas de Hespanha*, 4 tom. 12mo. A second edition also appeared in 1782–1783, the first volume of which contains the life of the author and the *Lusiad*, and the last his dramatic and other pieces. A splendid and correct, but very scarce edition of the *Lusiad* was published, with fine engravings, by Firmin Didot, Paris, 1817, 4to. It has been translated into several languages, and twice into English, by Fanshawe and Mickle.

CAMOMILE, or more properly CHAMOMILE, the flowers of the *Anthemis nobilis*. The flowers have a white ray with a central yellow disk, and have an aromatic bitter taste and a powerful odour. The infusion of the flowers is when cold a useful stimulant, bitter or tonic; the infusion taken warm, however, acts as an emetic. The virtues reside in a volatile oil, and in a bitter principle, which may be separated from one another.

CAMP, the ground on which an army pitch their tents. See WAR.

The Hebrew camp during the Exodus was of a quadrangular form, surrounded with an inclosure of the height of ten handbreadths. It formed a square of twelve miles in compass about the tabernacle; and within this was another called the *Levites' camp*.

The Greek camps were fortified with gates and ditches. The Lacedæmonians formed their camps in a circular shape. Of other Grecian camps it may be observed, that the most valiant soldiers were placed at the extremities. Thus in the Iliad, Achilles and Ajax were stationed at the extremities of the camp before Troy.

The figure of the Roman camp (*castra*) was a square divided into two principal parts. In the upper part were the general's pavilion, or *prætorium*, and the tents of the chief officers; in the lower were those of inferior degree. On one side of the *prætorium* stood the *quæstorium*, or quarters of the treasurer of the army; and near this the *forum*, called also *quintana*, where things were sold and meetings held. On the other side of the *prætorium* were lodged the *legati;* and below it the tribunes had their quarters, opposite to their respective legions. In this part of the camp also were the tents of the *præfecti* of the foreign troops, as well as those of the *evocati*, and of the *extraordinarii* and *ablecti*, both horse and foot. The precise order in which they were arranged is unknown. Between the two divisions was a broad open space called *principia*, where the tribunal of the general was erected when he either administered justice or harangued the army, where punishments were inflicted, and the principal standards, with the altars and images of the gods, were placed. The middle of the lower division was assigned to the Roman horse; next to them were quartered the *triarii;* then the *principes;* and close by them the *hastati*. The companies of foreign horse and foot were posted on the flanks, and carefully kept apart, to obviate the danger of a treacherous coalition. The Roman camp had four gates, and was surrounded by a rampart termed *vallum*, and a ditch, *fossa*. The *agger* or mound of earth was secured by *sudes* or sharp wooden stakes. The camps were sometimes surrounded by walls built of hewn stone; and the soldiers' quarters were occasionally formed of the same materials.

CAMPAGNA, a town of Naples, in the province of Principato Citra, 19 miles east of Salerno. It stands in the centre of a mountainous district, of which it is the capital. It is the see of a bishop, and contains a cathedral and college, besides several churches and convents. Pop. 6700.

CAMPAGNA DI ROMA, the name of an extensive undulating plain which surrounds Rome, coinciding very nearly with the ancient province of Latium. It is bounded N.W.

and N. by the Tiber and Teverone; E. by a branch of the Apennines; S. and S.W. by the Mediterranean; and contains an area of about 2400 square miles, with a population which varies according to the season of the year from about 15,000 to about 275,000. Its greatest length is about 65 miles, its greatest breadth about 45. The most elevated and salubrious districts are in the north and east, embracing the slopes of the Apennines, which are watered by the Teverone and Saccho. Towards the coast the soil is flat, and covered with vegetation only in winter and the early part of spring. In summer it is parched and bare; and would be entirely deserted but for the few farm-servants who at night retire for shelter to the towns, and the hardy peasants from the neighbouring hills who for a trifling remuneration expose themselves to the malaria and vapours which prevail at harvest-time. Many of these soon fall victims to the malaria fever, and in the end of autumn the hospitals at Rome are filled with others. The proprietors of the farms for the most part reside in the capital; and on the approach of summer the herdsmen, turning loose their horses, drive the sheep and oxen to the pastures of the Apennines. The most pestilential district is that in the south, which lies between the Lepini hills and the sea, including the swamps commonly known as the Pomptine marshes. Part of this tract is under cultivation, and a considerable portion was drained by Pius VI., but without much effect so far as the salubrity of the district is concerned. The Campagna is studded with the ruins of ancient Roman villas, and the remains of the aqueducts which supplied the city with water form a very striking feature in the landscape.

The Campagna is divided for judicial purposes between the Comarca di Roma and the delegation of Frosinone.

CAMPAIGN, the space of time during which an army keeps the field. See War.

CAMPAN, a small town of France, department of Hautes Pyrénées, arrondissement of Bagnères-en-Bigorres. It is pleasantly situated in a fine valley on the left bank of the Adour, 16 miles S.S.E. of Tarbes. The town is well laid out, and the houses, which are neat and clean, are mostly built of marble from the neighbouring quarries. Pop. 3500.

Campan, *Madame* (*née* Genet), was married to M. Campan in 1770, soon after which she was appointed first lady of the bed-chamber to the dauphiness Marie Antoinette. She remained at court until the revolution, but was not permitted to accompany her unfortunate mistress to prison. She then supported herself by setting up a boarding school at Germain-en-laye. When Napoleon, in 1806, founded the establishment for the daughters and families of members of the Legion of Honour, the elegant manners and character of Madame Campan pointed her out as a fit superintendent of that institution, an office which she filled with credit to herself, till the overthrow of the emperor and the restoration of the Bourbons caused the suppression of the establishment at Ecouen. Madame Campan then retired to Mantes, where she wrote a very agreeable book, "Memoires sur la Vie Privée de Marie Antoinette Reine de France." It was published some time before the death of the author, which happened in 1822.

CAMPANA, a town of Spain, in the province of Seville, on a small tributary of the Guadalquivir. It contains about 1000 houses, a parish church, several monasteries, and five schools. It has a considerable commerce in the agricultural produce and cattle of the surrounding districts. The flour-mills, oil-mills, wine-presses, and coarse-linen factories, employ the greater part of the inhabitants. Pop. 5380.

CAMPANELLA, Thomas, was born at Stilo, a village of Calabria, in 1568. His progress in languages at school was so rapid, that his father was induced to send him to Naples to study law; but of his own accord he joined the order of Dominicans, and applied to the study of theology. He first signalized himself in the disputes which then raged between the Dominicans and Franciscans; but soon following in the wake of Cardan and Telesius, whose book he publicly defended at Naples, he began to question, and then discarded the authority of Aristotle, although not till after he had mastered the entire circle of Greek, Latin, and Arabian commentators. After a careful study of all the previous systems of philosophy, he published his *Philosophia sensibus demonstrata*; and from the novelty of his opinions he made so many enemies, that he had to take refuge successively in Rome, Florence, Venice, Padua, and Bologna. On account of his supposed connection with a conspiracy then organized in Calabria against the Spanish government, he was seized at Venice, carried to Spain, and imprisoned. He remained in confinement till the death of Philip III., when, at the intercession of Pope Urban VIII., he was transferred to the prison of the Inquisition at Rome, and finally liberated in 1629. It was during his incarceration in Spain that he wrote his *Atheismus triumphatus*, and his *Apologia pro Galilæo*. To escape the machinations of the Spaniards against him, he retired to France; and by the efforts of Cardinal Richelieu he obtained a pension of 2000 livres from Louis XIII. After visiting Descartes in Holland, he attached himself to a Dominican convent at Paris, where he died in 1639. Campanella was the contemporary of Bacon, and like him attempted to deduce all knowledge from nature and experience. He held the only two sources of knowledge to be revelation and nature, and from these endeavoured to construct a new system of theology, metaphysics, ethics, and political economy, in opposition to the prevailing schools of Aristotle and Machiavelli. With Bacon he also attempted a new classification of the sciences.

Besides those already mentioned, his principal works are:—*Philosophiæ rationalis et realis partes V.*, 4to, Paris, 1638; *Civitas Solis*, 12mo, Utrecht, 1643; *Ad doctorem gentium de gentilismo non retinendo, et de prædestinatione et gratiâ*, 4to, Paris, 1656; *De sensu rerum et magia*, 4to, Paris, 1637; *De prædestinatione, electione, reprobatione, et auxiliis divinæ gratiæ, contra Thomisticos*, 4to, Paris, 1636; *Universalis philosophiæ seu metaphysicarum rerum juxta propria dogmata, partes tres, libri XVIII.*, fol., Paris, 1637; *De monarchia Hispanica discursus*, 24mo, Amsterdam, 1640; *Scelta d'alcune poesie filosofice*, Franf. 1622, under the pseudonyme of *Settimontano Squilla*, &c., &c.

CAMPANIA, that part of ancient Italy of which Capua was the chief city. It was bounded by Latium on the north, Samnium on the east, Lucania on the south, and the Mare Inferum on the west. It was anciently celebrated for its fertility and delicious climate; and it constitutes the *Campania Felice* or *Terra di Lavoro* of the modern kingdom of Naples, on both sides of the capital. The ancient Campania, besides Capua and Neapolis, could boast of the flourishing cities of Nuceria, Nola, Pompeii, Herculaneum, Stabiæ, Baiæ, and Salernum.

CAMPANI-ALIMENIS, Matteo, an Italian mechanician and natural philosopher of the seventeenth century. He was born at Spoletto, and held a curacy at Rome in 1661, but devoted himself principally to scientific pursuits. As an optician, he is chiefly celebrated for the manufacture of the large object glasses with which Cassini discovered two of Saturn's satellites, and for an attempt to rectify chromatic aberration; and in clock-making, for his invention of the illuminated dial-plate, as well as for an attempt to correct the irregularities of the pendulum, arising from variations of temperature. Campani published in 1678 a work on horology, and on the manufacture of lenses for telescopes. His younger brother Giuseppe was also an ingenious optician.

CAMPANIFORM, or Campanulated, *bell-shaped*; a term applied to flowers.

CAMPANILE (Ital. *campána*, a bell), a tower for a bell or bells, either attached to some building, or an independent

structure, as seen in many of the cities of Italy. The campanile of Cremona, the loftiest of these towers, is 396 feet in height.

CAMPANINI, an Italian marble dug at Carrara; so named from its sonorousness when struck.

CAMPBELL, ARCHIBALD, Earl and Marquis of Argyll, was the son of Archibald Earl of Argyll and Lady Anne Douglas daughter of William Earl of Morton. He was born in the year 1598, and educated in the principles of the Reformed religion, of which his ancestors had been zealous promoters. When his father, however, renounced Protestantism and declared himself a Papist, the young earl was put in possesson of his patrimonial estates by order of government, and quickly promoted to places of trust and power. From the commencement of his political career he espoused the cause of the Presbyterian party, and defended the Covenanters when summoned to London to give his opinion of their proceedings before the king. In 1638 he remained with the General Assembly after it had been dissolved by the king's commissioner, and with the other nobility and gentry signed the Solemn League and Covenant in defence of the national liberties. Having thus openly committed himself to the Presbyterian cause, he took a prominent part in the various civil and military transactions of the following years. (See BRITAIN, p. 395, *et seq.*) Having gone to London in the year 1660, he was arrested and thrown into prison. In the following year he was tried for high treason, and, principally on ground of treasonable correspondence with Monk expressing concurrence with his government, he was condemned to death and executed on the 25th of May. He took a cheerful leave of his friends before ascending the scaffold, saying, "I could die like a Roman, but choose rather to die as a Christian;" and kneeling down, he received the fatal blow with the greatest calmness.

CAMPBELL, *Archibald*, Earl of Argyll, son of the preceding, from his youth distinguished himself by his loyalty and attachment to the royal family. Though his father headed the Covenanters, he openly declared his aversion to their cause, and attached himself to the interests of the king. Under Middleton he continued to harass the victorious English, till he received express orders from that general to accept of a capitulation. On the establishment of the commonwealth he was committed to prison, and jealously watched till the restoration, when the king remitted to him his father's forfeiture, and created him Earl of Argyll.

He continued in high esteem with the king and court till the passing of the Test Act in 1681, when, by opposing the exemption from the oath granted in favour of princes of the blood, he had the misfortune to draw down on himself the indignation of the Duke of York.

When called to take the test, Argyll refused, except with the explanation, which he believed to have been approved by the duke, to the effect that he took it only so far as it was consistent with itself and the Protestant religion. The duke accepted the qualification, and Argyll was admitted to sit in council; but a few days afterwards was committed to prison, and indicted for high treason. On being tried, three judges did not scruple to convict him of treason and leasing-making; a jury of fifteen noblemen gave a verdict against him; and the king ordered sentence to be pronounced, but the execution of it suspended till further orders. Argyll, however, seeing no reason to trust to the justice or mercy of his enemies, made his escape from prison, and concealed himself for some time in London. All the rest of his sentence was rigorously executed; his estate was confiscated, and his arms were reversed and torn down. Having escaped to Holland, he remained there during the remaining part of the reign of Charles II. Thinking that the interval before the coronation of James II. presented a favourable opportunity for recovering the constitution by force of arms, he concerted measures with the Duke of Monmouth, and returned to Scotland to command the forces already raised for the purpose; but after a few unsuccessful skirmishes he was taken prisoner and carried to Edinburgh, where he was beheaded on his former sentence, June 30, 1685. At the place of execution he made a short speech; and, after solemnly declaring that he forgave all his enemies, submitted to death with heroic firmness. See BRITAIN.

CAMPBELL, *Archibald*, first Duke of Argyll, son of the preceding, was an active promoter of the revolution. He came over with the Prince of Orange, and was admitted into the convention as Earl of Argyll, though his father's attainder had not been reversed. Having been deputed, along with Sir James Montgomery and Sir John Dalrymple, to present the crown in name of the Scottish Convention to the Prince of Orange, and to tender to him the coronation oath, he was admitted a member of the privy-council, and in 1690 made one of the lords of the treasury. In 1701 he was created Duke of Argyll. He married Elizabeth, daughter of Sir Lionel Talmash of Helmingham in the county of Suffolk, by whom he left issue two sons and a daughter.

CAMPBELL, *John*, second Duke of Argyll, and also Duke of Greenwich and Baron of Chatham, son of the preceding, was born on the 10th of October 1680. On perceiving his military talents, his father in 1701 introduced him to King William, and procured his appointment to the command of a regiment. In this situation he remained till the death of his father in 1703, when, becoming Duke of Argyll, he was appointed a member of Queen Anne's privy-council, and at the same time captain of the Scotch horse guards, and one of the extraordinary lords of session. In 1704 he was installed one of the knights of the recently revived order of the Thistle, and soon afterwards appointed high commissioner to the Scotch parliament. In return for his services in promoting the Union, he was created a peer of England, by the titles of Baron of Chatham and Earl of Greenwich; and in 1710 was made a knight of the Garter. His grace first distinguished himself in a military capacity at the battle of Oudenarde, where he commanded as brigadier-general; and was afterwards present under the Duke of Marlborough at the sieges of Lisle, Ghent, Bruges, and Tournay. He had also a considerable share in the victory obtained over the French at the battle of Malplaquet, by dislodging them from the wood of Sart, and gaining a post of great consequence. In this sharp engagement several musket-balls passed through the duke's clothes, hat, and peruke. Soon after the action he was sent to take the command in Spain; but being seized with a violent fever at Barcelona, and disappointed of supplies from home, he returned to England. Having a seat in the House of Lords, he censured the measures of the ministry with such freedom that all his places were disposed of to other noblemen; but at the accession of George I. he recovered his influence. On the breaking out of the rebellion in 1715 he was appointed commander-in-chief of the forces in North Britain, and was principally instrumental in effecting the total extinction of the rebellion in Scotland, without much bloodshed. He arrived in London early in March 1716, and at first stood high in the favour of the king; but in a few months was stripped of his offices. This disgrace, however, did not deter him from the discharge of his parliamentary duties; he supported the bill for the impeachment of Bishop Atterbury, and lent his aid to his countrymen by opposing the bill for punishing the city of Edinburgh for the Porteous riot. In the beginning of the year 1719 he was again admitted into favour, appointed lord-steward of the household, and in April following created Duke of Greenwich. He continued in the administration during the remaining part of that reign, and, after the accession of George II., till April 1740, when, on occasion of

a violent speech against the government, he was again dismissed from office. On a change of the ministry, however, he was soon restored; but disapproving of the measures of the new administration, he finally resigned all his posts, and spent the rest of his life in privacy and retirement. He died of a paralytic disorder on the 4th of October 1743. A monument, executed by Roubillac, has been erected to his memory in Westminster Abbey. See Britain.

Campbell, *Archibald*, third Duke of Argyll, brother of the preceding, was born at Hamhouse in England, in June 1682, and was educated at the university of Glasgow. He afterwards studied civil law at Utrecht; but, upon his father being created a duke, he betook himself to a military life, and served for a short time under the Duke of Marlborough. In 1705 he was appointed treasurer of Scotland, and in the following year was one of the commissioners for treating of the Union; on the consummation of which, he was chosen one of the sixteen peers for Scotland in the first parliament of Great Britain. In 1711 he was called to the privy-council; and when the rebellion broke out in 1715, he took up arms in defence of the house of Hanover, and received a wound at the battle of Sheriffmuir. He was appointed keeper of the privy seal in 1725, and afterwards intrusted with the principal management of Scottish affairs. It was by his advice that, after the rebellion in 1745, the Highlanders were employed in the royal army. In 1734 he was made keeper of the great seal, an office which he held till his death. The duke was eminent not only for his political abilities, but for his literary accomplishments, and had collected one of the most valuable private libraries in Great Britain. He died suddenly on the 15th of April 1761, in the seventy-ninth year of his age.

Campbell, *George*, D.D., a distinguished theologian and philosopher, was born at Aberdeen, December 25, 1719. He was educated at the grammar-school of his native place; but being designed by his friends for the legal profession, he was immediately after removed to Edinburgh, and apprenticed to a writer to the signet. Long before the term of his apprenticeship had expired, he had been in the habit of attending the divinity lectures at the university; and when he had fulfilled his engagement, he enrolled himself as a regular student in the divinity hall at Aberdeen, attending the lectures at both colleges. Having received license from the presbytery of that city in 1746, he was two years later presented to the living of Banchory-Ternan, where he continued to labour till 1757. From Banchory-Ternan he was translated to Aberdeen, and soon afterwards appointed Principal of Marischal college. In 1763 he published his well-known *Dissertation* in answer to Hume's *Treatise on Miracles*, a work which procured for him the respect of his antagonist, and still ranks as a valuable contribution to the literature of apologetic theology. On being elected professor of divinity in Marischal college he resigned his ministerial charge in the city, and devoted himself entirely to his professorial duties. In 1771 he published a *Sermon on the Spirit of the Gospel;* and five years later, the *Philosophy of Rhetoric*, part of which was written at Banchory-Ternan. In the discussion of the leading political questions of the day, Principal Campbell took a prominent part. In his sermon on the Duty of Allegiance he severely condemned the American revolutionary war; and still later he rendered himself peculiarly unpopular by his zealous advocacy of the Catholic Emancipation bill, in an *Address to the People of Scotland* on that subject. The last of his works which he lived to complete was a *Translation of the Four Gospels, with Dissertations and Notes*, which is valuable as one of the few native contributions to exegetical science. He was compelled by the state of his health to resign his professorship in 1795, on which occasion he received a pension of L.300 a-year from the government. In the following year he died of a paroxysm of palsy in the 77th year of his age. His *Lectures on Ecclesiastical History* were published after his death. These consist entirely of the prelections which he had delivered to the students on that subject.

Campbell, *John*, LL.D., a voluminous historical, biographical, and political writer, was born at Edinburgh, March 8, 1708. His father was Robert Campbell, Esq. of Glenlyon, and his mother, Elizabeth, daughter of Mr Smith of Windsor, was a descendant of the poet Waller. Having been designed by his father for the legal profession, he was sent to Windsor, and apprenticed to an attorney; but his tastes soon after led him to abandon the study of law, and to devote himself entirely to literature. In 1736 he published the *Military History of Prince Eugene and the Duke of Marlborough*, and soon after contributed several important articles to the *Ancient Universal History*. This was succeeded, in 1742 and 1744, by the *Lives of the British Admirals*, &c., in 4 vols., a work that was highly popular when it appeared, and which has received continuations from the pens of Dr Berkenhout, Redhead York, and Stephens. Besides contributing to the *Biographia Britannica*, and Dodsley's *Preceptor*, he published a work on *The Present State of Europe*, consisting of a series of papers which had appeared in the *Museum*. He also wrote the histories of the Portuguese, Dutch, Spanish, French, Swedish, Danish, and Ostend settlements in the East Indies, and the histories of Spain, Portugal, Algarve, Navarre, and France, from the time of Clovis till 1656, for the *Modern Universal History*. At the request of Lord Bute, he published a vindication of the Peace of Paris concluded in 1763, embodying in it a descriptive and historical account of the New Sugar Islands in the West Indies. By the king he was appointed agent for the provinces of Georgia in 1755. His last and most elaborate work, *Political Survey of Britain*, 2 vols., 4to, was published in 1744, and greatly increased the author's reputation, though now it is almost entirely superseded by later authorities. Dr Campbell died December 28, 1775. During his lifetime he enjoyed a European reputation for the extent and accuracy of his scholarship, the simplicity of his life, and the amiability of his disposition. He received the honorary degree of LL.D. from the university of Glasgow in 1745.

Campbell, *Thomas* (1777–1844). This distinguished poet was a cadet of the respectable family of Campbell of Kirnan, in Argyllshire. Owing to the straitened circumstances of his father, who had settled in Glasgow and been unfortunate in business, young Campbell was obliged, while attending college, to have recourse to private teaching as a tutor. Notwithstanding the amount of additional labour thus entailed, he made rapid progress in his studies, and attained considerable distinction at the university over which it was his fortune, in after years, to preside. He very early gave proofs of his aptitude for literary composition, especially in the department of poetry; and so strong was his addiction to these pursuits, that he could not bring himself seriously to adopt the choice of a profession. From private tuition, which is at best an irksome drudgery, he recoiled after a short trial. Neither law, physic, nor divinity, had any attractions for him; nor is it probable that he ever would have risen to eminence in a regular profession, owing to a constitutional sensitiveness almost morbid, and a want of resolute energy. We are told by his friend and biographer Dr Beattie, that "the imaginative faculty had been so unremittingly cultivated, that circumstances, trifling in themselves, had acquired undue influence over his mind, and been rendered formidable by an exaggeration of which he was at the moment unconscious. Hence various difficulties, which industry might have overcome, assumed to his eye the appearance of insurmountable obstacles. Without resolution to persevere, or philosophy to submit to the force

of necessity, he drew from everything around him, with morbid ingenuity, some melancholy presage of the future. He was dissatisfied with himself, chilled by the world's neglect, and greatly hurt by the apathy of friends who had extolled his merits, but left him to pine in obscurity." Campbell was not a man who could have successfully struggled with the world. Fortunately for him, his genius was such as to ensure an early recognition.

We find him at the age of twenty in Edinburgh, attending lectures at the university, soliciting employment from the booksellers, and not unknown to a circle of young men then resident in the Scottish metropolis, whose names have become historical. Among these were Walter Scott, Henry Brougham, Francis Jeffrey, Dr Thomas Brown, John Leyden, and James Grahame, the author of the *Sabbath*. He also became acquainted with the late Dr Robert Anderson, editor of a collection of the British poets, a man of extreme enthusiasm and kindliness of disposition, who early appreciated the remarkable powers of Campbell, and encouraged him to proceed in his literary career. In 1799 his poem *The Pleasures of Hope* was published.

Probably there is no parallel instance of literary success so instantaneously achieved by a first effort; nor was that owing to novelty of design on the part of the author, or the caprice of the public. For more than half a century the poem has maintained, nay, increased its popularity. During that time the public has adopted and abandoned many favourites—names once famous and in every mouth, have gradually become forgotten and unregarded—poetical works of greater pretension, which were once considered as master-pieces of genius and inspiration, have fallen into neglect; but this poem by the boy Campbell remains a universal favourite. It is not too much to say that it is, without any exception, the finest didactic poem in the English language. Even those who are not admirers of didactic poetry are forced to admit its charm; and the uttermost objection that criticism can make appears to be a certain vagueness, which, after all, is inseparable from the nature of the subject, and the necessary plan of the composition. The delicacy of the thoughts, the beauty of the imagery, the occasional power of pathos, the extraordinary felicity of the language, and the wonderful harmony of the versification, distinguish the *Pleasures of Hope* from any poem which has been written before or since, and entitle it to a very high place as an original work of genius. It is as original, and characteristic of its author, as is the *Deserted Village* of Goldsmith, with which it has been frequently, but surely improperly compared. Goldsmith's poem affects us by its simplicity and truth. Campbell's, it must be owned, is much more florid and ornamented; but how exquisite is the taste of the ornament!

The literary and the private histories of an author are inseparable. In order to comprehend the one we must have recourse to the other. The first success of Campbell brought him fame, but not fortune. He had disposed of the copyright of the *Pleasures of Hope*, by his original bargain with the publishers, for a sum certainly moderate, which, however, probably exceeded his expectations at the time. He was, moreover, very kindly treated, for he received a considerable unstipulated allowance for each new edition, which circumstance ought to have deterred him from uttering certain diatribes against "the trade," in which he was afterwards rather prone to indulge. The fact is that he did not know how to make use of his success. Instead of availing himself of the reputation which he had so worthily and decisively won, and applying himself to a new effort, he went abroad without any determinate aim; was perfectly wretched on the Continent, where he had no friends, and was sorely embarrassed for want of means; and began to write fugitive poetry for the London journals. On his return to Britain he had ample opportunity of bettering his condition. With a name such as his, a moderate amount of exertion would have secured him not only a competency but comparative affluence; but indolence, perhaps the result of timidity, had grown upon him. Campbell never could adapt himself even to the profession of literature, which, precarious though it be, is not without its prizes. In that profession, as in all others, the requisites for success are steadiness, punctuality, and perseverance; but Campbell possessed none of them. The publishers were ready, and offered to give him lucrative employment, nor was he at all backward in accepting their offers; but when the period for performance arrived he had literally done nothing. In extraordinary contrast to him stands Scott, who seemed simply to will in order to conceive and execute. Campbell had many bright conceptions, but he could not apply himself to the work. Of course he lost repute with the men who alone can intervene between an author and the public, and "the fathers of the Row" became chary of offering him engagements. Some idea of the extent of his habitual indolence may be formed from the fact, that the publication of his *Specimens of the British Poets* did not take place until thirteen years after the work was undertaken!

In the meantime Campbell married; and his prospects were of the darkest, when, in 1805, he received a government pension of L.200. He was then in great distress, and even that aid, material as it was, failed to extricate him. It was probably fortunate for his fame that such was the case, for in 1809 he published his poem of *Gertrude of Wyoming*, to which were attached the most celebrated of his grand and powerful lyrics.

Among Campbell's lengthier poems, *Gertrude of Wyoming* must hold the second place. He designed it for a poem of action, but he has failed to give it that interest and vivacity which a poem of action requires. There is in it too decided a predominance of the sentimental vein, and an extreme degree of elaboration, which, in poetry as in painting, is hurtful to the general effect. There is great truth in the following criticism, which occurs in a letter from Jeffrey to the author: "Your timidity or fastidiousness, or some other knavish quality, will not let you give your conceptions glowing, and bold, and powerful, as they present themselves; but you must chasten, and refine, and soften them, forsooth, till half their nature and grandeur is chiselled away from them. Believe me, the world will never know how truly you are a great and original poet till you venture to cast before it some of the rough pearls of your fancy." In spite of these defects, *Gertrude* was considered at the time as a work in every way worthy of the poet's previous reputation; and it will ever be admired by that numerous class of readers who are more fascinated by the beauties of expression than by high inventive power and vigorous execution.

The soundness of the above criticism, proceeding from an eminent literary authority whose own leanings were rather towards than against fastidiousness in composition, is demonstrated by the universal admiration accorded to Campbell's lyrical pieces. One or two of these, in particular *Lochiel's Warning* and *Hohenlinden*, are to be referred to an earlier period than the composition of *Gertrude;* but there are others of a later date which show how much power remained in the man when he chose to exert it freely. There are few lyrics in the English language to be placed in comparison with the *Mariners of England* or *The Battle of the Baltic;* and his exquisite poem of *O'Connor's Child*, which has not unaptly been termed the diamond of his casket of gems, is greatly superior in pathos and passion to his more elaborate compositions. All these, and others scarcely inferior to them, seem to have been struck off at a heat, and to have escaped that chiselling process to which Jeffrey so pointedly referred.

Campbell was now settled at Sydenham in England, and

his circumstances were materially improved. His home was a happy one; the society in which he moved was of the most refined and intellectual character; and he enjoyed the personal friendship of many of his distinguished contemporaries. Ample leisure was afforded him to carry into effect any of the cherished schemes of his literary ambition; but his indolence and inherent want of resolution again interfered. His most note-worthy exertion for years appears to have been the preparation of a short course of lectures on poetry, which he delivered with great *eclat* at the Royal Institution in London, and elsewhere. It appears that at one time it was proposed by his friends, and especially by Sir Walter Scott, that he should become a candidate for the occupancy of a literary chair in the University of Edinburgh; but he shrunk from the idea of undertaking so serious a labour as is involved in the preparation of a thorough academical course. In 1820 he accepted the editorship of the *New Monthly Magazine*, and acted in that capacity for a considerable period, until he resigned it to take charge of the *Metropolitan*. His connection with periodical literature may have been advantageous in a pecuniary point of view, but did not tend materially to enhance his reputation. His was not the pen of the ready writer; and it must ever be regretted that he was induced to bestow so much attention upon merely ephemeral literature, to the sacrifice of the nobler aims which were expected from his acknowledged genius. In 1824 he published his *Theodric*, a poem which, in spite of some fine passages, was generally considered as a failure. With *Theodric* his poetical career may be said to have closed. At times he put forth short poems of various degrees of merit, but none of them were equal to the grand lyrics already treasured in the memory of his countrymen. It seemed as if a large portion of the old virtue had departed from him; and his last published poem, the *Pilgrim of Glencoe*, showed hardly any marks of his former accomplishment and power.

In fact it appeared that the rich mine of poetry had been worked out. Without actually adopting that conclusion, we may observe that Campbell had latterly occupied himself most zealously with matters which were apart from his earlier pursuits. In the first place he took an active share in the institution of the London University, and it was mainly through his exertions that it was saved from becoming a mere sectarian college. Shortly afterwards, in 1826, he was elected Lord Rector of the University of Glasgow, an event which he considered as the crowning honour of his life, and which certainly was a mark of distinction of which any man might have been proud. He did not accept the office as a mere sinecure, but applied himself to discharge the actual duties (which, through the negligence of former rectors, had been allowed to fall into abeyance) with a zeal and energy which made entire conquest of the hearts of his youthful constituents. In 1831, the year in which the gallant struggle of the Poles for their independence was terminated by entire defeat, Campbell, who in his earliest poem had referred in such beautiful language to the shameful partition of Poland, more than revived his youthful enthusiasm for her cause. He had watched with an anxiety almost bordering on fanaticism the progress of the patriotic movement; and the news of the capture of Warsaw by the Russians affected him as if it had been the deepest of personal calamities. "His heart," says his biographer, "was in the subject of Poland; he could neither write nor speak upon any other with common patience; and if a word was dropt in company that did not harmonize with his feelings, he was very apt to consider it as a personal offence." In one of his own letters he says—"I know that my zeal for Poland has put me half mad." And again—"It is still all that I can do to support a tolerable cheerfulness before these kind hospitable people, for Poland preys on my heart night and day. It is sometimes a relief to me to weep in secret, and I do weep long and bitterly." Nor did he show his sympathy by words alone, but by resolute and continued action. He was the founder of the association in London of the Friends of Poland, which not only served to maintain the strong interest felt by the British people for the Polish cause, but was the means of providing assistance and giving employment to large numbers of the unfortunate exiles who were driven to seek refuge in this country. Never, till his dying day, did he relax his exertions in their behalf; and many an unhappy wanderer, who, but for unexpected aid, might have perished in the streets of a foreign city, had reason to bless the name of Thomas Campbell.

The remainder of his life presents few features of interest. Domestic calamity had overtaken him. His wife, whom he loved affectionately, had been taken from him—of his two sons, one died in infancy, and the other was afflicted by an incurable malady. His own health became impaired. He gradually withdrew from public life, and died at Boulogne on 15th July 1844, at the age of sixty-seven. His last hours were soothed by the affectionate care of his relatives and friends; nor did his countrymen forget the poet in his death, for his remains were solemnly interred in Westminster Abbey, with the honours of a public funeral.

Few poets of reputation, whose span has been extended nearly to the threescore and ten allotted years, have written so little as Campbell: at the same time it must be confessed that there are fewer still whose works are likely to be prized by posterity in the like proportion with his. If we throw out of consideration altogether *Theodric*—though some might demur to such an excision—if we overlook the *Pilgrim of Glencoe*, and weed from his lyrical garden such plants as have little charm either from their colour or their fragrance, there will still remain a mass of poetry familiar to the ear and the heart, such as hardly any other writer of this century has been able to produce. We may regret that Campbell was not more diligent in the cultivation of his poetical genius—that he did not apply himself more sedulously in his earlier years to some serious effort—and that he allowed other pursuits and designs to interfere with his peculiar calling. But who can venture to say what success might have attended his efforts had he acted otherwise than he did? We blame the poet for apparent indolence, not reflecting that inspiration is not to be commanded at will. It is not only possible but easy for the man who is practised in versification to write a certain given number of lines within a certain specified time; but genuine poetry never was and never will be the product of Egyptian taskwork. It cannot be produced to order—it must be spontaneous; and its quality must depend entirely upon the mood of mind under which it is composed. The greater part of the poetry or rather the verse of Southey, a considerable portion of that of Scott, and a vast deal of that of Wordsworth, was not conceived or written under the poetic impulse. On such occasions these celebrated men were writing verse, as they might have written prose, without enthusiasm or anything like the feeling of passion: and although their ordinary thoughts were far higher, bolder, and more subtle than those of the million, they still were not attempting to rise beyond their ordinary intellectual level. One can see at a glance when they were inspired, and when they were merely versifying. Of the poets who adorned the first half of the present century, Coleridge and Campbell were conspicuous for their abstinence in writing except under the influence of real emotion. Of the former it may be said that he has hardly penned a line of mere mechanical verse—the latter did not do so until his inspiration seemed to have abandoned him. Undoubtedly, however—to have recourse to a hackneyed, though by no means an unmeaning phrase—it is the duty of the poet to woo the muse, not to wait for her courtship. He must seek for the

waters of Castaly, not tarry till they are conveyed to him; and it is in this respect probably that Campbell principally erred. He did not sufficiently endeavour to awake his genius; he was too much a dreamer; and may at times have lost his opportunity from the sheer weight of indolence. And yet, considering the value of the legacy he has left, we have no reason to complain. Critics may dispute regarding the comparative merits of his longer works; and, as they incline towards didactic or narrative poetry, may prefer the one composition to the other. Both are entitled to high praise and honour, but it is on his lyrics that the future reputation of Campbell must principally rest. They have taken their place, never to be disturbed, in the popular heart; and, until the language in which they are written perishes, they are certain to endure. (W. E. A.)

CAMPBELTOWN, a royal burgh and seaport of Scotland, Argyllshire, situated on an indentation of the coast near the southern extremity of the peninsula of Cantyre. The inlet of the sea, which forms an excellent harbour, is about 2 miles in length by 1 in breadth, and has from 6 to 15 fathoms water. The registered vessels belonging to the ports at 31st December 1852, were 21 sailing vessels of 1252 tons, and 2 steam vessels of 259 tons. During that year 752 sailing vessels of 21,512 tons, and 342 steam vessels of 44,619 tons entered; and 341 sailing vessels of 8645 tons, and 339 steam vessels of 43,954 tons left. It is supposed to be a place of considerable antiquity, though no memorial of this exists except a flat stone cross on which are a variety of figures in relief and an inscription, but no date. Popular tradition, however, has assigned it to the twelfth century. It was brought from Icolmkill, and is now elevated on a pedestal in the market-place. Prior to 1700 Campbeltown was a mere fishing village, but was then erected into a royal burgh through the interest of the Argyll family, from whom it derived its name. The parliamentary boundaries are very extensive, including the entire parish, which had in 1851 a pop. of 6880. It unites with Ayr, Irvine, Inverary, and Oban, in returning a member to parliament. The town is governed by a provost and 17 councillors. There are distilleries in the town and neighbourhood, and its whisky is much esteemed. Many of the inhabitants are engaged in the fisheries and coasting trade.

CAMPDEN-CHIPPING, a market-town of England, county of Gloucester, 24 miles N.E. of the town of Gloucester, and 90 miles from London. It is situated in a well-wooded valley, and consists of one long street, with some fine old buildings, among which are the market-house, court-house, grammar-school, which has an exhibition at Pembroke College, Oxford, and a beautiful Gothic church. Pop. of parish (1851) 2351.

CAMPEACHY, or CAMPECHE, a fortified town of Mexico, in the province of Yucatan, is situated on a bay to which it gives name, on the west coast of the peninsula. When first taken by the Spaniards it contained about 3000 houses, and had considerable monuments of Indian art and industry. It has often been stormed and taken by English and French bucaneers, and has also suffered severely from other marauders. The town is generally well-built, the houses being of stone, with some substantial public edifices, including several churches and convents, a theatre, museum, college, &c. The port is large, but shallow. It is the centre of a large trade in log-wood, and exports considerable quantities of wax and cotton. The population of the town amounts to about 9000. W. Long. 90. 31., N. Lat. 19. 51.

CAMPER, PETER, a celebrated naturalist and anatomist, born at Leyden, May 11, 1722. His family had long held distinguished situations in the magistracy of that city. His father, Florent Camper, a Protestant clergyman, was an enthusiastic admirer of painting, and a great patron of artists; and was intimate with several of the learned men who adorned the university of Leyden at that time, especially Boerhaave.

Under circumstances that afforded him so many advantages, young Camper applied himself at an early age to drawing and painting, in which he soon became remarkably proficient.

He was indebted to Laborde for his first lessons in geometry, and was instructed in natural philosophy by Muschenbroeck and Gravesande. At Leyden university he became the pupil of Gaubius, Van Rooyen, and the elder Albinus; and in 1746 he took the degree of doctor in philosophy and medicine, on which occasion he published two dissertations, the one *De Visu*, the other *De Oculi quibusdam Partibus*. In the first he illustrates and defends Smith's *Theory of Vision*, and in the latter describes, with plates, Petit's *Canal in the Eyes of different Animals*.

After the death of his parents, which happened in 1748, Camper visited London, where he made the acquaintance of Mead, Pringle, and Pitcairn. He pursued his medical studies under Hunter, Sharp, Smellie, and Winchester; and diligently examined the cabinets of Hans Sloane and Collinson, and the collections of Hill and Catesby. He studied botany under Elliot, astronomy under Short, and the use of the microscope under Baker. He also directed his attention to the mechanical arts; visiting the principal manufactories, and collecting instructions from artists of eminence in every department, including even naval architecture. He was in the habit of making minutes of everything he saw and learned; and his facility with the pencil enabled him to take sketches of every object of which a delineation could be useful. He still cultivated his taste for painting, and acquired much practical skill in the art of engraving. After remaining about a year in London, and visiting the universities of Oxford and Cambridge, he proceeded to Paris, where he inspected the principal public establishments in that capital. He then proceeded to Lyons and Geneva, when having received intelligence of his being appointed professor in philosophy, medicine, and surgery, at Franeker, he returned to Holland by Switzerland and the banks of the Rhine, visiting as he passed through Basle the great Bernouilli, and examining in the library of that city the writings of Erasmus and the paintings of Holbein. The itinerary which he kept of his journey contains a great number of valuable remarks on agriculture and geology, and shows how well he was gifted with the talent for observation.

In consequence of a severe illness he was obliged to defer entering upon the duties of his professorship till the autumn of 1750. On this occasion he pronounced a public inaugural discourse, *De Mundo Optimo*. About the same period he was elected a fellow of the Royal Society of London.

He again visited England in 1752, and resumed his favourite pursuits with unabated ardour. Among other objects, his attention was much directed to the method of inoculating for the smallpox, the practice of which was as yet confined to England. On his return to Franeker he resumed his lectures, and gained such increasing celebrity that he was soon ranked as one of the ablest men of science in Holland. In 1755 he was appointed professor of anatomy and surgery at the Athenæum of Amsterdam, and settled in that city. According to custom, he pronounced two inaugural discourses, the first, *De Anatomes in omnibus Scientiis usu;* and the second, *De Certo in Medicina*. In 1756 he married the widow of the burgomaster of Harlingen.

After continuing six years in Amsterdam, he resigned his chair, and retired to his country house at Franeker. His principal work during the time he had held that chair was the first volume of his *Demonstrationes Anatomico-Pathologicæ*, the second volume of which appeared in 1762.

Having, two years afterwards, been elected professor of medicine, surgery, and anatomy, at Groningen, he took up his abode in that city, and at his inauguration as professor

Camper. delivered a discourse *De admirabili analogia inter Stirpes et Animalia*. Under his auspices was established a society for the purpose of conducting experiments in agriculture. To this society Camper was nominated secretary. He bestowed much pains in investigating the nature of an epidemic disorder which prevailed extensively among the cattle of Holland. He made this the subject of several lectures which he read in 1796 to the academy of Groningen; and his proposed method of disarming the disease of its virulence by inoculation appears to have effectually succeeded where adopted. At this period he also made a variety of important discoveries in comparative anatomy.

After ten years spent at Groningen, he was induced to remove to Franeker, that he might superintend the education of his sons, who were to be placed at the academy in that place. In 1776, the death of his wife, in whom his affections had been centred during a union of twenty years, determined him to seek in travel some alleviation of his sorrow. After visiting all the cities that offered objects of attraction in the sciences or the fine arts, he proceeded to Paris, where he enjoyed the society of Franklin, Marmontel, Diderot, Daubenton, Portal, and other distinguished men. Returning to his own country with recruited spirits, he applied himself with fresh ardour to his favourite pursuits; and aiming at more comprehensive views of the animal kingdom, occupied himself in pursuing the analogies which connect its several departments, and in tracing the successive links of that extended chain by which the different orders of beings are united in one continued series of gradation. A tour through Germany, at a later period, made him acquainted with many treasures in natural history, with which that country abounds. The anatomical preparations of Kerkringius, and the observatory of Tycho Brahe at Hamburg, the collections of natural history of Taube and Desrogues at Zell, and the superb cabinet of antiquities of the Count Walmoden at Hanover, particularly attracted his attention; and he explored with the eye of a geologist the volcanic district of Cassel. He formed also the acquaintance of Zimmerman, Soemmerring, and other eminent physicians. The following year he visited Prussia, and was presented to the great Frederick, who received him at Potsdam with much affability and respect; and on his return he had the honour of spending two days with the brother of the king, Prince Henry of Prussia, at Rheinsberg.

In 1785 Camper was chosen member of the Royal Academy of Sciences at Paris; and in the same year he paid a fourth visit to England.

His literary and philosophical occupations did not preclude him from taking an active part in the political concerns of his country. In 1762 he was returned as deputy in the assembly of the province of Friesland; and in 1776 he appeared there as deputy for Idaarderadeel. In 1783, on the recommendation of the stadtholder, he was nominated one of the council of state of the United Provinces, and was of course obliged to reside at the Hague. During the revolution he remained faithfully attached to the party of the stadtholder. Camper died of a violent pleurisy, on the 7th of April 1789; and his remains were deposited in the church of St Peter at Leyden.

To a mind enriched with vast stores of knowledge, and adorned with a taste at once elegant and refined, Camper united the most benevolent affections, and possessed all the virtues of domestic and social life. Nature had bestowed upon him a dignified and graceful form, and a remarkably animated and expressive countenance. He spoke fluently Latin, English, French, and German, and had a competent knowledge of Greek and Italian.

Besides the honorary distinctions already mentioned, Camper was member of the academies of Petersburg, Berlin, Edinburgh, Manchester, Toulouse, Göttingen, Haarlem, Rotterdam, and Flushing; and was foreign associate of the Royal Society of Medicine at Paris. He obtained the prize of the academy of Haarlem for his *Memoir on the Physical Education of Children*. His *Researches on Specific Remedies* gained him the prize of the Academy of Sciences of Dijon; his *Observations on Inoculation* that of the Academy of Toulouse; and his *Memoir on Chronic Diseases of the Chest* that of the Academy of Lyons. The Royal Academy of Surgery voted him three prizes for his *Memoirs on the Influence of Different Circumstances in Regimen on the Treatment of Surgical Diseases*. Of Camper's numerous works, the most important only can be noticed here. His principal labours were bestowed on comparative anatomy and physiology, and his discoveries in this wide field of research are numerous and important. A posthumous collection of his works on these subjects appeared at Paris in 1803, in 3 vols. 8vo, with a folio atlas of plates, under the title of *Œuvres de Pierre Camper, qui ont pour objet l'Histoire Naturelle, la Physiologie, et l'Anatomie Comparée;* to which is prefixed an Essay on his Life and Writings by his son, and two eulogiums, one by Vicq d'Azyr, and the other by Condorcet. They contain his *Dissection and Natural History of the Orang-outang, and other Species of Apes*. He examines especially the peculiarities in the structure of the organ of voice of those animals, which deprive them of the power of uttering articulate sounds, and which alone would place an immense interval between them and the human species. His anatomical description of the two-horned rhinoceros, of the rein-deer, and of the elephant, are the subjects of separate dissertations; as also his researches on the structure of the great bones of birds, and the manner in which atmospherical air is introduced into them (a fact which was discovered by Camper prior to the time at which Hunter published his observations on it); on the structure of the porpoise and the whale; on the classification of fishes according to the system of Linnæus; on the anatomical structure of the organs of hearing in fishes, and of the blowing-holes of the *cetacea;* on the *dugon* of Buffon, and the *sirena lacertina* of Linnæus, both of which he pronounces to belong to the class of fishes; on the generation of the *pipa* or American toad; on the croaking of the male frog; on the petrifactions found in the mountain of St Peter near Maestricht, and the fossil bones of fish and other animals; on the analogies that may be traced between the several parts of the animal kingdom, especially in the structure of the human species compared with those of quadrupeds, birds, and fishes; on the alteration of form in the human species produced by age; on the diversity of features which characterize different nations, and the mode of expressing these differences in delineating the human figure; on the mode in which the passions are indicated by the countenance; on the *beau physique*, or the beauty of forms; and on the analogy between plants and animals. In the practical branches of medicine he has written observations on the inoculation of the smallpox, founded on experiment; on the theory and treatment of chronic diseases of the lungs, and a historical inquiry into the principal methods of cure employed by the ancients and moderns in these disorders; on the nature, employment, and mode of operation of remedies termed specifics; on the nature, causes, and treatment of dropsy, and the different indications of cure derived from the symptoms; on the nature of cancer, and on the signs denoting those of the breast that do not admit of cure; on the herniæ incident to new-born children, &c.; on ulcers in the urethra and prolapsus ani; on the fracture of the patella; on the callus of fractured bones; on lithotomy, and especially on the method of performing that operation at two different times, according to the plan of the celebrated Franco; on the construction of bandages for herniæ; on bandages in general; on the abuse of ointments and plasters in the treatment of ulcers, and on improved methods of managing them; on the noxious effects attending the admission of air into the body, and the influence of this principle on the treatment of surgical diseases. In the department of midwifery he has written a letter to Dr Van Gescher on the utility of the section of the *symphysis pubis* in severe labours, and observations on the use of the lever of Roonhuysen in difficult parturition. Several memoirs on the subject of infanticide, and the juridical questions connected with that subject, were published by him at Leeuwarden. (P. M. R.)

Camperdown ‖ Camphor.

CAMPERDOWN, a village of Holland, province of North Holland, 27 miles N.W. of Amsterdam. Off this place Admiral Duncan gained a great naval victory over the Dutch under Admiral de Winter, Oct. 11, 1797.

CAMPHOR, a concrete essential oil, or *stearoptine*, obtained from vegetables. Two kinds are known in commerce. The well-known common camphor is obtained in the East by the distillation of the roots and branches of the *Laurus camphora*. Small quantities of it are found in the wood of the tree in a solid state. The second kind was

till lately little known in Europe. It is found in cavities in the stem of a large Bornean forest tree, *Dryobalanops camphora*. This sort has a slightly alliaceous odour mixed with that of camphor, occurs in small grains, and is highly valued by the Chinese, who give for it 100 times the price which they give for ordinary camphor. A tree of full size will yield, it is said, from 11 to 22 pounds avoirdupois of that camphor; but it causes the total destruction of the tree, which does not produce this substance until it has attained a large size. See CHEMISTRY, and *Index*.

CAMPIAN, EDMUND, a celebrated English Jesuit, born of indigent parents at London in 1540. From Christ's Hospital he removed to Oxford University, where he took a degree. He was admitted to holy orders in the English Church, and held the respondency of the philosophical act at St Mary's Church. When at school he had been selected to make an oration before Queen Mary on her accession, and now when at college he did the same before Queen Elizabeth. On leaving college he went to Ireland, where he wrote the history of that country, and joined the Church of Rome. Betraying too great zeal in proselytizing to his new faith, he drew down on himself the suspicions of the government, and was committed to prison; but soon after escaped to the Low Countries, when he settled at Douay, and passed his novitiate as member of the Society of Jesus. After residing for a short time at Brune, Vienna, and Prague, where he taught philosophy and rhetoric, he was sent by Gregory XIII., along with Father Parsons, on a propagandist mission to England. Scarcely had he arrived in England in 1581, and entered on his duties by challenging the universities and clergy to dispute with him, when at the instance of Secretary Walshingham he was apprehended along with Parsons and two other agents at Lyford in Berks, and thrown into the Tower, on a charge of having excited the people to rebellion, and holding treasonable correspondence with the foreign powers. Having been found guilty, he was condemned to death, and executed at Tyburn, Dec. 1, 1581, with several others of his order. He is admitted to have been a man of great abilities, an eloquent orator, a subtle philosopher, and able diplomatist; and he is praised by all writers, whether Protestant or Popish, not only for his talents and acquirements, but likewise for the amiableness of his disposition. Besides the History of Ireland already mentioned, he wrote a *Chronologia Universalis; Conferences at the Tower*, 4to, 1583; *Narratio de Divortio; Orationes; Epistolæ Variæ;* and *De Imitatione Rhetorica.*

CAMPIDOCTORES, officers who drilled the Roman soldiery.

CAMPILLO DE ARENAS, a village in the district of Jaen, Seville, Spain. It was the scene of a battle gained by the French over the Spaniards in 1823. Pop. 1121.

CAMPITÆ, an appellation of the Donatists, from their assembling in the fields. For a similar reason they were sometimes called *Montenses* and *Rupitani.*

CAMPLI, a town of Italy, in the Neapolitan province of Abruzzo-Ulteriore, five miles north of Teramo. It has a cathedral, an abbey, several churches and convents, and 6200 inhabitants.

CAMPOBASSO, a city of Italy, the capital of the province Molise, 53 miles N.N.E. of Naples. It is situated on the ascent of a high mountain, around which it forms a kind of amphitheatre. It is fortified, and contains two churches, with 7660 inhabitants, who are employed chiefly in making cutlery ware. It is in a fertile district, and has a considerable export trade in corn.

CAMPO DE CRIPTANA, a small town in the province of Ciudad Real, New Castile, Spain. Its principal trade is in the agricultural produce of the district, and the coarse woollen stuffs manufactured in the town. Pop. 5230.

CAMPO FORMIO, a town of Italy, in the delegation of Udine, in Austrian Lombardy, containing 1500 inhabitants. Here, on 17th October 1797, peace was concluded between France and Austria.

CAMPOMANES, PEDRO RODRIQUEZ, CONDE DE, a celebrated Spanish statesman and writer, born in the Asturias about 1710. His grand objects seem to have been to stimulate the industry and education of the people of Spain; and while president of the council of Castile, and director of the Royal Academy of History, he was distinguished by forwarding to the utmost those two important objects, which had been sadly neglected for ages by Spanish statesmen. His transcendent abilities, his learning, and patriotic efforts are highly praised by Townsend and other intelligent travellers who visited Spain from 1780 to 1788. From 1788 to 1793 he was president of the council of Castile; but on the accession of Charles IV. he was removed from his office, and retired from public life, regretted by the true friends of his country. His first work was literary, *Antiquidad Maritima de la Republica de Cartago*, with an appendix containing a translation of the *Voyage of Hanno* the Carthaginian, with curious notes. This appeared in a quarto volume in 1756. His principal works are two admirable essays, *Discurso sobre el Fomento de la Industria Popular*, 1774, and *Discurso sobre la Educacion Popular de los Artesanos y su Fomento*, 1775. As a supplement to the last, he published four appendices, each considerably larger than the original essay. The first contains reflections on the origin of the decay of arts and manufactures in Spain during the last century: the second points out the steps necessary for improving the old manufactures, or of reestablishing them, with a curious collection of royal ordinances and rescripts regarding the encouragement of arts and manufactures, and the introduction of foreign raw materials; the third treats of the guild laws of artizans, contrasted with the results of Spanish legislation and municipal ordinances of towns; the fourth contains eight essays of Francisco Martinez de Mata, on national commerce, with some observations adapted to present circumstances. These were all printed at Madrid in 1774 and 1777 in 5 volumes in 8vo, which then corresponded with the size of our 12mo, as appears from a copy which had been presented by the illustrious author, now in the possession of the writer of this article. Count Campomanes died in 1802. (T. S. T.)

CAMPSIE, a village and parish of Scotland, in the county of Stirling, situated on the banks of the Kelvin, 9 miles from Glasgow. Bleaching, printing, and the manufacture of cotton are extensively carried on here. North of the village are the Campsie Falls, a range of hills rising to the height of 1500 feet. Pop. of parish, including Lennoxtown, &c. (1851) 6918. The population of the village and parish amounted in 1821 to 4927; in 1831 to 5109.

CAMPUS, in antiquity, a field or vacant space in a city for shows, combats, exercises, and other uses.

CAMPUS *Mail*, an anniversary assemblage of our ancestors, held on May-day, when they confederated for the defence of the kingdom against its enemies.

CAMPUS *Martius*, a large plain in the suburbs of ancient Rome, lying between the Quirinal and Capitoline Mounts and the Tiber, and so called because it was consecrated to Mars, and set apart for military sports and exercises. Here also the comitia of the centuries were held, and races were run either with chariots or single horses; and here also stood the villa publica, or palace for the reception of ambassadors, who were not permitted to enter the city. The place was also nobly decorated with statues, arches, columns, porticoes, &c. It was included within the city walls by Aurelian.

CAMPUS Sceleratus, a place beyond the walls of ancient Rome, where unchaste vestals were buried alive. (Liv. viii. 15.)

CAMROOP. See ASSAM.

CAMUS, Charles Stephen Louis, a mathematician and mechanician, born at Cressy en Brie, near Meaux, the 25th August 1699, son of Stephen Camus, a surgeon of that town, and Margaret Maillard.

His taste for practical mechanics was very early demonstrated by a singular ingenuity in the construction of a variety of little machines with which he amused himself; and he soon felt so strongly the value of mathematical studies, that he urged his parents to find the means of sending him to a school where he might apply to them. In compliance with his wishes, he was placed, when he was little more than ten years old, at the College de Navarre in Paris; and in two years he acquired knowledge enough to become an instructor of others, and to relieve his friends from all further expense in his education. He was assisted in the pursuit of the higher departments of the mathematics by the celebrated M. Varignon; and he particularly applied himself to civil and military architecture, and to astronomy.

The first result of his studies that was destined for the public eye, was an essay *On the Masts of Ships*, a subject which had been proposed in 1727 as a prize question by the Academy of Sciences. This essay was received with considerable approbation, and was inserted in the second volume of the *Collection of Prize Memoirs*. Shortly after, the author was made an adjunct or sub-associate of the academy, in the department of mechanics.

In 1728 he brought forward a memoir on the *Living Force* of bodies in motion, in which he concludes, from considering the action of springs and other similar powers, that its true measure is the product of the mass into the square of the velocity, as Leibnitz maintained; this product being also proportional to that of the force into the space through which it acts, while the momentum is proportional to the force and the time conjointly. In December 1730 M. Camus was appointed professor of geometry to the Academy of Architecture, and a few years afterwards he became secretary to the same body.

The *Memoirs of the Academy* for 1732 contain a short paper on a *Problem proposed by M. Cramer*, respecting the determination of two curves bearing a particular relation to each other. It was the custom of the age to consider exercises of this sort as trials of strength, to which it was incumbent on all geometricians to submit, for the honour of the countries in which they lived, and of the societies to which they belonged. The author was elevated in 1733 to the rank of an associate of the academy, together with Clairaut, over whom he even obtained some advantage in the ballot.

He communicated to the academy, in the same year, a valuable paper on the *Teeth of Wheels*. La Hire had already laid the foundation of the investigation on its true basis, and had pointed out the use of different epicycloidal curves for the forms of the teeth of wheels in different circumstances; and M. Camus in this essay enters into some further inquiries, particularly with regard to the best proportions for the length of the teeth, and the comparative diameters of the wheels; a discussion for which his intimate acquaintance with the art of the clockmaker made him particularly well qualified. In 1736 he accompanied Maupertuis and Clairaut in the expedition to Lapland, for the measurement of a degree of the meridian; and he was enabled to render them very essential service, not only as a geometrician and an astronomer, but also by his skill in various departments of the mechanical arts, which became particularly valuable in so remote a situation.

M. Camus directed his attention in 1738 to the well known but interesting mechanical phenomenon of a *pistol ball piercing an open door* without causing any very sensible motion in the door, and published a paper on the subject in the *Memoirs of the Academy*. He justly observes, that the effect of any force depends, not only on its magnitude, but also on the time for which it operates; and that though the impulse of the ball must tend to carry the door before it with a force paramount to the resistance which it opposes to the ball, yet the time of the action of this force is too short to produce a sensible effect on the whole mass of the door. In 1739 he presented to the academy two hydraulic memoirs, the one on *Water Buckets*, the other on *Pumps*. In the latter he investigates the diameter of a valve capable of transmitting the greatest quantity of water within a given barrel; a valve which is too large not being at liberty to rise to a sufficient height.

He inserted in the *Memoirs* for 1740 a confutation of a *Mechanical Fallacy*, which has misled many of the enthusiasts who have bewildered themselves in the search of a perpetual motion; demonstrating that when a number of weights are caused to descend, in any imaginable paths, at a greater distance from the centre of a wheel than they ascend, the number of the weights descending at any one time must always be smaller than those of the weights ascending, and in such a proportion as perfectly to compensate for the mechanical advantage apparently gained by the greater distance. In the following year he was received into the number of the academicians in the department of geometry, on occasion of the resignation of M. Fontenelle. He published also, in the *Memoirs* for 1741, an account of a *Gauging Rule* for measuring barrels of different forms, by simple inspection of the logarithmic scales engraved on it, observing only some easy rules for their adjustment, according to the general nature of the solid. In 1746 he presented a report, in conjunction with M. Hellot, on the *Length of the Standard Ell*, which was thought worthy of being inserted in the collection of the academy.

We find among the *Memoirs* for 1747 an essay of M. Camus on the *Tangents of Curves* having several branches crossing each other, which frequently require for their determination the use of fluxions of the higher orders, the first fluxions of the absciss and ordinate vanishing together. M. Saurin had before given a similar solution of the problem, but had not attempted to explain the metaphysical ground upon which the apparent paradox is reconciled to the general principles of the differential method.

M. Camus also assisted in several determinations and reports which were referred at various times to committees of the academy; and particularly in the remeasurement of M. Picard's base from Villejuif to Juvisy, which was performed by eight members, and recorded in the *Memoirs* for 1754.

The latter years of his life were much occupied in various engagements connected with the offices of examiner in the schools of the Royal Engineers and in that of the Artillery, to which he was nominated by the king. He undertook, for the advantage of the students in these schools, the laborious task of reducing into a uniform system a complete course of mathematical study, in which the geometrical method was as much as possible observed, and which is considered as highly creditable to his talents and exertions; it was entitled *Cours des Mathématiques*, 4 vols. 8vo. 14. He also published an *Elementary work on Arithmetic*.

In person M. Camus was tall; his countenance was agreeable; his manners were firm, and occasionally somewhat warm; but he was far from being either morose or vindictive. He was elected a foreign member of the Royal Society of London in January 1764. He married, in 1733, Mademoiselle M. A. M. Fourrier, and had four daughters, the eldest of whom was married to M. Pagin; the others died young. His last illness was supposed to have originated from a cold taken in a professional journey during the hard winter of 1766, and to have been aggravated by affliction for the loss of his surviving daughter. He died a few months after her, on the 4th of May 1768. He left a variety of manuscripts, demonstrative of his habitual dili-

gence and of the extent of his researches; but not deemed of sufficient importance to meet the hazards of posthumous publication. (*Hist. Acad. Par.* 1768, p. 144.) (T. Y.)

CAMUS, *Jean Pierre*, bishop of Bellay, was born at Paris in 1582. He wrote a great number of pious romances adapted to the taste of his time, and other theological works. His definition of politics is remarkakle—*Ars non tam regendi quam fallendi homines*, the art not so much of governing as of deceiving mankind. He was an exemplary prelate, and distinguished for the zeal with which he attacked the abuses of his time. He died in 1652. Moreri has given a large catalogue of his works.

CAMWOOD, a red dyewood imported from Western Africa. See DYEING.

CANA, a town of Galilee, not far from Capernaum, where Christ performed his first miracle by turning water into wine. Cana is not mentioned in the Old Testament. It has been identified with the modern Kefr Kenna, a small village about four miles N.E. from Nazareth, where there are the remains of an ancient Greek church.

CANAAN, son of Ham and grandson of Noah. The transgressions of his father Ham (Gen. ix. 22–27), to which some suppose Canaan to have been in some way a party, gave occasion to Noah to pronounce that doom on the descendants of Canaan which was, perhaps, at that moment made known to him by one of those extemporaneous inspirations with which the patriarchal fathers appear in other instances to have been favoured. That there is no just ground for the conclusion that the descendants of Canaan were cursed as an immediate consequence of the transgression of Ham, is shown by Professor Bush, who in his *Notes on Genesis* has fairly met the difficulties on the subject.

CANAAN, *Land of*, was the ancient name of that portion of Palestine which lay to the west of the Jordan; the part beyond the Jordan eastward being distinguished by the general name of Gilead. Canaan included both those districts known amongst the Greeks and Romans as Philistia and Phœnicia; and was inhabited by the descendants of Canaan, from whom it took its name. From being promised to Abraham and his seed, it was known beforehand to the patriarchs as the Land of Promise; and when it came to be possessed by the Jews, it went successively under the names the Land of Israel, the Land of Judah, and the Holy Land. For their idolatry seven distinct Canaanitish tribes were given over to the Israelites to be annihilated; but some of them seem to have escaped and incorporated themselves with the invaders, while according to tradition others fled and emigrated to the coast of Africa. In St Athanasius's time the Africans still pretended they were descended from the Canaanites; and it is said that the Punic tongue was almost entirely the same with the Canaanitish and Hebrew languages. The colonies which Cadmus carried into Thebes in Bœotia, and his brother Cilix into Cilicia, appear to have sprung from the stock of Canaan; and the isles of Sicily, Sardinia, Malta, Cyprus, Corfu, Majorca and Minorca, Gades, and Ebusus, are also supposed to have been peopled by the Canaanites. Besides those seven nations which were put to the sword, there were other tribes of Canaanitish origin scattered along the coast of Tyre and Sidon, who were not driven out by the children of Israel; and hence this tract seems to have retained the name of Canaan long after those other parts of the country, which were inhabited by the Israelites, had lost that appellation. The Greeks called the tract along the Mediterranean, inhabited by the old Canaanites, Phœnicia; and the more inland parts, inhabited partly by Canaanites and partly by Syrians, Syrophœnicia; and hence the woman said by St Matthew to be a woman of Canaan is said by St Mark to be a Syrophœnician by nation, as she was a Greek by religion and language. See PALESTINE.

CANADA.

THIS extensive tract of country, and most important colony of England, may be described as a great belt of territory stretching from the centre of North America to the shores of Labrador, and from the waters which flow into the Northern Ocean to the parallel of Pennsylvania, in the United States. Its extent from east to west is computed at about 1400 miles, and from north to south at from 200 to 400 miles. Its precise geographical limits are between the parallels of 41. 71. and 50. N. Lat., and between the meridian of 57. 50. and 117. W. Long.[1]

General Description.

Canada, lying diagonally along the frontier of the United States, from N.E. to S.W., and possessing an inland navigation along its entire border, in a series of lakes and rivers unrivalled for extent and grandeur, has, especially of late years, been making such rapid progress, that it promises soon to become, in conjunction with its sister British provinces, a power of first-class importance, commercially and politically. The entire surface of the present territory of Canada, exclusive of its great waters, has been estimated at 196,000,000 acres, or between two and three times the size of Great Britain and Ireland.

This country, formerly divided into two provinces known as Upper and Lower Canada, was in 1841 by an act of the imperial parliament constituted one province with one legislature. Although now united, however, for legislative and other purposes, the country will most probably continue to be viewed and spoken of under its formerly recognised divisions of Upper and Lower Canada.

Canada may be said to comprise one vast valley through which the great river St Lawrence takes its course, issuing from Lake Superior and flowing successively through Lakes Huron, Erie, and Ontario, until it falls into the ocean after a course of 2000 miles. This immense valley is on each side encompassed by different mountain ranges, sometimes nearly approaching the water, and at other times receding into the interior, and thus forming extensive plains, for the most part alluvial, and suitable for nearly every description of produce. The high table-land along the northern boundary of this valley separates the streams which take their rise within it and flow into its basin from those that take their rise in the almost unknown territory beyond, and which fall into Hudson's Bay. The high land along the southern boundary of the valley separates the streams which flow northwards into its basin, from those that have their course southwards towards the Atlantic and Mississippi.

Northern shore of the St Lawrence.

Commencing at the northern shore of the St Lawrence, towards the mouth of that river, where the width is 90 miles, we find one of the walls of this vast valley which constitutes Canada rising boldly in mountainous form, close to the river, and continuing thus to form its rugged bank for upwards

[1] Bouchette's *British Dominions in North America*, Lond. 1832; *Report to the Senate of the United States*, by Israel D. Andrews, United States Consul for Canada, &c. Washington, 1853.

Canada.

of 100 miles. One of the most remarkable of the heights of this northern bank is Cape Tourment, overhanging the very brink of the river, and somewhat preparing the voyager for the still bolder and more magnificent grandeur of Cape Diamond, the Gibraltar of America, which rises to a height of 400 feet, and is crowned by the citadel of Quebec.

City of Quebec.

The city of Quebec, here clinging around the rocky steeps of Cape Diamond, and overlooking one of the most magnificent harbours in the world, is situate on the northern bank of the St Lawrence, and about 400 miles from the mouth of that river. The view from the citadel presents on every side a country with features of peculiar and striking grandeur. Immediately opposite Quebec, the St Lawrence contracts to about half a mile in width, with bold rocky banks on either side. The northern or Cape Diamond side, being much the bolder of the two, commands a view of the wide stretch of table-land extending beyond the southern bank, the vast plains presenting for leagues upon leagues their dark masses of forest, with houses and cultivated fields interspersed, until the distant mountains of the states of Maine and Vermont bound the view. The northern shore presents a wilder and more rugged aspect. From the heights of Cape Diamond, the spectator surveys bold ranges of hills fringing the northern horizon, and forming the boundaries of almost unexplored territories beyond.

About 30 miles below Quebec is Cape Tourment, to which in our upward progress we had traced the rocky northern bank of the river. Here the ridge, taking a direction W.S.W., terminates on the river Ottawa, about 120 miles above its confluence with the St Lawrence, thus extending westward from Cape Tourment along the course of the St Lawrence about 300 miles. The tract of country lying between this ridge and the St Lawrence, which may be estimated at from 15 to 30 miles in breadth, is beautifully picturesque, well watered, level, and fertile. This portion of Canada, stretching along the northern shore of the river, from below Quebec upwards to Montreal, a distance of about 200 miles, and thence along the banks of the beautiful Ottawa may be considered, especially towards its upper and western extremity, one of the choicest parts of the country.

The territory lying beyond this ridge is intersected by another and higher range of mountains, which runs into the interior in a N.W. direction, at the distance of about 200 miles from the other, and forms the watershed beween the tributary streams of the St Lawrence and those that fall into Hudson's Bay. This territory may be said to be only one great wilderness of forest, whose solitudes are as yet unexplored, and only occasionally tracked by wandering hunters.

South shore of the St Lawrence.

Glancing at the south shore of the St Lawrence, a ridge commences nearly 100 miles below Quebec, which, passing upwards in a S.W. direction, opposite that city, at a distance of 30 miles from the river, crosses the boundary line between Canada and the United States, and finally slopes down to the river Hudson. Beyond this ridge, at about the distance of 50 miles, is another and a higher one, which commences at Cape Rozière, the bold headland at the mouth of the St Lawrence, and, running for about 400 miles in a direction nearly parallel with the river and with the other chain, terminates upon the eastern branch of the river Connecticut. This forms the dividing ridge between the tributary streams of the St Lawrence, and those which flow towards the Atlantic Ocean, and separates a portion of Canada from the territory of the United States.

The general character of the country along this south side of the river, from Cape Rozière upwards, to within about 100 miles of Quebec, where the lesser ridge commences, is somewhat rugged and mountainous; but there are many fertile parts near the river which are populous and well cultivated. On the south side of this main ridge, down to the shores of Gaspé and Chaleur Bay, the country is mountainous, but interspersed with level and fertile spots, some of which are under cultivation, especially along the coast, where the inhabitants are principally dependent on the fisheries. The country for 100 miles below Quebec, and extending to the river Chaudière, a few miles above that city, has much of the broken and hilly character which it has further down the river, but with extensive tracts of excellent land.

This portion, as well as for a distance of above 100 miles further down along the banks of the river, is a succession of settlements. Between Quebec and the lower ridge of mountain-land already mentioned, the country presents a fertile plain, broken by a few insulated hills covered with trees to their summits. It is well settled, and a considerable portion of the land cultivated.

Country above Quebec.

The country above Quebec, along the south side of the St Lawrence, to the line 45. of N. Lat. (which is the southern boundary of Lower Canada), may be characterized as one extensive and fertile plain, in parts agreeably broken and undulating. Much of it is covered with populous and prosperous settlements. As it lies contiguous to the United States, and embraces some of the principal points of communication between the two territories, it is at present, and bids fair to continue to be, the most flourishing portion of this lower division of Canada.

City and Island of Montreal.

The city and island of Montreal, situated in Lower Canada, and immediately below the confluence of the river Ottawa with the St Lawrence, may be said to form the chief connecting link between the lower and upper provinces. Being about 180 miles above Quebec, and Quebec being itself about 400 miles up the river, Montreal is thus situated nearly 600 miles in the interior of Canada.

"The banks of the St Lawrence are here presented stretched out into smiling plains of most luxuriant appearance, in midst of which, and forming a main feature, is the garden-island of Montreal—producing grain and fruit, especially some description of the latter, in perhaps greater perfection than in any other part of the country. The size of this island is 32 miles in length and about ten in breadth, upon which is situated the city, covering above one thousand acres—with its quaint mixture of English, American, and old French architecture, in its streets, shops, English, American, and Scotch churches, French cathedrals and spires, and ancient convents. Rising from, and forming a sheltering background to the city on the north, is 'The Mountain,' as it is called, thickly wooded to the summit—an elevation of between 500 and 600 feet, commanding a magnificent view of the picturesque and luxuriant country around, the expanse of the St Lawrence, and the bold mountain scenery in the distance. Along the substantially-built stone wharfs skirting the south of the town, and towards the broadest channel of the river, lie throngs of ships, barges, and steam-vessels, loading and unloading the natural products of the interior, and the manufactures and other merchandise of Britain. Montreal, situated about 600 miles up the St Lawrence, forms the head of navigation for the large class of ocean vessels, and is the main point at which the produce of the interior arrives, in steam-boats, screw-propellers, and barges, for reshipment on board of the Atlantic vessels." [1]

Ocean vessels may now, however, by recent improvements of the internal navigation upwards through the great lakes, proceed with their cargoes many hundreds of miles further into the interior; thus opening up to Canada not only the

---

Canada.

fertile regions of her own most westerly districts, but the famous Far West of the United States, stretching even to the territories of the Mississippi; and it may be at no remote period to the yet distant shores of the Pacific.

Upper Canada.

We have now briefly to describe the leading features of Upper Canada. This division of the country, commencing about 80 miles up the St Lawrence from Montreal, upon the north side of the river, extends for about 100 miles further along this shore of the river to the city of Kingston, at the foot of Lake Ontario, and thence along the north shores of the great lakes Ontario, Erie, St Clair, Huron, and Superior, with their connecting rivers or straits, and stretching to the head waters of the streams which flow into Lake Superior. This great stretch of territory, with its almost unsurpassed extent of inland coast navigation, extends from 74. 30. to 117. W. Long.

The grand course of navigable waters directly inland through Canada, by the St Lawrence and great lakes, may be safely stated to exceed 2000 miles. The coast of the lakes alone has been estimated at upwards of 5000 miles.[1] The shores of this great valley, through which these waters take their course, embrace a country which has been styled "the garden of North America." It has already in our own day presented an increase in population, and in agricultural and commercial wealth, so wonderfully rapid as to be unprecedented in history.

Upper Canada, thus so favourably situated—comprehending one side of the entire upper portion of the great valley of the St Lawrence—is bounded on the south by the territories of the United States, on the north by the Hudson's Bay territory, and on the east by Lower Canada, while to the west extends that vast tract of country within British dominion, but as yet in a comparatively primeval state, and most generally known hitherto as the north-west Indian territory.

That portion of Upper Canada which has been set apart and divided for settlement, extends from its extreme eastern point, where it leaves Lower Canada, 80 miles above Montreal, and reaches along the northern shore of the St Lawrence, and upwards along the lakes to the shores of Lake Huron,—a direct course of about 700 miles. This breadth of settled country towards the north may be said to vary from 50 to 80 miles. Throughout the whole of this tract the soil is excellent, and is not surpassed by any other part of the American continent. It consists, generally speaking, of a fine dark loam, mixed with a vegetable mould, but it is in a great measure so varied as to present soils adapted to almost every species of produce.

From the commencement of Upper Canada to the head of the Bay of Quinte, on Lake Ontario, the land is spread out into an almost uniform level of great beauty, which rises only a few feet from the banks of the St Lawrence. It is in every direction well watered by numerous streams, which are generally navigable for boats and canoes, and at the same time present the most desirable situations for the erection of machinery.

Farther into the interior, along the course of the great stream of the Ottawa, which flows into the St Lawrence a short distance above Montreal, and between the Ottawa and Lake Ontario, the face of the country—which we have noticed as being spread out into a plain so attractive—is, in parts, here diversified by ridges and bold heights, and also by numerous streams and inland lakes. The Rideau canal, a work constructed by the imperial government for military purposes, passing through this part of the interior, from the town of Bytown, on the Ottawa, 120 miles above Montreal, through the country to Kingston—a distance of 135 miles—is almost one continued chain of natural lakes and streams. The chief link of these waters is Rideau lake, 24 miles in length, forming the summit level of the canal, and being 280 feet above the level of the Ottawa river, and 150 feet above Lake Ontario.

Lake Ontario.

Lake Ontario, which receives the waters of the upper lakes from the Niagara river, and discharges them into the St Lawrence, nearly 800 miles from the mouth of that river, may be said to be the first link in our upward progress of the chain of great lakes which so distinguish Canada, and confer upon the country unsurpassed means of internal communication. The height of this lake above the sea is 232 feet. It is 180 miles in length, 50 miles in breadth, and 470 miles in circumference. While the shores of this lake present the most populous and prosperous parts of Canada, the lake itself is believed to be the safest of the three lower lakes for the purposes of navigation. It possesses several excellent harbours; and from its great depth of 500 feet, compared with the two lakes above it, it is not so easily moved by storms as Lake Erie, while it is quite exempt from the shallows, or *flats*, as they are called, of Lake St Clair.

There are several pretty large islands scattered over the lower extremity of Lake Ontario, one of which, Amherst island, is about 10 miles in length and 6 in breadth. One of the most fertile and beautiful portions of this lake is the magnificent inlet of the Bay of Quinte, commencing near the city of Kingston, at the foot of the lake, and forming a spacious indentation of about 70 miles to the mouths of the rivers Trent and Moira. The shores of this bay are more diversified and pleasing in their features than those of the great lake itself, whose Indian name, "Ontario," signifies the Beautiful. Lake Ontario is never frozen over, and throughout winter steam-boats frequently run across the upper part of the lake from Toronto to Niagara when the weather is fine.[2]

All along the north shore of Lake Ontario, a distance of 180 miles, one extensive fertile plain presents itself, now and then agreeably sloping to the very edge of the lake, and bearing evidences of successful cultivation and progress. Several thriving towns are growing up rapidly along the shores of Ontario, the chief of which are Kingston at the foot of the lake, Toronto 35 miles from the head, and Hamilton at the extreme head. Toronto, which is very finely situated, spreading over a wide and gently rising plateau, and in a protected part of the lake shore, is the largest city of Upper Canada. The generally level stretch of well-cultivated plain which forms this northern shore of Lake Ontario is only partially broken by an inconsiderable ridge which runs through it, and which, coursing around the head of the lake, and crossing into the United States at the Falls of Niagara, forms the commencement of the extensive and fertile table-land which stretches westward from Lake Ontario, and, situated between Lakes Erie and Huron, forms the great western peninsula of Upper Canada.

Peninsula of Upper Canada.

The eastern boundary of this peninsula, thus situated between these three great lakes, is the neck of land of 36 miles between the shores of Lake Ontario, at Toronto, and Lake Simcoe, which communicates by means of the River Severn with the Georgian Bay on Lake Huron.

The settled parts of this great peninsula embrace about one-half of the settled parts of Upper Canada; and it is estimated to have at present a cultivated surface equal to about a fourth part of the cultivated surface of Scotland. This settled and partially occupied portion of the peninsula contains upwards of 9,000,000 acres. The entire district has been styled "the Garden of Upper Canada."

"I am delighted to have seen this part of the country," said the late Lord Sydenham, in recording his impressions to a

[1] *Prize Essay on the Canals of Canada*, by Thomas C. Keefer, C.E. Toronto, 1850.

[2] *Canadian Gazetteer*. By William H. Smith. Toronto, 1849, p. 95.

Canada.

friend, after having visited this district in the course of a tour which he performed in the capacity of governor-general of Canada, in the autumn of 1840—"I am delighted to have seen this part of the country; I mean the great district, nearly as large as Ireland, placed between the three lakes—Erie, Ontario, and Huron. You can conceive nothing finer! The most magnificent soil in the world—four feet of vegetable mould—a climate certainly the best in North America—the greater part of it admirably watered. In a word, there is land enough and capabilities enough for some millions of people, and in one of the finest provinces in the world."[1]

City of Hamilton.

Hamilton, situated at the extreme head of Lake Ontario, between 500 and 600 miles above Quebec, and nearly 1000 miles into the interior of Canada from the mouth of the St Lawrence, is the chief port of this valuable country westward. Its situation is commodious and picturesque, being at the head of a fine bay, locked in by a strip of land from the main lake, with the exception of a navigable passage for steam and sailing vessels. Immediately behind the town rise the agreeably wooded heights which form the commencement of the great and fertile table-land stretching westward.

The view from this elevation, called Burlington Heights, is one of the finest in Western Canada. The expanse of the waters of Ontario, surrounded by its wooded shores, speckled with towns and farm-settlements, spread themselves in panoramic view under the eye of the spectator; while stretching into the interior, northward, is the mass of primeval forest, almost in every direction broken by cultivated openings, with farms and rising villages. Clustering around the level shores of the bay beneath, and along the slopes, and in the wooded nooks of the picturesque eminence, are the many elegant residences and rows of wide streets of the young and prosperous city of Hamilton.

Following the chain of waters westward, the traveller approaches the Niagara river, 33 miles long, connecting Lakes Ontario and Erie. The town of Niagara is situated near the mouth of the river; and the small village of Queenston at the foot of the table-land which stretches westward, is about four miles further up. Queenston is about nine miles from the celebrated falls, and about 20 miles from Lake Erie. The scenery along both the United States and Canada sides of this beautiful river or strait, not to speak of its one stupendous feature, presents much both of grandeur and picturesque beauty.

Falls of Niagara.

Yet all is subsidiary to that one mass of falling waters, suggesting the idea of the great bed of the broad river having given way beneath their weight, and seeming to batter in vain upon the more solid rocks beneath to which they descend. The troubled and broken sheet of river assuming in its descent one mass of raging foam, and pouring down with incessant roar, whitening the entire stretch of precipice from bank to bank—presents a scene of unequalled grandeur and sublimity. Yet amid its features of stupendous magnificence, the interest of Niagara is heightened by noting others of calm and softest beauty. In all its turmoil may be noted the soft bow of the varied coloured iris resting in the sun beams, amid the light ascending spray, and that spray falling again, sprinkling the green fresh foliage which clings around the overhanging rocky cliffs. And not less striking to the observer of the great scene are the ever-playful eddies of the waters far beneath, laving the edges of the pebbled shore. There all is roar and turmoil—here, close by, soft and playful repose.

This great fall, which has been celebrated by all travellers as one of the greatest wonders of nature, is occasioned by the configuration of the country, which is one vast plain, extending from the Ohio and Lake Erie westward beyond the Mississippi, and eastward to the Allegany mountains. This plain, after passing Lake Erie to the north, rapidly descends 340 feet to another plain, in the level of which lies Lake Ontario; and it is from the higher level of Lake Erie that the river Niagara is precipitated with such tremendous violence into the plain below. The rock over which the Niagara falls is in the form of an irregular semicircle about three-quarters of a mile in extent. The river is here divided into two by Goat Island, the lower extremity of which is perpendicular, and in a line with the rock over which the water is precipitated. The cataract on the Canada side is called the Horse-Shoe, from its peculiar form, or the Great Fall; and the other, towards the south shore of the river, the American Fall.

Sir Charles Lyell, in his journal of a tour in North America in 1841–2, presents a very interesting and detailed account of these celebrated falls; and his very valuable geological observations are enhanced by excellent coloured illustrations.

Sir Charles Lyell on the Recession of the Falls.

"It has long been a favourite subject of discussion," observes Sir Charles Lyell, "whether the falls were once situated seven miles north, further down the river, at the village of Queenston. Here the descent from the platform, in a depression of which Lake Erie is situated, to the lower level of 330 feet of Lake Ontario, is sudden and abrupt.

"The strata throughout this whole region," continues Sir Charles, "are nearly horizontal, but they have a gentle dip to the south of 25 feet in a mile. This inclination is sufficient to cause the different groups of rock to crop out one from beneath the other, or to come up to the surface in parallel zones, which may be traced for a great distance east and west through the state of New York and Canada. They all consist of different members of the Silurian series, the uppermost or newest being those nearest to Lake Erie. The Niagara is bounded by low banks, where it issues from Lake Erie, and varies in width from one to three miles. It here resembles a prolongation of the tranquil lake, being interspersed with low wooded islands. This lake-like scenery continues for about 15 miles, during which the fall of the river scarce exceeds as many feet, but on reaching the rapids it descends over a bed of limestone about 80 feet in less than a mile, and is then thrown down about 165 perpendicularly at the falls. The largest of these, called the Horse-Shoe Fall, is 1800 feet, or more than a third of a mile broad, the island in the middle somewhat less in width, and the American Fall about 600 feet wide. The deep narrow chasm below the great cataract is from 200 to 400 yards wide, and 300 feet deep; and here in seven miles the river descends 100 feet, at the end of which it emerges from the gorge into the open and flat country, so nearly on a level with Lake Ontario, that there is only a fall of about four feet in the seven additional miles which intervene between Queenston and the lake. The great ravine is winding, and makes a turn nearly at right angles to itself at the whirlpool where the Niagara sweeps round a large circular basin. At some points the boundary cliffs are undermined on one side by the impetuous stream, but there is usually a talus at the base of the precipice supporting a very ornamental fringe of trees.

It has long been a popular belief, from a mere cursory inspection of the district, that the Niagara once flowed in a shallow valley across the whole platform from the present site of the falls to the Queenston heights, where it was supposed the cataract was first situated, and that the river has been slowly eating its way backwards through the rocks for a distance of seven miles. According to this hypothesis the falls must have had originally nearly twice their present height, and must have been always diminishing in grandeur from age to age, as they will continue to do in future, so long as the retrograde movement is prolonged. It becomes, therefore, a matter of no small interest and curiosity to inquire at what rate the work of excavation is now going on, and thus to obtain a measure for calculating how many thousands of years or centuries have been required to hollow out the chasm already excavated.

It is an ascertained fact, that the falls do not remain absolutely stationary at the same point of space, and that they have

[1] *Memoir of the Life of Lord Sydenham.* Lond., 1843.

Canada.

shifted their position slightly during the last half century. Every observer will also be convinced that the small portion of the great ravine which has been eroded within the memory of man is so precisely identical in character with the whole gorge for seven miles below, that the river supplies an adequate cause for executing the task assigned to it, provided we grant sufficient time for its completion.

The waters, after cutting through strata of limestone, about 50 feet thick in the rapids, descend perpendicularly at the falls over another mass of limestone about 90 feet thick, beneath which lie soft shales of equal thickness, continually undermined by the action of the spray driven violently by gusts of wind against the base of the precipice. In consequence of this disintegration, portions of the incumbent rock are left unsupported and tumble down from time to time, so that the cataract is made to proceed southwards. The sudden descent of huge rocky fragments of the undermined limestone at the Horse-Shoe Fall in 1828, and another at the American Fall in 1818, are said to have shaken the adjacent country like an earthquake. According to the statement of our guide in 1841, Samuel Hooker, an indentation of about 40 feet has been produced in the middle of the ledge of limestone at the lesser fall since the year 1815, so that it has begun to assume the shape of a crescent, while within the same period, the Horse-Shoe Fall has been altered so as less to deserve its name. Goat Island has lost several acres in area in the last four years, and I have no doubt that this waste neither is, nor has been, a mere temporary accident, since I found that the same recession was in progress in various other waterfalls, which I visited with Mr Hall, in the State of New York. Some of these intersect the same rocks as the Niagara—for example the Genesee at Rochester; others are cutting their way through newer formations, as Allan's Creek, below Le Roy, or the Genesee at its upper falls at Portage. Mr Bakewell calculated that in the forty years preceding 1830, the Niagara had been going back at the rate of about a yard annually, but I conceive that one foot per year would be a much more probable conjecture, in which case 35,000 years would have been required for the retreat of the falls from the escarpment of Queenston to their present site, if we could assume that the retrograde movement had been uniform throughout. This, however, could not have been the case, as at every step in the process of excavation the height of the precipices, the hardness of the materials at its base, and the quantity of fallen matter to be removed, must have varied. At some points it may have receded much faster than at present, at others much slower, and it would be scarcely possible to decide whether its average progress has been more or less rapid than now.

Unfortunately our historical evidence of the former condition of the cataract is meagre and scanty in the extreme. Sixty years ago the whole district between Lakes Erie and Ontario was a wilderness in which the Indian hunter chased the bear and the buffalo.[1]

Future Retrocession of the Falls.

In regard to the future retrocession of the falls, Sir Charles Lyell observes, that when they have travelled back two miles, the massive limestone now at the top of the falls will then be at their base; and its great hardness may then perhaps effectually stop the excavating process, if it should not have been previously arrested by the descent of large masses of the same rock from the cliff above. It will also appear that the falls will continually diminish in height, and should they ever reach Lake Erie, they will intersect entirely different strata from those over which they are now thrown.

Impressions of the Falls.

The first impressions of Sir Charles Lyell, like those of many others, were not what he expected, but closer intercourse, as most usually is the case, in time rewarded him by the great scene revealing itself in its true grandeur. "We first came in sight of the Falls of Niagara when they were about three miles distant. The sun was shining full upon them—no building in view—nothing but the green wood, the falling waters, and the white foam. At that moment they appeared to me more beautiful than I had expected, and less grand; but after several days, when I had enjoyed a nearer view of the two cataracts, had listened to their thundering sound, and gazed on them for hours from above and below, and had watched the river foaming over the rapids, then plunging headlong into the dark pool, and when I had explored the delightful island which divides the falls, where the solitude of the ancient forest is still unbroken, I at last learned by degrees to comprehend the wonders of the scene, and to feel its full magnificence."[2]

The falls are most frequently viewed from a jutting shelf of the rock, called Table Rock, on the British side, which is on a level with the edge of the cataract; but the grandeur of the spectacle is still more striking on the same side, below the falls, at the bottom, the descent to which is partly down the less steep part of the bank, and partly by a spiral ladder, from the bottom of which a kind of path leads, among rocks and under the precipitous banks, to the crescent or great Horse-Shoe Fall. "Here," says Mr Macgregor, in his work on British America, "we have the grand outlet of these great lakes, which contain nearly half of all the fresh waters on our globe, thundering over a terrific precipice, having for a short distance a smooth green surface, but quickly raging in impetuous, broken, foaming, grandeur, as it hurls into the vast unfathomable abyss below." The precipice over which the cataract rolls projects about fifty feet beyond its base, and hence the waters descend in the form of a crescent, within which it is customary for travellers to enter thirty or forty yards. Mr Weld, who visited Niagara in 1796, was among the first travellers who ventured under the cataract, and to within six yards of the sheet of water which rushes into the gulf below. Captain Hall also took his station under the cataract; and both travellers experienced the greatest inconvenience, and even some risk, from the violent tempest and whirlwind which always rages at the bottom of the cataract, arising from the air carried down by the cascade, and forced under the water, rising up again in tremendous gusts, and driving upward incessant deluges of the spray.[3]

The appearance of Niagara, and the surrounding country, has been very greatly changed by the progress of cultivation. There are several excellent hotels near the falls, the windows of which command a view of the cataract. At the village of Manchester, on the United States side, mills, forges, trip-hammers, &c., are erected close to the rapids, which turn the wheels of the mills and forges; and thus some portion of the scenery has exchanged its original character of wildness and grandeur for the softer aspect of civilized life.

Lake Erie.

Having now parted from Niagara, we pass to the shores of Lake Erie. The obstruction to navigation caused by the Falls of Niagara is obviated by the Welland canal, which cuts through the neck of land situated along the course of the Niagara river, and thus unites Lakes Ontario and Erie for the purposes of navigation. Lake Erie, which is situated 565 feet above the sea, and 333 feet above the level of Lake Ontario, is about 265 miles in length, from 30 to 60 miles in breadth, and between 600 and 700 miles in circumference. Its mean depth is 120 feet, being the shallowest of all the great lakes, and most easily frozen. Its waters are also, on account of its shallowness, more readily agitated by storms, causing its navigation to be therefore more dan-

[2] *Travels in North America*, vol. i. chap. ii. p. 27.

[3] For a more particular description of this fall, the reader is referred to Chateaubriand's *Recollections of America*, p. 184; Volney's *View of the Climate and Soil of America*, &c., chap. vi.; Weld's *Travels*, vol. ii. p. 123–9; Heriot's *Travels*; Howison's *Sketches of Upper Canada*, Letter vii. p. 91; Captain Hall's *Travels in North America*, vol. i. chap. vi.; Sir Charles Lyell's *Travels*, vol. i. chap. xi.; *Views of Canada and the Colonists*, 2d Edit. chap. iii.

Canada. gerous during stormy weather. Disasters, involving large loss of life and property, are not of unfrequent occurrence on this lake, toward the close of navigation, before the rigours of winter have put a final stop to all active lake traffic.

The shores of this lake present features very similar to those of Lake Ontario; the banks of Lake Erie being generally bolder and more elevated, and composed chiefly of clay and sand. The more fertile parts are at some distance from the banks, throughout the extensive plain of table-land beyond. There are several good natural harbours along the shore, formed chiefly by the mouths of deep creeks or streams, and protected from the action of storms and current of the lake by strong projecting piers. Among the harbours of Lake Erie may be mentioned Port Colborne, situated at the entrance to the Welland canal, at the foot of Lake Erie, and a little above the commencement of the Niagara river. A little further up is the harbour of Port Maitland, at the mouth of the Grand river. This is a very fine and capacious stream, navigable for small vessels a considerable distance, and possessing much fertile land and pleasing scenery along its banks. The shore of the lake for some way above the mouth of the Grand river presents many delightful and fertile settlements. Among the harbours further up the lake are Ports Dover, Burwell, and Stanley. Port Stanley is perhaps the most flourishing of these harbours, being the port of one of the most populous and enterprising districts of this part of Canada, and situated near the centre of the great fertile peninsula.

The banks of Lake Erie are here high, and of a sandy character; but off the immediate bank, and extending all the way through the extensive tract of country, to the town of Goderich, on Lake Huron, a distance of 85 miles, the soil is of the best quality, being for the most part timbered with beech, maple, black and white walnut, oak, ash, cherry, and other trees, indicating the first qualities of soil. The whole tract is greatly undulating in its appearance, and is everywhere well watered.

The upper part of Lake Erie is distinguished by many beautiful islands, the largest of which is Pele, on which there is a lighthouse, and several farms. The shores along the upper part of the lake, especially towards the mouth of the Detroit river, have a smiling and luxuriant aspect. Trees of the finest growth rise from the shore, and the wild vine may be seen twining and clustering among the branches of the lesser trees and tall shrubs along the sloping banks. The shore is here covered with fine white sand.

In our further progress up this country, we pass the Detroit river, thence into Lake St Clair, then the River St Clair, which last opens into the broad expanse of Lake Huron. From the head of Lake Erie to the foot of Lake Huron, is a distance of between 80 and 90 miles, through a country of unsurpassed fertility and luxuriance, and possessing many delightful features. The Detroit river, about 27 miles in length, is interspersed with many islands, several of which, near its entrance into Lake Erie, are beautifully wooded. The towns of Amherstburgh and Sandwich, and the small village of Windsor, are situated along the Canada side of this river. Opposite Windsor, towards the upper part of the river, and where the banks narrow to about three-quarters of a mile, is the American city of Detroit, in the state of Michigan.

Lake St Clair. Lake St Clair, which forms the connecting link, by means of the St Clair and Detroit rivers, between Lakes Huron, Michigan, and Erie, is the smallest of all the lakes, and exceedingly shallow for the larger class of vessels passing through it. It is from 20 to 30 miles in length, and about the same in breadth. Its average depth is about 20 feet, but the principal channel used by vessels passing through it is much shallower, especially in dry seasons, when the mud of its *flats* is stirred to the surface not unfrequently by large vessels. The chief stream which it receives from the Canadian shore is the River Thames, which is navigable for lake vessels 22 miles from its mouth, and the banks of which are exceedingly fertile, and mostly well settled. Much of the land bordering on the lake is low and marshy. In the upper part of the lake are several islands, the principal of which is Walpole island, about 10 miles long, and from 3 to 4 miles wide. This island is inhabited by a stray portion of the remnant of Indians still existing in small and decreasing numbers in Canada.

We are now at the entrance to the River St Clair, in length about 30 miles. There are several thriving settlements along the fertile and beautiful banks of this river. Towards the lower part, amid a cluster of wooded islands, the banks, with somewhat of a flat appearance, are covered with luxuriant timber. Farther up the land rises, with finely sloping banks and cultivated farms. Near the head of the river, and pleasantly situated, is the flourishing town of Sarnia.

The River St Clair now opens to the wide expanse of Lake Huron, of about 1000 miles in circumference. Lake Huron.

This vast sheet of inland sea is the second in point of size of the great lakes, yielding only in this respect to Lake Superior. The surface of Lake Huron is about 30 feet above the level of Lake Erie, and 595 feet above the level of the Atlantic. The length may be estimated at 250 miles, and its breadth 160 miles, inclusive of the Georgian bay, a large wing of the lake, extending along the north-eastern shore for a distance of about 100 miles. The mean depth of Lake Huron is 900 feet, and its greatest depth 1000 feet near the west shore.

This lake is said to contain the almost incredible number of 32,000 islands, principally along the northern shore and at the north-western end, varying in size from mere rocky reefs and pinnacles to large and cultivable islands. The Great Manitoulin, the longest of the islands, is upwards of 75 miles in length, and varies in width from 3 to 23 miles. The waters of the lake are remarkably pure, clear, and cold; in these respects resembling the great upper Lake Superior. The surface of Lake Huron is about 32 feet lower than that of Lake Superior, and it is very nearly as deep as that lake. The nature of the banks of Lake Huron vary very much. In parts they are low and sandy, in others formed of clay; they rise to a height of about 120 feet, while again the shore of this inland sea presents a bold, rocky, iron-bound coast, having great depth of water to the base. Numerous streams descend on all sides into the lake; and among its rivers may be mentioned the Maitland, Severn, and River Francais. The lake, which is rather subject to storms, is deficient in good natural harbours, the principal of which, along the eastern coast, are Goderich, at the mouth of the Maitland, Saugeen, and Penetanguishene; and on the western shore the best places of shelter in heavy weather are Thunder bay and Saginaw bay.

Lake Huron possesses the advantage of being remarkably centrically situated with respect to the other great lakes. With Lake Erie, as we have seen, it is connected by the straits or rivers St Clair and Detroit, and the small lake St Clair. Lake Ontario, the lower of the lakes, is even open to it by the river Severn, Lake Simcoe, then by a short portage, a chain of lakes, and Trent river. Lake Simcoe, thus situated between Lake Huron and Ontario, is a very beautiful lake about 30 miles in length and 20 in breadth. The neck of land south of Lake Simcoe from Holland river leading to Toronto is, it will be remembered, about 36 miles; and again, north of Lake Simcoe, from the narrows of this lake to Lake Huron, the postage is only about 14 miles. The new railway now cutting through this neck of the peninsula westward, situated between the lakes Erie, Ontario, and Huron, will greatly facilitate the growing intercourse between the shores of Ontario, as well as all the country lower down along the banks of the St Lawrence, and also great part of the United States,

Canada.

with the regions of the great upper lakes, Huron and Superior. This direct course will no doubt be much preferred to the circuitous route through Lakes Erie and St Clair, and the connecting rivers.

Lake Huron, besides, communicates with the Ottawa, and thence with the St Lawrence above Montreal, by means of French river, Lake Nipissing and the river Mattawa into the Ottawa. This is the route adopted generally by the north-west traders in proceeding to the remote parts of the country, and it is also the one by which Europeans first penetrated the West. The distance from Montreal by this route to Lake Huron is fully more than one-half shorter than that by the St Lawrence. From Montreal to the Georgian bay, the distance is estimated at 400 miles, while by the St Lawrence the distance is upwards of 1000 miles.[1] Again, Lake Huron communicates with the great upper Lake Superior by means of the river St Mary about 40 miles in length. Lastly, we have this centrically situated lake communicating by the straits of Mackinac with Lake Michigan, and thence by the Illinois river and canal with the Mississippi and Gulf of Mexico.

The shores of Lake Huron have of late revealed important mineral treasures. The Bruce copper mines promise to be of great value. These mines are situated upon the northern shore of the lake under the Cloche mountains, a bold range of hills extending about 40 miles along the coast.

Along the south-eastern shores of the lake, extending beyond the town and harbour of Goderich, on the River Maitland, are many highly prosperous settlements. The lands in this direction, and through the large and fine district inland, are believed to be the most fertile in Canada. The country is everywhere well watered, and enjoys much delightful scenery, both along the elevated banks of the lake, and the beautiful rivers which diversify it. The town of Goderich, on the River Maitland, is very agreeably situated, and possesses an excellent harbour. The high banks of the Maitland are exceedingly picturesque.

Lake Superior.

We now approach the uppermost of these vast collections of waters, not inappropriately named inland seas. The river or strait of St Mary, connecting Lake Huron with Lake Superior, is between 30 and 40 miles in length. The character of the scenery, on entering St Mary's Channel, is the most delightful that can be imagined. The channel throughout, with the exception of several small lakes, seems to be almost packed with islands; and while perplexing the navigator by its intricacy, it is every now and then revealing new and striking beauties of wooded heights and steep banks clothed with verdure, and spots of flat, fertile meadows, and, at times, bare, rocky, fantastic crags. The sides of the ridges of table-lands that skirt the country, around the borders of Lake Superior, appear in the distance clothed with one mass of lively green.

The foot of the Falls, or more properly speaking Rapids of St Mary, approach within about 18 miles of Lake Superior. The region in this direction seems much less fertile; the trees along the shores of the broad strait appearing to be chiefly of the pine species, and the soil in many parts light and sandy, while the lands close upon the banks lie for the most part low and flat. We now approach the chief seat of the great copper district of America, where the barrenness of a large portion of the country is richly compensated by the value of the metals with which it abounds. The copper mines of Canada, along the shores of Lakes Huron and Superior, are perhaps entitled to rank among the most valuable resources of this great country.

As we approach the great queen lake or inland sea, upwards of 400 miles in length and 130 in breadth, dark blue masses of hills uprise, somewhat reminding the voyager of the approaches to the St Lawrence in the forms of the headlands of Cape Rozière and others, yet being neither so high nor so bold as these. The main entrance to the lake is marked by two such rocky headlands, one upon either shore several miles apart. From the heights of the one on the other shore, named Gros Cap, composed of the rock of the old red sandstone, the sides of which are partially covered with junipers, blue bells, wild briars, and other vegetation, reminding one of the Scottish hills, we overlook a scene of the most imposing and still grandeur possible to be imagined. The dim distance into the lake is bounded by vast islands, and along both shores bold uneven banks uprise, apparently covered with dark dense foliage, and stretch themselves in irregular course, as far as the eye can reach, along the wide expanse of water that scarcely as yet presents any speck of navigation. The shores of Lake Superior, which are even now imperfectly explored, already prove to be abundant in mineral resources. Many of the enterprising inhabitants of Canada, having formed themselves into associations, are now engaged in mining the seemingly inexhaustible treasures of virgin copper which are found along the shores of this lake as well as Lake Huron. This source of wealth to the colony is likely to prove of considerable importance.

Lake Superior, which is the largest sheet of fresh water on the face of the globe, is the most remarkable of the great American lakes, not only from its magnitude, but also from the picturesque scenery of its borders, and the interest and value attaching to its geological features. "As a mining region," continues Dr Jackson, who, as United States geologist, was intrusted by his government to survey the territory, "it is one of the most important to this country, and is rich in veins of metallic copper and silver, as well as in the ores of those metals. At the present moment it may be regarded as the most valuable mining district in North America, with the exception only of the gold deposits of California.[2]

Coast of Lake Superior.

The whole coast of Lake Superior, we are informed by Dr Jackson, is rock-bound. Mountain masses of considerable elevation in some places rear themselves from the immediate shore, while steep precipices and frightful crags oppose themselves to the surges of the mighty lake, and threaten the unfortunate mariner who may be caught in a storm upon a lee shore with almost inevitable destruction. The northern or Canadian shore of the lake is the most precipitous, and consequently most dangerous to the navigator. Good harbours for vessels of moderate capacity are comparatively few, but there are abundance of coves or boat-harbours formed by the countless indentations of the rocky coast. In remarkable contrast to Lake Huron, which is thickly studded with islands, there are very few islands in Lake Superior.

Agriculture may be truly said to have not yet commenced to tame the great and comparatively unexplored wilderness around the shores of Lake Superior. The forests of stunted spruce and fir-trees along the immediate coast of the lake are said to afford a very inadequate idea of the agricultural resources of the shores of the great queen lake. The cold air from the lake, says Dr Jackson, affects only the vegetation near its shores, while further inland the temperature more resembles that of the settled parts of Canada. The native forest trees, and also the flowering plants, as well as the agricultural produce where clearings have been made, are believed to afford very satisfactory evidence on this

[1] Despatch from the Earl of Elgin, Governor-General, &c. Quebec, August 16, 1853.

[2] *Geology, Mineralogy, and Topography of the lands around Lake Superior*, by Charles T. Jackson, M.D., late United States Geologist, &c. Appended to I. D. Andrews' *Report on Colonial and Lake Trade to the Senate of the United States.*

Canada. point. The forests are filled with excellent timber for building purposes; the white and yellow pines, particularly, being of large dimensions. "The tributary rivers of Lake Superior are numerous," says Mr I. D. Andrews, in his very interesting report to the United States senate, "and, bringing down a large volume of water, afford superabundant water-power for manufactories, the most extensive in the world, though from their precipitous descents and numerous falls and chutes, they can never be rendered navigable for more than a few miles above their mouths except for canoes."[1]

The importance to Canada of the varied resources of the shores of the great lake, as well as its very valuable fisheries, cannot yet be fully appreciated. The mines, with their inexhaustible riches of silver and copper, were only discovered so lately as 1844; and although geological surveys have been made both by the United States and Canadian governments, yet much remains to be ascertained respecting this region. A ship and steamboat canal, on the United States side, now unites the upper and lower sections of the St Mary's River, by which vessels in transit between Lakes Huron and Superior may avoid the rapids between the latter and the lower waters. The uninterrupted navigation between the great queen lake and the rest of the vast chain of inland waters thus acquired, will not only materially facilitate the traffic of the mining associations, but will also rapidly develop this part of Canada, so rich in promise to the commercial interests of the country. The commerce of the vast region bordering on Lake Superior will thus be opened up, and to the already unrivalled inland navigation of about 1500 miles from tide-water at Quebec, will be added a further direct length of at least 500 miles, and a coast navigation around the shores of Superior of not less than 2000 miles.[2]

Climate and Seasons of Canada.

The severity of winter in Canada is very commonly much exaggerated in England. The thermometer in the dry, clear, bracing atmosphere of this colony is, to a certain extent, a rather imperfect guide to the inquirer accustomed to its ranges in the raw damp atmosphere of our own islands. Throughout the greater part of the winter season in Canada, the cold in the open air is by no means unpleasant.

During a comparatively few days only the degree of cold is uncomfortable. Persons who have resided in Canada not unfrequently observe that they have experienced more disagreeable sensations from the raw easterly winds of spring or autumn, while travelling in this country, than they have in the depth of winter in Canada, though travelling in an open sleigh. This fact of open sleighs being used throughout the whole winter, is one of the best proofs of the enjoyable nature of the climate. With good horses, and a well-beaten snow-path on the principal roads of the country, the exercise of sleigh-driving is most exhilarating. The horses with their tinkling bells on their necks, seem to participate as they bound along, in the enjoyment of the pure bracing atmosphere. Warm clothing and good heavy furs are all that are requisite to ensure complete comfort in an open sleigh, in the depth of winter in Canada.

The four coldest months of the year are November, December, January, and February. By observations made at Toronto and at Greenwich from 1840 to 1847 inclusive, the average quantity of snow at Toronto in November was very little over 2 inches. The average quantity of rain was a little over $3\frac{1}{4}$ inches. The average quantity of rain at Greenwich was not quite $3\frac{1}{4}$ inches. The mean temperature at Toronto in November was 35·50°; at Montreal, 32·36°; and at Greenwich, 44·57°. The mean highest temperature at Toronto was 56·26°; at Montreal, 59·25°; and at Greenwich, 59·59°. The mean lowest at Toronto was 12·21°; at Montreal, 7·75°; and at Greenwich, 26·50°. The colder nights and mornings in Canada, compared with England, have now set in, while the mean highest temperatures in both countries, so far as Upper Canada is concerned, differ only by about three degrees of the thermometer; and with regard to Lower Canada, the mean temperature at Montreal in November was almost precisely the same as in England in that month to a fraction of a degree. Another series of observations extending to eight years in Canada and four in England gave the mean highest temperature in November, in Upper Canada and England, at precisely the same. And with regard to Lower Canada, the mean highest temperature at Montreal in November was the same as in England during that month to a fraction of a degree.

Winter. In December, when winter has fairly commenced, the average quantity of snow at Toronto was 6 inches. The average quantity of rain was not quite $1\frac{3}{4}$ inches, and at Greenwich it was not quite 1 inch. The mean temperature at Toronto was 27·62°; at Montreal, 18·50°; and at Greenwich, 39·97°. The mean highest at Toronto was 45·71°; at Montreal, 42°, and at Greenwich, 54·43°. The mean lowest at Toronto was 0·18°; at Montreal, 10·75°, and at Greenwich, 24·94°.

The coldest month of the year in both countries, so far as the result of these observations go, which we have taken for our guidance—is the month of January. The mean temperature of this month at Toronto was 24·64°, and at Greenwich it was 37·79°. The mean highest temperature at Toronto was 45·79°, and at Greenwich, 52·83°. The mean lowest at Toronto was 5·12° and at Greenwich it was 20·97°. We have now for the first time the thermometer below zero at Toronto, to the the extent of a little over five degrees. At Montreal the mean lowest temperature for January was 15·50°, the mean temperature 18·58°, and the mean highest 42°. The average quantity of snow at Toronto in January was slightly over 13 inches. The average quantity of rain was not quite $2\frac{1}{2}$ inches; at Greenwich it was a little over $1\frac{1}{2}$ inch.

We now arrive at February, when the cold, according to our present data, has commenced to be less severe. Observations from another series of years might show the cold in February to be quite as great as in January, and perhaps more so, as it sometimes is in particular seasons. The winters in Canada, as in England, vary a good deal. Certain seasons are much more open and less severe than others. The months also differ at times in their general character. By the observations which we have now for our guidance, however, the difference in the mean lowest temperature between the two months of January and February is very slight. At Toronto, in February, the mean lowest temperature was 4·59°. At Montreal it was 13·50°. At Greenwich the mean lowest temperature was 17·70°. The mean temperature at Montreal was 13·32°, at Toronto, 24·21°, and at Greenwich, 37·06°. The mean highest temperature at Montreal was 40·25°, at Toronto 45·32°, and at Greenwich 53·70°. The average quantity of snow at Toronto in February was slightly over 21 inches. This month gives the greatest quantity of snow. The average quantity of rain in February was not quite 1 inch. At Greenwich it was slightly over $1\frac{1}{4}$ inch.

March now brings milder weather. The mean lowest temperature in this month at Montreal was 4·20°, and at Toronto it was 4·74°. At Greenwich it was 23·79°. The mean temperature at Montreal was 28·96°, and at Toronto 30·49°. At Greenwich the mean temperature was 42·20°. The mean highest temperature at Montreal was 57·40°, at Toronto 54·14°, and at Greenwich 61·84°. The average

[1] I. D. Andrews' *Report*, p. 231.

[2] *Report of the Commissioner of Public Works.* Quebec, August 1852.

Canada.

quantity of snow at Toronto was very little over 9 inches. The average quantity of rain was a little over $1\frac{1}{4}$ inch. At Greenwich the average quantity of rain in March was not quite 1 inch.[1]

Depth of Snow.

The depth of snow usually is from eighteen inches to two feet; the depth of frost in the ground from twelve to eighteen inches. The appearance of the snow is hailed with much pleasure, both as the means of enjoyment, and as affording facilities to the farmers for bringing their produce to market. The absence of good sleighing at any time during the winter season is universally considered a loss in limiting the means both of business and pleasure. The first snow, of any amount, very usually falls in Lower Canada about the beginning of December, and in Upper Canada about two or three weeks later. The months of January and February are the best for good steady sleighing. The season for this pastime lasts fully a month longer in Lower Canada than in the upper or western parts of the province. The more south-westerly parts of Upper Canada, such as along the shores of Lake Erie and the Detroit river, have the shortest winter of all, and least sleighing. The continuance of this amusement at any period of the season in Upper Canada is not much to be depended upon, on account of the rapid thaws which take place occasionally, causing the snow almost wholly to disappear in a day or two, under the influence of the warm south wind and the rays of the sun. The heaviest of these thaws in Upper Canada takes place, with periodical regularity, in the month of January, and is known as the January thaw. Sleighing continues with much greater steadiness in Lower Canada, where complete thaws less frequently occur. Snow finally disappears in Lower Canada about the middle of April; and in Upper Canada, especially the more western parts, about a month earlier. Then, under the influence of the genial south wind, all traces of winter rapidly disappear.

Spring.

Ploughing usually commences in Upper Canada about the middle of April. In the south-westerly parts of the country the period is a little earlier, and in the more easterly and northern districts, about a week or two later. Cattle are put out to graze from about the middle of April to the beginning of May. They are frequently at first turned into the woods, where they crop the tender growth, as the fields afford very little good pasture until after the 1st of May. The usual time for taking them into shelter, before winter commences, is about the middle of November. Harvest begins about the 1st of August.

Summer.

The luxuriance of early summer in Canada is gorgeous. With the pure atmosphere, and fertile soil, the forests rapidly assume all the freshness and beauty of their summer green.

During the month of June and the latter part of May nature is seen under the most delightful aspect. The days are seldom disagreeably warm. The really hot days are in the month of July. The weather then towards noon, and not unfrequently during the night, is oppressively hot, and very enervating; but this oppressive weather only continues a few days. The summers are somewhat hotter in Lower Canada than in Upper, just as the winters are longer and more severe in the lower or more northerly part of the province. The heats of summer, however, in Canada, have probably been as much exaggerated in England as the frosts and snows of winter.

The mean highest temperature at Montreal in May was 65·40°, at Toronto 77·16°, and at Greenwich 77·59°. We here observe how very closely the mean highest temperatures of England and Upper Canada in the month of May approach each other—a mere fraction of a degree of the thermometer of difference. The mean lowest at Montreal was 33·20°, at Toronto 39·08°, and at Greenwich 36·79°. The mean temperature at Montreal in May was 56·12°, at Toronto 52·59°, and at Greenwich 53·64°. The average quantity of rain at Toronto in May was not quite 2 inches. At Greenwich the quantity was a little over $1\frac{1}{2}$ inch.

In June the highest temperature at Montreal was 92·50°, at Toronto 83·80°, and at Greenwich 84·04°. We have here the highest temperature for the month of June in Upper Canada very much the same as in England. The mean temperature approaches still more closely in the two countries. In Upper Canada, at Toronto, it was 60·87°, and in England, at Greenwich, it was 60·03°. Lower Canada has warmer weather. The highest temperature in Lower Canada, at Montreal, in June, was 66·79°. The average quantity of rain in June at Toronto was nery nearly $3\frac{1}{2}$ inches. At Greenwich the quantity was a little over $2\frac{1}{4}$ inches.

The mean temperature of the month of July at Montreal was 71·36°; and at Toronto the mean temperature of the month of July was 66·12°. The mean temperature of July at Greenwich was 61·43°. The mean highest temperature at Montreal in July, was 97·90°; at Toronto, 88·28°; and at Greenwich, 85·37°. The mean lowest temperature at Montreal for July, was 53·25°; at Toronto, 42·86°; and at Greenwich, 45·80°. The average quantity of rain for July at Toronto, was 3·803 inches. At Greenwich for July the average was 2·049. The quantity of rain which falls at Greenwich, it may be observed, is understood to be less than the average for all England.[2]

Prevailing Winds.

The prevailing winds of Canada are the S.W., the N.E., and N.W. The S.W., which sweeps down the valley of the St Lawrence, over the rivers and great lakes, for about two-thirds of the summer season, carries with it a portion of the warmth of the region of the Gulf of Mexico and valley of the Mississippi. The N.E. wind is damp and chilly. The N.W. wind, which is most frequent in winter, is dry, cold, and elastic. The most sudden changes of wind are to the N.W., followed by weather clear and cold for the season. Heavy thunder showers clear off most frequently with this wind. These showers frequently precede the hard frosts which introduce winter. The longest storms of rain, and deepest falls of snow are usually accompanied by easterly winds. The wind blows less frequently from the west and south, and still seldomer from due north.

The great lakes of Canada are not frozen over during winter. Lake Erie alone, which is very shallow, is said to have been frozen over only two or three times within the last forty years. Only the bays and shores of the lakes, for a considerable distance from land, are frozen; and the ice in such situations, and on the rivers, is so thick and strong, that heavy loaded sleighs pass over it with perfect safety. The steamboats on Lake Ontario, between Toronto and Niagara, not unfrequently continue running through the whole winter. The steamboats plying across and along the lower part of the lake, generally continue running till about Christmas. The navigation of the St Lawrence almost invariably opens from about the middle of April to the beginning of May; when the first steamboats arrive at Quebec from Montreal, a river voyage of 180 miles.

The short but very delightful period of Indian summer, which occurs usually about the end of October or beginning of November, is a chief peculiarity of the Canadian climate. The period of its duration is variable, being from a few days to two or three weeks. The atmosphere is most

[1] *Views of Canada and the Colonists*, 2d Ed. chap. xxii. p. 328–333.

[2] The data respecting the temperature of Lower Canada are the results of observations at Montreal, derived from the registers published monthly in the *British-American Journal of Medical and Physical Science*, from 1845 to 1848 inclusive. The data for Upper Canada are deduced from the records of observations of the Royal Observatory at Toronto for nine years, from 1840 to 1848 inclusive. The data for Greenwich are from the records of the Royal Observatory there for seven years, from 1841 to 1847 inclusive.

Canada.

agreeably soft, accompanied with a peculiar and not unpleasant haziness, mellowing the rays of the sun; which has led to a popular belief that the Indians, far to the south, are then setting fire to their great prairies, and that Canada is getting a share of the distant smoke.[1]

Soil and Productions.

The soil of Canada is generally loam in its varieties, with a substratum of gravel; and when in a state of nature the surface is usually covered with a vegetable mould of some depth, formed from the decayed timber and leaves of the forest.

The Reports of the Geological Survey of Canada, under Mr W. E. Logan, provincial geologist, present very strikingly the vast resources of the lands of Canada. Entire districts of many square miles in extent are found to be composed of alluvial deposits from 30 to 40 feet deep of soil, in places so rich as to bear good crops of wheat for successive years without manure. Others of nearly equal value are found resting on red sandstone, trap, serpentine, limestone, and other strata, most favourable for agriculture. There are also, as along some of the rivers, for miles in succession, soils too rich for wheat, others of a good sandy loam, suitable to and requiring the usual English rotations. In many parts of Canada, on the other hand, there exist considerable quantities of poor, thin, and stony soils. The Reports of the Geological Survey, in presenting an account of the geological distribution of the various strata, and their agricultural capabilities, will prove of great value to the emigrant landholder, and others less or more interested in the lands of Canada.[2]

The soil and climate of Canada are such that the country produces a much greater variety of grains and fruits than is usually grown in Great Britain or Ireland. Besides wheat, barley, oats, rye, pease, turnips, potatoes, hemp, flax, hops, and the other ordinary agricultural products of England, which are all raised in abundance, Canada grows tobacco, rice, maize or Indian corn, and fruits of warmer climes than the British Islands. The full and steady heat of the summer matures with surprising rapidity the most valuable productions. "The severity of the winter," observes a very well-informed writer on the resources of the country, "are indeed unfavourable to grazing, and increase the consumption of fuel; yet without the ice and the snow the now invaluable timber of our extensive forests would be comparatively worthless. And inasmuch as we do not find the fertility of the soil impaired by the frost, we are justified in assuming that our winters have the same invigorating effect upon the earth, for our peculiar productions, as that conferred by rest upon the human frame: and that when the mantle of snow is removed, the soil, 'like a giant refreshed by sleep,' is enabled to send forth that rapid and luxuriant vegetation which renders a longer summer unnecessary."[3]

Fruits.—The fruits of Canada embrace every description usually grown in England, besides others which are produced in that country only with great care and by artificial means. The finest melons are grown in abundance in the open ground in Canada; and in some seasons peaches are so plentiful in the south-western parts of the country, along the shores of Lake Erie and the Detroit river, that they have been sold for one shilling sterling per bushel. The vine is also cultivated in open gardens around parts of those favoured shores, and grapes of perfect size and excellent flavour are produced. Apples, pears, plums, cherries, raspberries, currants, and strawberries are all grown in every part of Canada in great perfection and abundance.

Canada.

The shores of the Niagara and Detroit rivers are particularly famed for the excellence and abundance of their fruits. The island of Montreal, too, in Lower Canada, produces apples so highly esteemed for their choice and rich flavour as to be perhaps unsurpassed in any country.

Wild fruits abound in great variety in the woods and elsewhere all over Canada. The wild vine (*Vitis vulpina*) is very frequently seen luxuriantly clustering and twining its tendrils around the trunks and over the branches of the forest trees, forming all sorts of fanciful bowers. Among the other wild fruits may be mentioned cherries, raspberries, strawberries, whortleberries and blueberries, black and red currants, gooseberries, juniper berries, plums and hazle-nuts. Cranberries of large size grow in marshes in certain parts of the country very plentifully; and are much used as a favourite preserve.

Almost all kinds of vegetables necessary or desirable for the table, and in greater variety than in England, grow luxuriantly in Canada, and are cultivated with very little trouble. Cabbages, cauliflower, broccoli, pease, French beans, spinach, onions, turnips, carrots, parsnips, radishes, lettuces, beet, asparagus, celery, rhubarb, tomatoes, cucumbers, are all grown very successfully in Canada, and in great abundance. Indeed, the fruits and vegetables of Canada, in their abundance and excellence, are not only among its choicest luxuries, which nature in most liberal profusion places alike within the reach of poor and rich; but they are besides, no doubt, a very principal means of promoting the health, as well as adding to the comfort of the inhabitants during the hot summer months of the country.

Flowers.—Flowers grow in great variety, and in rich profusion, favoured by the soft genial atmosphere of a Canadian summer, and one of the most kindly soils. The woods in many places are literally carpeted with them. "Many of the cherished pets of our gardens and greenhouses are here flung carelessly from Nature's lavish hand among our woods and wilds," writes the accomplished authoress of the *Backwoods of Canada*.[4] Amongst the variety of Canadian wild flowers, may be mentioned a few, such as the scarlet lobelia, blue lupin, purple gentian, columbine, violets in great variety, honeysuckles, campanula, hare bell, Michaelmas daisy, pitcher plant, two-flowered balsam, rasp-leaved aster, calceolaria, lily of the valley, besides wild roses in profusion, with their sweet perfumes; and among the grass of the meadow land, and by the stream side, are to be found the well-known spearmint and peppermint. Besides these, there is the magnificent white water-lily, the queen of aquatic plants. The shallows of the lakes, and quiet nooks of rivers, present at times so gorgeous and beautiful a sight, as to be not inaptly compared to floating gardens.

Forests.—The forests of Canada abound in the finest and largest trees, adapted to almost every variety of purposes, useful or ornamental. Amongst the monarchs of these forests are the white and red pine, of which so large quantities are annually imported into Britain from the St Lawrence. Individual trees of the white pine are frequently found measuring 100 feet to the first branch, and occasionally trees reach 200 feet in height.

The pine timber cut for the Quebec market is usually in logs of about 20 inches square by 60 feet in length. Besides these, the growth of the Canadian forests, may be mentioned oak, elm, beech, ash, maple, birch, lime, sycamore, tamasack, cedar, walnut, and a variety of other

woods less generally known in England. The white oak of Canada, besides being cut into logs not greatly inferior in dimensions to those of white pine, serves also largely to supply staves for both the English and West Indian market. The tree called the sugar-maple is famous for the sap which it yields during early spring, from which excellent sugar is made in large quantities all over the country. Nearly 10,000,000 lb., or upwards of 500 tons, of this maple-sugar were produced in Canada in 1852. Maple groves, as collections of these trees are called, are therefore considered very valuable upon a Canadian farm. Of the ornamental woods of Canada, the bird's-eye and curled maple, and also the black walnut, deserve prominent notice. The black walnut furnishes a very beautiful wood for cabinet work.

The importance of these immense forests both to Canada and England, and even to the northern parts of the United States, may be said to be only now beginning to be fully appreciated. In 1852, according to the official returns, the products of the Canadian forests exported from the country were valued at L.1,350,000.[1] In 1851 it was computed that no less than 200,000 tons of sawn timber had been exported from Canada for the supply of the United States market on the Hudson river.[2] Of the various districts of Canada where the clearing or cutting down of the forests is being now carried on most extensively, the valley of the river Ottawa may be classed second to none. This particular branch of trade, known by the name of "lumbering," is in a great measure, as stated by the Earl of Elgin in his despatch of August 1853, carried on by persons of capital who employ large bodies of men at points far removed from markets, and who are therefore called upon to make considerable advances in providing food and necessaries, as well as in constructing slides and otherwise facilitating the passage of timber along the streams and rivers. "Many thousands of men," the Earl of Elgin goes on to observe, "are employed during the winter in these remote forests, preparing the timber which is transported during the summer in rafts, or, if sawn, in boats to Quebec when destined for England, and up the Richelieu river when intended for the United States." "It is a most interesting fact," continues his Lordship, "both in a moral and hygienic view, that for some years past intoxicating liquors have been rigorously excluded from almost all the shanties (as the dwellings of the lumbermen in these distant regions are styled); and that, notwithstanding the exposure of the men to cold during the winter, and wet in the spring, the result of the experiment has been entirely satisfactory." The prosecution of the lumbering trade has by many been considered hurtful to the interests of Canada. With regard to this interesting and important matter, Lord Elgin observes: "The bearing of the lumbering business on the settlement of the country is a point well worthy of notice. The farmer who undertakes to cultivate unreclaimed land in new countries generally finds that not only does every step of advance which he makes in the wilderness, by removing him from the centres of trade and civilization, enhance the cost of all he has to purchase, but that, moreover, it dimishes the value of what he has to sell. It is not so, however, with the farmer who follows in the wake of the lumbermen. He finds, on the contrary, in the wants of the latter a steady demand for all that he produces, at a price not only equal to that procurable in the ordinary marts, but increased by the cost of transport from them to the scene of the lumbering operations. This circumstance, no doubt, powerfully contributes to promote the settlement of those districts, and attracts population to the sections of the country which, in the absence of any such inducement, would probably remain for long periods uninhabited."

"This important region of the Ottawa," Lord Elgin states in the same despatch quoted above, "is probably doing more at the present time than any other single section of the province to enable Canada to enter the markets of the world as a purchaser." The river Ottawa, though it be but a tributary of the St Lawrence, "is one of the longest of the rivers that run uninterruptedly from its source to the embouchure within the dominions of the Queen. It drains an area of about 80,000 square miles, and receives, at various points in its course, the waters of streams, some of which equal in magnitude the chief rivers of Great Britain." The country of the Ottawa, Lord Elgin further observes, besides its wealth in timber and water power, and tracts of fertile soil, is believed to be also rich in minerals.

Animals.

The two most noted and mischievous animals of the Canadian forest are the bear and the wolf. Both of these, however, now are almost exclusively confined to the more remote and unsettled parts of the country, where their depredations in the farm-yards bordering on the woods give them occasional notoriety. It is very seldom that either animal is seen, and the hunters in search of farm-yard depredators may have sometimes to pursue their search in vain for days together. In order to exterminate wolves, a premium is paid by government for the head of each animal presented to a local magistrate. The beaver is now seldom found within reach of white settlements. Foxes, silver-gray, red, and black raccoons, otters, fitchets, martins, minks, and musk-rats still remain in diminished numbers. All of these are eagerly sought, chiefly by professional hunters, for the value of their furs, considerable quantities of which are yet exported from Canada. The official returns for 1851 show that furs and skins to the amount of L.28,000 colonial currency were exported during that year. Of this amount the greater proportion, namely, to the value of about L.20,000, went to the United States market.

Amongst the smaller animals of the woods, squirrels must not be omitted. The large black squirrels are shot in great numbers while scampering among the branches of the forest trees. The gray, the red, the ground or chipmonk, and flying squirrel, are the other varieties.

The most valuable game in Canada are the elk and the stag. The fine specimens of these noble animals, which are still found in many parts of the country in considerable numbers, occasionally afford excellent sport. Wild turkeys of large size were, several years ago, comparatively plentiful in the western parts of Canada; and are still found there, but in diminished numbers. Among other animals known in Canada, besides several species of grouse, may be mentioned the wood-cock, snipe, plover, and a species of hare. Pigeons are killed by thousands during the spring and autumn.

Of ducks there are many varieties, and several of them very beautiful. These are found in large numbers in the marshy parts of lakes and rivers. Wild swans are occasionally seen, and wild geese pretty frequently in certain parts of the country. Domestic fowls are abundant.

For the purpose of preventing the utter destruction of game in Canada, where all are allowed to indulge alike in the sport of the gun, an act was lately passed by the provincial legislature, preventing the shooting or killing any wild swan, wild goose, wild duck, teal widgeon, or snipe, between the 10th of May and the 15th of August.

The smaller kinds of birds are in many instances remarkable for beauty of plumage. In the list of these native and migratory, may be mentioned the jay, several species of woodpecker, the scarlet tanager, blue bird, the indigo bird, three species of blackbird, the American goldfinch

[1] Despatch from the Earl of Elgin. Quebec, August 16, 1853
[2] Report of Commissioners of Public Works, Quebec, August, 1852.

Canada. or flax bird, a robin, the meadow lark, several thrushes, a kingfisher, the swallow, and two or three very beautiful species of humming-birds. Several of these, although bearing the names of English birds, are specifically different from their namesakes in this country. The Canadian jay is about the size of the English bird, but the whole of the plumage is blue, and beautifully marked. The woodpeckers display gay plumage of scarlet, crimson, and green, and the largest of the species, known as the "cock of the woods," carries a tuft of scarlet feathers on his head. The Canadian robin is more than double the size of our little English favourite. As for the little humming-birds, nothing can exceed their rare beauty of plumage, tiny elegance of form, and rapid, graceful movements.

We now leave the land for the waters, to note some of the more remarkable of the finny tribe of the rivers and lakes. The sturgeon is caught in the Canadian waters, frequently weighing from 80 to 100 lb.; and the lake or salmon trout varies usually in size from 10 to 40 lb. Large quantities of the finest species of the lake trout family, known by the name of the siskawit, prized chiefly on account of its fatness, are annually caught by the fishermen of Lake Superior. This fish weighs from 5 to 20 lb. Very fine salmon are also abundant in the waters of the St Lawrence and the lakes. The smaller rivers and streams team with the speckled trout. Perhaps the chief favourites of the Canadian waters are the white fish and maskelonge. The white fish is much esteemed for delicacy and richness of flavour. Among other varieties of fish we may mention pike, pickerel, bass, perch, and herrings. The fisheries of Canada are constantly growing in importance from year to year. Many thousands of barrels of salmon, white fish, and herrings are annually exported at present, chiefly to the United States. Mackerel are also largely caught in the Gulf of St Lawrence. The parliamentary returns show that Canada produced in 1851 not less than 95,900 barrels of fish of various sorts. This quantity is exclusive of the Gaspé and Bonaventure fisheries in the Gulf of St Lawrence and Bay of Chaleurs, the southern shores of which bay are situated in the province of New Brunswick, and the northern in Canada. The Acadian French settled around the Bay of Chaleurs, employ themselves chiefly in fishing. There is a species of whale caught in the Gulf of St Lawrence by Gaspé fishermen, known by the name of "humpback," and which usually yield on an average three tons of oil each; some have been taken 70 feet long, which produced eight tons. In 1851 there were about 8500 gallons of oil exported from Canada, chiefly to England.[1]

Population.

1535 to 1759 The first settlement made by Europeans in Canada, as is well known, was by the French navigator Jacques Cartier in 1535; and, up to the memorable year 1759, the country continued to be a province of France. During the whole of that period the European population in Canada was comparatively insignificant. In 1759, when the country was under the last of the French governors, and Quebec surrendered to the forces of General Wolfe, the population of the colony amounted to 65,000. Canada was then known simply as the Province of Quebec, and the population was chiefly confined to the part of the country now known as Lower Canada.

The change of allegiance from one sovereign to another was rendered as easy as possible to the inhabitants by the lenient measures of England. Their French laws were allowed to remain unaltered. They were secured in the undisturbed possession of their lands under their ancient tenures, and in the free exercise of their religion. All ecclesiastical property was respected, and every concession was made by the British government in favour of the peculiar customs and manners of its new subjects. The French power on the continent of North America having been thus transferred and consolidated in the hands of the English, the country soon began to give token of advancement. As a reward to the army which had taken part in the conquest of the country, the provincial government was empowered to grant portions of land, varying from 50 acres up to 5000 acres, to each officer and soldier. Many old soldiers from the United States too, after this, settled along the banks of the St Lawrence. To these, considerable additions were made about the period of the United States' Declaration of Independence, as many of the defeated royalists settled in the British province of Canada at the close of the revolutionary struggle. A stimulus having now been given to English enterprise in the newly-acquired colony, the population in 1784 had risen to 113,000—being an increase since 1759, when the province was transferred to England, of 48,000.

Canada. 1759 to 1784

For a period of many years after Canada had come into the possession of England, and Lower Canada had begun to experience the stimulus of new enterprise and an increased population, the large portion of country westward, lying along the great lakes, now known as Upper Canada, and in its extent nearly double the size of England, was one vast forest. Only a few French immigrants had placed themselves near the foot of Lake Ontario, and on the shores of the Detroit river, previous to 1770. The only other inhabitants were the native Indians, to whom this forest with its occasional patch of plain by lake or river side, was one great hunting ground. Several years later, numbers of families who had resided in the now United States, and who, at the disruption with England, refused to transfer their allegiance to the independent government, came over into Canada, and settled on the borders of the lakes. These individuals, the pioneer settlers of Upper Canada, were, and have since been, termed United Empire Loyalists.

In 1791, when, by an act of the imperial parliament, the colony received a constitution, and was divided into the two provinces of Upper and Lower Canada, with separate legislatures, the amount of the white population in Upper Canada was estimated at less than 50,000. In 1811, twenty years later, it had only increased to about 77,000. Very shortly afterwards, and especially upon the conclusion of peace between Britain and the United States, in 1814, population rapidly increased in Upper Canada. In 1825, when the advantages of the colony to the home population began to attract attention, the colonists of Upper Canada had increased to 158,000. With an increasing emigration, the country now rapidly swelled the number of its inhabitants. In 1830 they amounted to 210,000; and, in 1834, the numbers exceeded 320,000: the increase within the nine years previous to 1834, namely, from 1825, having been not less than 162,000. The country during that period had indeed doubled its population. During the first five years of this period, from 1825 to 1830, the emigration to British America was proceeding very steadily at about 12,000 a-year. In 1830 this flow of emigration increased to 30,000, in 1831 it rose to 58,000, and in 1832 it reached over 66,000. From this period, during the political disturbances in Canada, the number of emigrants from Britain gradually declined. Since then, however, an increasing flow of prosperity visited the country. The official returns show that in one year, that of 1847, the emigration to British America had exceeded 109,000. In 1842, the population of Upper Canada was 486,000; showing an increase since 1830 of 276,000—a period of twelve years, and including the season of political disturbances. The population, in short, within that period, had considerably more than doubled. The census of 1848 shows the amount of population of Upper Canada to have reached 723,000—an increase within the six years of over 237,000. The last census of 1852 shows the population of this rapidly growing portion of Canada to have reached very nearly 1,000,000—the precise official return being 952,004. Comparing this with the return of 1842, we arrive at the gratifying result that the population of Upper Canada has nearly doubled itself within these last ten years.

1791 to 1834

To convey as clearly as possible an idea of the remarkable progress of Upper Canada in respect of population, we here present the results from official documents in tabular form. We shall begin with the period when Upper Canada was erected into a separate province, namely—

[1] *Views of Canada; Smith's Canadian Gazetteer; Parliamentary Returns*, &c.

Canada.

Year.	Population.	Increase.
In 1791	50,000	
1811	77,000	In 20 years, 27,000
1825	158,027	14 .. 81,027
1830	210,437	6 ... 52,410
1834	320,693	4 ... 110,256
1842	486,055	8 ... 165,362
1848	723,392	6 ... 237,337
1852	952,004	4 ... 228,632

The increase of wealth too in Upper Canada, especially of late years, has not been less remarkable than this rapid increase of population. Previous to 1850, the cultivated land of Upper Canada was valued, for the purpose of local assessment, at 20s. currency, or about 16s. sterling per acre; and uncultivated land at 4s. currency, or about 3s. 3d. sterling per acre. The total amount of assessable property in Upper Canada, according to this estimated value, was—

Year.	Property. £ currency.	Increase. £ currency.
In 1830	1,854,965	
1835	3,407,618	In 5 years, 1,552,653
1840	4,608,843	5 ... 1,201,225
1845	6,393,630	5 ... 2,784,787

These estimates of the value of cultivated and uncultivated land were, however, very considerably under the true value. The board of registration and statistics in Canada report, in 1849, the estimated value of cultivated land in Upper Canada to be 70s. 10d. currency per acre, and uncultivated land 29s. 2d. currency per acre. An act was therefore passed in 1850 requiring property to be assessed at real value. The Earl of Elgin, in his exceedingly interesting despatch dated Quebec, December, 1852, presents statements of the more just valuations of 1851 and 1852—which his lordship observes, though not strictly official, he believes to be tolerably correct.

The statements of the governor-general, published in the above mentioned despatch, have been proved to be very considerably within the actual official return. An official statement received from the government of Canada,[1] dated within a month from the time of writing this article, gives the total value of assessable property in Upper Canada—

Year.	Property. £ currency.	Increase. £ currency. In one year.
1851	44,106,817	
1852	45,863,383	1,756,566
1853	49,627,392	3,763,909

The Earl of Elgin's moderate estimates of assessable property in Upper Canada for 1851 and 1852 were fully more than L.8,000,000 less each year than the above actual official returns. The farmers, in order to avoid local taxation, are understood to keep down their returns at the lowest possible point. The real value of assessable property in Upper Canada at present is believed to be not less than L.150,000,000.

Lower Canada, as is known, is inhabited chiefly by French Canadians, speaking their native language, retaining almost entirely their ancient laws, manners, and religion, following rude modes of agriculture, and generally averse to improvement. For these and other reasons, the country has not made the same degree of progress as Upper Canada. Although a much older settlement, the old French portion of the province was, by the census of 1852, somewhat behind Upper Canada in amount of population. Upper Canada in 1852, as we have noticed, possessed a population of 952,004, while the population of Lower Canada in the same year did not exceed 890,201. Of this amount of population in Lower Canada 669,528 were of French origin, and the remaining 220,733 were composed of emigrants from Great Britain and other countries, and of Canadians not of French origin. In Upper Canada only 26,417 of the entire population were of French origin, the remaining 925,587 being composed of emigrants from Great Britain and other countries, and of Canadians not of French origin.

Lower Canada, however, has enjoyed important advantages which have enabled it, in spite of its drawbacks in respect of population, and perhaps of climate, to keep pace with the upper division of the country. Being much nearer to the sea-board of the Gulf of St Lawrence, it has been enabled to land at less cost upon the large fertile tracts it possesses numbers of enterprising emigrants. Besides, it has hitherto monopolized the navigation of our ocean vessels, as their ascent of the St Lawrence practically terminates at Montreal, and thus two large commercial cities have risen into importance, and the enterprise and wealth of extensive mercantile houses have sent abroad their influences more or less all over the country.

Canada.

The largest increase of prosperity in Lower Canada has shown itself in the Eastern Township, where the lands have been held exempt by the English government from the feudal tenure, and in the cities of Quebec and Montreal, indebted for their support to the trade of the upper and surrounding country and to the commerce of England and the United States. In 1827 these cities had each a population of about 27,000; and by the census of 1852 Quebec shows a population of 42,052, and Montreal of 57,785. Besides these cities of Quebec and Montreal, there are a number of small towns and villages scattered over Lower Canada. The largest of these are, Three Rivers, Sorel, St Hyacinthe, St John's, and Sherbrooke. The population of Three Rivers in 1852 was nearly 5000, that of Sherbrooke 3000, and those of Sorel, St Hyacinthe, and St John's, somewhat over 3000.

Towns.

The growth of the towns of Upper Canada has been very remarkable. Toronto, now a flourishing city upon the shores of Lake Ontario, contains by the census of 1852 a population of 30,775. Its population just now may be estimated at fully 40,000, and the value of its assessed property may be stated to be not far short of L.5,000,000.[2] In 1817 Little York, as Toronto was then called, contained only 1200 inhabitants, and so lately as 1826 the number had only increased to 1677. In 1830 the population had increased to 2860, and in 1836 it had risen to 10,000. In 1842 the population of the town was 15,336, in 1845 19,706, in 1848 23,500, in 1852 the number had reached 30,775, and now, in 1854, we estimate its population at fully 40,000. It has thus, we perceive, quite doubled its population within twenty years.

Amongst the other principal towns of Upper Canada are Hamilton, Kingston, London, and Bytown. The first named of these, Hamilton, which is situated at the extreme head of Lake Ontario, on a very spacious and beautiful bay, had in 1852 a population of 14,112. Its present population (1854) may be estimated at nearly 20,000, and the amount of its assessable property at nearly L.3,000,000. Hamilton, which had recently been raised to the dignity of a city, enjoys many advantages, and, like Toronto, has grown rapidly. In 1844 it had only about 5000 inhabitants, so that since then it has nearly tripled its population. Kingston, the third city of Upper Canada as respects population, is situated at the extreme foot of Lake Ontario, and contained in 1852 11,585 inhabitants. London and Bytown had each in 1852 populations of over 7000, and both towns are growing rapidly. London is situated in the heart of one of the finest agricultural districts in Upper Canada, in the centre of the great peninsula situated between the lakes Ontario, Erie, and Huron, and on the main trunk line of railway passing through Canada from some distance below Quebec, and from the Atlantic sea-board at Portland, Maine, to the foot of Lake Huron. This town of London, with its population in 1852 of 7000, and now at least 10,000, had not a single house until 1827. Bytown, on the river Ottawa, is at present chiefly indebted for its importance perhaps to the extensive lumbering trade carried on along the shores of that great river. It is very agreeably situated upon a high bank of the river, about 180 miles above Montreal.

Besides those larger towns of Upper Canada, there are other prosperous and growing towns, such as Belleville, St Catherines, Brantford, Cobourg, Dundas, Niagara, Brockville, Port Hope, Prescott, Galt, Peterbro', Woodstock, and Chatham. The two first-named of these, Belleville and St Catherines, possessed each a population of over 4000. The one is situated on the bay of Quinté, an inlet of Lake Ontario; the other on the Welland canal, which connects the navigation of Lake Ontario and Erie, and thus obviates the interruption caused by the Falls of Niagara. The rest of the places named have each a population from 2000 and upwards to nearly 4000, and the whole of

[1] Statement showing the assessable value of property within the several counties and cities in Canada West, in 1851, 1852, and 1853. Inspector-General's Office, Quebec, March 23, 1854.

[2] The assessed value of property in Toronto in 1853 was L.4,216,666.—Statement, Inspector-General's Office, Quebec, March 23, 1854.

Canada.

them are steadily growing with the rising interests of the country. They are all very favourably situated, commanding the resources of fertile and prosperous districts, and many of them are ports possessing either navigable rivers, or the more direct communication of the shores of the great lakes.

The area of Great Britain in statute acres is 57,624,377, while that of Canada is 155,188,425, Canada being thus not far from three times the size of Great Britain; and it is believed we are safe in estimating the proportion of cultivable land to be much larger in Canada than Britain. The proportion of land to each person in Canada at present is nearly 69 acres, while in Great Britain the proportion to each person is a fraction over two acres. During the last 50 years, in which time 10,000,000 of people have been added to the British population, the proportion of land to each person had decreased from five to two acres. The number of persons to a square mile in Canada is only eight, while in Great Britain the census of 1851 gave 233 persons to a square mile.

When we consider that the emigration from Great Britain and Ireland amounted in 1852 to 368,764, which is at the rate of 1000 persons a-day sailing from the United Kingdom, we can readily account for the wonderfully rapid growth of Canada, especially of late years. While our home population thus increases notwithstanding this large emigration, and the proportion of land to each person is thus continually diminishing, Canada will no doubt continue much more rapidly to increase, both in numbers and prosperity. America and Australia divide between them the great outflow of our population. The cheap and fertile lands of Canada will continue more strongly to invite the enterprising and industrious of all classes; and while its towns grow as they are now doing, adding to their material prosperity a larger increase of all the comforts and luxuries of home cities, continual inducements will be held out to gentlemen of moderate fortunes and large families, and also to young men of education who are now crowding the professions in England.[1]

Situated so near to Europe, and offering so inexhaustible supplies of fertile and cheap land, with light taxes and a liberal government, we are prepared to find in Canada people from various countries. The subjoined analysis is from the tables of the census of Upper Canada of 1852.

Population of Upper Canada, 1852,		952,004
Natives of—		
England and Wales,	82,699	
Scotland,	75,811	
Ireland,	176,267	
Canada, French origin,	26,417	
Canada, not of French origin,	526,093	
United States,	43,732	
Nova Scotia and Prince Edward Island,	3,785	
New Brunswick,	2,634	
Germany and Holland,	9,957	
France and Belgium,	1,007	
Jersey and other British Islands,	1,351	
Various other countries,	2,251	
		952,004

The county of Upper Canada containing the largest number of Scotchmen is Middlesex. The total population of this county, situated in the heart of the great fertile peninsula between the lakes Erie, Ontario, and Huron, was in 1852 32,864, of which number 4762 were natives of Scotland, and 3171 natives of England and Wales. The Scotch settlements in the county of Middlesex, particularly in the township of Westminster and around the town of London, have been remarkably prosperous.

Many of the persons composing these settlements emigrated to Canada in order to escape the almost certain privations which presented themselves in this country to the worst-paid classes of workmen, such as the hand-loom weavers of the past generation. These men, in most instances, are now in the enjoyment of a competent independence in their well-cleared farms, of which they are the proprietors. Their abundance, it is true, may be in a manner rude enough to more cultivated tastes, but they seem quite calculated to confer contentment and happiness upon a class of persons to whom industrious toil is an enjoyment, when it can secure to them amply, even to overflowing, all the necessaries, and many of the comforts of life suited to their own simple and unambitious desires.[2] The success of Scotchmen in Canada is indeed particularly proverbial there; and it is not too much to say, that the decided majority of successful tradesmen in the towns of both Upper and Lower Canada, and of the most eminent merchants of the country, are either Scotchmen or descendants of Scotchmen.

Canada.

The county of Upper Canada containing the largest number of persons from England and Wales is York, on the shores of Lake Ontario, in which the city of Toronto is situated. In this county of York, with its total population of 48,944, there were 7749 natives of England and Wales; 3111 natives of Scotland; 9241 natives of Ireland; 25,961 native Canadians not of French origin, and 2049 natives of the United States. The city of Toronto, with its population of 30,775, numbered 4958 natives of England and Wales; 2169 natives of Scotland; 11,305 natives of Ireland; 9956 native Canadians not of French origin, and 1405 natives of the United States. These 3454 Americans residing in the county of York in Upper Canada, including the city of Toronto, so near to their own shores of the United States, is a fact not to be overlooked, testifying as it does so significantly in favour of Canada.

The county of Upper Canada containing the largest number of Irishmen is the same county, York, which contains also the largest number of Englishmen—there being in that county, as already stated, above 9241 natives of Ireland. And the city of Toronto, as we have also observed, with its population of 30,775 in 1852, included 11,305 natives of Ireland.

"Instead of my being astonished," writes an Irish gentleman from Canada to a friend in Dublin, "at the immense amount of emigration that has taken place from Ireland during the last few years, my surprise is that the whole of its peasant population has not already come, either to this country or the United States. During the few weeks that have elapsed since I landed, I have travelled 1850 miles by rail and steamboat; and although I am told that I have not as yet visited by any means the best portion of Canada (Upper or Western Canada), I have seen quite enough to convince me of its inexhaustible resources, and the glorious field that it is for the Irish people. The moment the vessel arrives at Quebec (the port to which all emigrants for Canada should come), the men are immediately engaged, either for the railroads, or for the government provincial works now in course of construction. The wages for labourers are four shillings British per day; they can be most comfortably boarded (with meat twice a-day) for about one shilling, and allowing one shilling more for other expenses, it leaves two shillings per day of savings. Then again, on the Ottawa river, one of the great sources of the inexhaustible supply of Canadian timber, 'lumbermen' earn at least one dollar per day; and, as they advance in skill and experience, their wages rise to a dollar and a half and two dollars.

"In the immediate vicinity of this river and its tributaries, throughout their entire extent, is magnificent agricultural land. The farmers, four-fifths of whom are Irishmen, or sons of Irishmen, who came to this country as lumberers, and purchased farms with their savings, sell all their produce without ever going to market as the master lumberers purchase it to feed the men in their employ. I am assured that Irishmen make better lumberers than the natives of any other country; for it appears that the good and abundant food they begin eating from the moment they arrive here expands, not only the muscular frame, but also the intellect; and no one who has not seen the contrast between the down-cast, ill-fed, and ragged Irish peasant in his own country, and the same man after even a few months' residence in these provinces, could believe in its completeness. A few days ago, the driver of a stage-coach, between two portions of the Ottawa, unnavigable for steam vessels, but which the government is now obviating, told me that he came to this district in 1841, with one dollar in his pocket; and I learned from a gentleman with whom he had originally worked as a common labourer when he first came out, that he is now worth L.1000 and has a capital farm. On my expressing surprise that a man like him could have an average of savings of L.80 a-year since he arrived, I was assured that so far from this being a solitary case, there was hardly an Irishman who is industrious and temperate (the latter is just as necessary as the former quality) that is not more or less in the same position. For myself, I can only say, that I have not seen an Irishman since my arrival who has not an air of comfort, cleanliness, and independence about him."[3]

The number of coloured persons of African descent in Upper Canada, included in the abstract of the census, but not classed as such, was computed in 1852 to be about 8000. Since 1852 this description of the population has, it is believed, very largely increased; Canada offering so freely to these persecuted victims of slavery a

Canada. safe and welcome refuge. These people are usually employed in the towns as waiters in hotels, as barbers, and in the performance of the most burdensome and menial descriptions of labour, such as cutting and preparing wood for fuel. Large numbers of them are employed upon the extensive railway works now going forward in Canada, and earn liberal wages. They have as labourers great powers of endurance; and when their dispositions have not been soured by ill usage, they are most generally civil and attached servants. There is also a small proportion of educated coloured persons in Canada, whose qualifications and general conduct have assisted much to remove the prejudices against their unfortunate race existing more or less all over America.

Indians. With regard to the native Indians of Canada, it may convey some idea of the thinning out of these children of the forest, to observe, that it is only on comparatively rare occasions that the white settler meets with a straggling few, or single family or individual. There are various small settlements of them scattered in different parts of Canada, where, under the civilizing influences of missionaries and school teachers, they have adopted, with some exceptions, improved habits of life, subversive of their former wild and roving dispositions. The principal Indian settlements in Canada are, Manitoulin island, near the northern shore of lake Huron; a small settlement near the head of the river St Clair; and one on Walpole island, at the foot of the same river; another on a retired part of the banks of the river Thames, in the London district; also along the banks of the Grand river, in the Niagara district; in one or two localities along the shore of lake Ontario; also on the banks of the St Lawrence, between Kingston and Montreal; in the vicinity of Quebec; and towards the mouth of the St Lawrence, around a part of the shore of the gulf. These localities on which they are settled are comparatively limited in extent, and apart from the white settlements. The Indians of the present day are almost, without exception, civil and quiet in their manners, as well as generally improved in many of their habits. They are, nevertheless, greatly addicted to indolence and intoxication. The Indians in Upper Canada have been chiefly indebted to the body of Wesleyans and to the Church of England for their missionaries; and those of Lower Canada are, perhaps without exception, brought up in the faith of the Romish Church, under the teachings of the French Canadian clergy.

The greater number of the Indians in Canada are almost directly under the care of the government. There is a special government department devoted to their affairs, the chief superintendent of which is the governor-general's secretary. There are several assistant superintendents who watch over their particular interests, and they have also government missionaries and schoolmasters.

Besides the settlements alluded to around the occupied parts of Canada, there are the Indians mentioned in the report of Lord Elgin, in the great forests along the shores of Lake Superior, and other distant points, comparatively speaking, beyond the limits of civilization. These, though much tamed by civilizing influences, extending even to them in these retreats, are yet engaged, in a great measure, in their primeval pursuits of hunting and fishing. The Hudson's Bay Company afford employment to numbers in the collection of their furs. The stations of the Company, throughout the remote regions in which they are situated, distribute European goods in exchange for the produce of the hunt; and the Company's interests are exercised paternally, in some measure, over these far-scattered inhabitants of the forest.

The Indians residing in British America are much attached to the crown of England, and not unfrequently refer to their "Great Mother across the Great Waters," with feelings of proud gratification. Major Sprague, of the United States, is reported to have related the following anecdote upon the occasion of celebrating St George's day at New York in 1853. "Some years ago," said Major Sprague, "I was engaged in removing some Indians beyond the Mississippi, and one day when encamped I saw a party approaching me. I took my glass and found they were Indians. I sent out an Indian with the *Stars and Stripes* on a flag, and the leader of the Indians immediately displayed the RED CROSS OF ST GEORGE! I wanted him to exchange flags, but the savage would not; for, said he,—'I dwell near the Hudson Bay Company, and they gave me this flag, and they told me that it came from my Great Mother across the Great Waters, and would protect me and my wife and children, wherever we might go. I have found it to be so as the White Man said, and *I will never part with it!*'"

Many of the Indian women employ much of their time in fanciful bead-worked articles, such as moccasins, and various kinds of small bags, made from prepared deer skin and the pliant inner bark of trees, which they dispose of to the white inhabitants as Indian curiosities. They make also useful as well as ornamental baskets from the prepared bark. The small and very prettily situated Indian village of Lorette, in the neighbourhood of Quebec, and not many miles from the falls of Montmorency, is much noted for this description of Indian industry.

Cultivated Land and Agricultural Products. Canada.

The number of persons occupying lands in Canada, according to the census of 1852, was 194,309. Of whom there were holding—

10 acres and under	23,237
10 to 20	4,590
20 to 50	35,876
50 to 100	85,812
100 to 200	37,029
above 200	7,765
	194,309

The number of occupiers of land in Upper Canada exceeds the number in Lower Canada by 5411. The greatest number of small holders of 10 acres and under are, in Lower Canada, owing, no doubt, to the continual subdivision of lands going on among families, caused by the working of the French law of inheritance. The number of holders of above 200 acres is also larger in Lower Canada, which is accounted for by the existence of the large original grants under the old French titles, known as seigniories. Almost quite the one-half of the farms of Upper Canada are of the medium-sized classification; there being of the 99,860 occupiers of land in Upper Canada, 48,027 holding from 50 to 100 acres.

The number of acres held by these 194,309 occupiers of land in Canada is 17,937,148; 9,823,233 acres of which are held in Upper Canada. The number of acres under cultivation in Canada in 1852 was 7,303,241, the greater proportion of this cultivated land being in the upper provinces. The increasing quantity of cultivated land in Upper Canada is another of the gratifying proofs of the substantial progress of the country; and this increase of the area of cultivation keeps full pace with the increase of population. In 1842 the population of Upper Canada, amounting to 486,055, possessed 1,927,816 acres of land under cultivation; and in 1852 the population, which had increased to 952,004, possessed an area under cultivation of 3,697,724 acres.

The proportion of occupied lands in Canada under cultivation, under crops, pasture, and used as gardens and orchards, and also in forest or wild state, were as follows:—

	Acres.
Land under crops	4,347,539
...... pasture	2,870,004
...... gardens	85,698
...... cultivation	7,303,241
...... forest or wild	10,633,907
Total occupied land in Canada	17,937,148

The distribution of the land under crops, and the produce of these crops respectively, were—

Under.	Acres.	Produce in Bushels.
Wheat	1,209,226	15,768,720
Oats	1,012,106	20,161,438
Pease	357,301	4,055,584
Potatoes	150,916	9,443,586
Buckwheat	96,046	1,169,801
Maize	93,240	2,096,800
Rye	84,975	821,094
Barley	72,843	1,294,501
Turnips	21,032	4,014,851
Fallow and other crops,	1,249,854	...
Total land under crops,	4,347,539	
Total produce of above specified crops,		58,826,375

Besides these amounts of specified produce from these 4,347,539 acres of land under crops, the Canadian farmers possessed other crops, such as hay, clover, and grass seeds, carrots, mangel-wurtzel, beans, hops, flax, hemp, and tobacco. The quantity of tobacco produced in Canada in 1852, amounted to 1,253,128 lb.; of this, 764,476 lb. were the produce of Upper Canada; and the greater portion of which was grown along the shores of the upper part of Lake Erie, and of the river Detroit, where the soil and climate seem best adapted for this description of crop, and where the farmers in those parts have had the best opportunities of receiving the services of the coloured or runaway slave population of the United States, who have been

Canada.

accustomed to the management of such produce in the tobacco plantations of the south. The produce in tobacco of the two counties of Kent and Essex alone, situated in this south-western point of Canada, amounted in 1852 to 760,300 lb.

Hemp.

The growth of hemp in Canada assumes a position of great national importance at the present time when British supplies have been so seriously checked by the war with Russia. The important towns upon the east coast of Scotland, which are the chief seats of the flax trade, have suffered severely by the check received by our being so dependent upon Russia for this great staple of a growing branch of our national manufactures. Were our own dominions in North America to supply hemp for our manufactures in future, instead of our being, as hitherto, so wholly dependent upon Russia for such supply, the change would be attended with signal advantage to both countries.

The elaborate work of the late Colonel Bouchette on British America affords a good deal of information in regard to the capabilities of Canada for the growth of hemp, and explains the causes of the comparative failure of these efforts made many years ago to introduce the cultivation of this important staple upon an extensive scale into Canada.[1] Colonel Bouchette, as is known, was surveyor-general of Lower Canada, and a corresponding member of the Society of Arts in London; and he was therefore enabled, both from his official position and general acquirements, to furnish facts and opinions of unquestionable value bearing upon the subject in question. According to calculations of Colonel Bouchette, the cost of one ton of merchantable hemp landed in England would be not quite L.21 sterling. The mean price of Russian hemp in the English market at that time was L.40, 15s. sterling.

The American navy use at present large quantities of native-grown hemp. Mr W. B. Shubrich, chief of the bureau of construction, navy department, United States, in a report to the secretary of the navy, recommends greater attention to the detail of cultivation, curing, and packing native-grown hemp, "which, in the opinion of the bureau, would be found to be very beneficial in effect, and in the course of time *make it altogether independent of a foreign market* for a material so important for naval purposes." Mr Gardiner, superintendent of the ropework of the United States navy-yard at Memphis, in a report of his department, further substantiates these views, concluding that with proper care "American hemp may (*as experiment has proved*) *be made to equal, if not to excel, any foreign importation*."[2]

The quantity of hemp and flax produced in Canada, taken together, as officially returned, amounted in 1852 to 1,917,666 lb., being above 800 tons. The value placed upon this by the government board of registration and statistics in Canada is 3d currency, or L.28 currency per ton, which reduced to sterling is L.23, 3s. The total value of the hemp and flax grown in Canada in 1852, was therefore, according to his official valuation, L.23,971 provincial currency; and very nearly the whole was the growth of Lower Canada.

We now subjoin in tabular form the official amounts of the produce for 1852, and respective values of seven articles, which, added to the great staples of grain crops produced in Canada, assist very materially to swell the value of the aggregated productions of the country.

	Lb.		Value. £ currency.
Tobacco	1,253,128	at 0s. 6d.	31,328
Wool..................	4,130,740	at 2s. 0d.	413,073
Maple sugar	9,772,199	at 0s. 4d.	162,870
Hops	224,222	at 1s. 0d.	11,210
Flax and Hemp	1,917,666	at 0s. 3½d.	23,971
Hay..................... (tons)	1,647,435	at 40s.	3,294,870
Clover and grass seeds (bushels)	61,381	at 10s.	30,690
Total value of above seven productions,			L.3,968,012

The increased cultivation of wheat, especially in Upper Canada, is particularly gratifying; and, taken in connection with the rapid increase in the amount of cultivated land, and of the various descriptions of other produce, we are enabled thus the more readily to account for the present prosperous condition of the entire colony, and to look forward upon its important prospects with the greatest confidence. While the farmers of Upper Canada have been increasing in numbers, they have, at the same time, as proved by the results of the last census, been advancing in skill and intelligence. While the average produce of wheat in Lower Canada in 1852 was about 7¼th bushels per acre, the average produce in Upper Canada was about 15 bushels per acre—a remarkable contrast between the farmers of Upper Canada and those of the lower province, the majority of whom are still the same Norman French who settled on the banks of the St Lawrence above a hundred years ago, clinging still to their ancient traditional prejudices in their laws, customs, manners, and religion, with the increasing tenacity of an uneducated and unprogressive people.

Canada.

Wheat.

This contrast in regard to the produce of wheat between the upper and lower province is nearly quite as complete and striking in almost every description of crops. Thus the average produce per acre of oats in Upper Canada is 26½ bushels per acre, while in Lower Canada it is 15 bushels per acre. Barley in Upper Canada yields, on an average, 21 bushels per acre, while in Lower Canada 15 bushels is the average, being the same as oats. Pease on the average in Upper Canada yields 15 bushels, while in Lower Canada pease yields not quite 7½ bushels. Indian corn yields in Upper Canada 24 bushels, while in Lower Canada the same crop yields 17½ bushels. Turnips yield, on the average, in the upper province 212¾ bushels per acre, while in the lower province this description of crop yields precisely, on the average, 95 bushels per acre. In the crop of potatoes alone do the provinces approach in their respective averages per acre. The produce per acre of potatoes in Upper Canada is 64 bushels; Lower Canada 60 bushels.

The average produce of wheat per acre has increased, in Upper Canada at least, since 1847. In 1847 the average produce of wheat in the upper province was 13 bushels, in 1849 13½ bushels, and in 1852 15 bushels. The quantity of wheat produced altogether in the whole of Canada has increased remarkably within the last ten years. Whilst the growth of wheat in the United States during the last ten years has increased about 48 per cent., the growth of wheat in Canada during the same period has increased upwards of 400 per cent.[3] And Upper Canada is not much assisted by the lower province in this increased production of wheat; for, whilst the produce of wheat for all Canada in 1852 amounted to 15,768,720 bushels, Lower Canada only contributed as its share of this amount 3,075,858 bushels; thus showing Upper Canada to have produced the large amount of 12,693,853 bushels of wheat. The total value of the crop of wheat in Canada for 1852 was L.3,231,190; the value of that produced in Upper Canada alone being L.2,535,121.[3]

The particular localities of Upper Canada presenting the largest returns of wheat per acre, were the township of Equesing in the county of Halton, and that of Scarborough in the county of York; both townships near the head of Lake Ontario, Scarborough being situated a little east, and Equesing somewhat west of Toronto. The return for Equesing gave 26 bushels of wheat to the acre, and Scarborough 24 bushels. Comparing Canada with the United States as wheat-growing countries, it is found that the population of Canada, reaching at present to one-thirteenth part of the population of the United States, and the area of Canada being in square miles, exclusive of the territories, equal to one-sixth of that country, the growth of wheat in Canada now reaches very nearly to one-sixth of the growth of the whole United States and territories.

[1] Bouchette's *British Dominions in North America*, vol. i., p. 470–78.

[2] *Report of the Secretary of the Navy*, December 4, 1852, included in the *Message from the President of the United States to the two Houses of Congress*, December 6, 1852.

[3] The above and all other statements in regard to these statistics of population and agriculture are founded on the authority of the *First Report of the Secretary of the Board of Registration and Statistics of the Census of the Canadas for* 1851–2; printed by order of the Board, Quebec, 1853. Also, *Returns by the Secretary of the Board of Registration and Statistics*, accompanying the Earl of Elgin's despatch, dated Quebec, December 22, 1852. The writer has also before him official statements received from the government of Canada, dated Quebec, March 25, 1854.

Canada.

Upper Canada produces $13\frac{1}{4}$ bushels of wheat to each individual of its population; and calculating one-half of that quantity to be sufficient for home consumption in the shape of food and seed, we have the result that Upper Canada is able already to dispose of about 6,000,000 bushels of its annual crop of wheat. Again, comparing Upper Canada with one of the best wheat-growing portions of the United States, it is found that it produces 6 bushels more wheat to each individual of the population than the state of Ohio. The total value of grain and other produce in Canada in 1852 was estimated by the official census report at L.10,059,421.

Live Stock.

Canada possesses large numbers of live stock. The number of cattle, including oxen, milch cows, and calves, amounted in 1852 to 1,332,544 This number included 591,438 milch cows. The number of horses amounted to 439,377, and of sheep, 1,597,849. The increase of sheep and improvement in the weight of the fleece are gratifying proofs of the advancing prosperity of the country. The total value of live stock in 1852 was estimated at L.10,947,537.

The value of occupied land in Upper Canada, including the cultivated and uncultivated taken together, is set down in the official report on the census at 74s. 7d currency per acre, and in Lower Canada at 72s. per acre. In Upper Canada farms partly cultivated may not unfrequently be procured at prices ranging from L.3, 10s. to L.7, 10s an acre. The value of cultivated land in Lower Canada may be said to range from 15s. to L.7, 10s. an acre. The government lands of Lower Canada may be purchased from 2s. to 4s. per acre, and those of Upper Canada at 8s. per acre. In both provinces there are lands which the colonial government will allot, without purchase, to the extent of 50 acres, to individuals of 21 years of age and upwards, who have not previously received a grant of land from government, on condition that they satisfy the commissioner or his agent that they can support themselves until a crop can be raised. The lands of the Canada Company in Upper Canada range from 12s. to 30s. per acre, and those of the British American Land Company in Lower Canada from 10s. to 15s per acre.[1] Both of these companies also dispose of their lands on leases for a limited term of years, the yearly payment amounting to merely interest at six per cent. upon the value of the land. This arrangement is made with a view to the parties becoming purchasers of such lands. The Canada Company, as is known, was incorporated in 1826, and the British American Land Company in 1834; and both of these companies have contributed much to diffuse a better knowledge of the resources of Canada throughout this country.

The average value of agricultural products in Canada, as estimated in the official report on the census for 1852, was, for wheat 4s., barley 3s., pease 3s., Indian corn 2s. 6d., buckwheat 2s., and oats 1s. per bushel. Hay was valued at 40s. per ton, grass seed 10s. per bushel; hemp and flax 3d., tobacco 6d., hops 1s., and wool 2s. per lb., butter $7\frac{1}{2}$d.; cheese 5d., and maple sugar 5d. per lb.

Having given these details in relation to a country the interest in which has of late years largely increased in Britain, we close this part of the subject with an extract from an official report of the commissioners of emigration. The passage is from the despatch of the government emigration agent, A. C. Buchanan, Esq., stationed at Quebec, addressed to the commissioners, on the prospects of emigrants to Canada:—"The prospects and demands for labour are most satisfactory. The immense railway system undertaken by the provinces will greatly stimulate general prosperity, involving, as it will, the introduction and expenditure of a large amount of capital, which will secure steady and profitable employment for the labouring classes for several years to come; so that Canada never presented a more favourable opening for the reception of all classes of her Majesty's subjects, or such others as seek a comfortable home. The demand for labour of every kind is on the increase. The wages paid for unskilled labour are 4s. sterling per day." Mr Hawke, the emigration agent for Western Canada, speaks in similar terms:—"I have," he says, "conversed with many intelligent persons on the subject, and they are of opinion that able-bodied, unskilled labourers will be able to command a dollar a-day. Agricultural labourers must either get equal wages, or the farmers will not be able to retain them in their service. As the extensive railway works will not be completed for several years, and as such a large outlay of money will stimulate every other branch of business, I do not think it will be possible to overstock the labour market for many years to come; in fact, the prospects before us are of the most cheering description, for capitalists, merchants, mechanics, farm-servants, and common labourers, may safely calculate on finding in Canada an abundant demand for skill, capital, and labour, to a profitable, as well as to an almost unlimited, extent."

Canada.

Trade of Canada.

The trade of Canada at a period not very distant was confined chiefly to the exportation of furs, seal-oil, and timber, little exceeding L.100,000 annually. Prior to the year 1759, when the country, with its population of 65,000 inhabitants, was transferred from the government of France to that of England, the precise amount of its annual exports was L.115,415. The principal trade was furs, in pursuit of which the great forests were traversed by bands of resolute adventurers. A few ships were occasionally built. Agriculture was neglected, if not actually despised.

Upon the conquest of the country, however, by England, the cultivation of the soil attracted the attention of the settlers, and the germs of a trade sprung up which has now grown to be one of real magnitude and importance. In 1769 the exports in furs, oil, fish, &c., amounted to L.355,000, and the imports in British manufactured goods and West India produce, reached L.273,400. This trade employed 70 vessels; about 12 vessels were at this period engaged in the fisheries of the St Lawrence, and about 6 were sent to the West Indies.

In 1799 and the three following years we find a comparatively large exportation of grain taking place. In 1802, 1,010,000 bushels of wheat, 38,000 barrels of flour, and 32,000 cwts. of biscuit, were sent abroad. The number of vessels at this period engaged in the trade of the colony, was 211, the aggregate burden of which amounted to 36,000 tons. In 1809 the first steamboat appeared in the harbour of Quebec.

In 1809, 1810, and 1812, the trade of Canada, benefiting by increased duties levied upon Baltic timber imported into Britain, seems to have been comparatively active. In the first of these years 440 vessels, having an aggregate tonnage of 87,825 tons, arrived at Quebec. In 1810 as many as 635 vessels arrived in the St Lawrence, with an aggregate tonnage of 138,057 tons; and in the same year 26 vessels, having a tonnage of 5836 tons, were built in the province. In 1812, 532 vessels, with a tonnage of 116,687 tons, cleared at the port, 37 of which had been built at Quebec.

The war which commenced in 1812 between the United States and Britain severely checked the commerce of the St Lawrence, which was greatly dependent upon the Americans. And, notwithstanding that Britain slightly relieved the import duties on wheat in favour of Canada in 1814, we find that the trade of the colony from 1810 to 1820 remained almost stationary. The aggregate tonnage which arrived at Quebec in 1820 (a more prosperous year, if shipping be taken as the criterion, than any of the preceding ten), amounted only to 9697 tons over that of 1810. In 1810 26 vessels had been built in the colony, and only 7 were built in 1820.

According to the old system of colonial monopoly, the St Lawrence was rigidly closed against the entrance of foreign vessels, nor was any Canadian vessel allowed to enter a foreign port. The prosperity of the colony during this period of its infancy was believed not to have been materially checked by these restrictions, as the mother country at all times afforded an outlet for its surplus produce. After the United States had achieved their independence, their vessels were excluded from the ports of the British

[1] When not otherwise mentioned, all monies introduced in this article in connection with Canada are stated in provincial currency, which may be reduced to sterling by deducting a fifth. The sovereign is valued in Canada at 24s 4d., currency. The exact rule to reduce this currency into sterling is to multiply by 60 and divide by 73. To convert sterling into currency add 1-5th to the sterling, and 1-12th to the 1-5th.

colonies; and Canada, as a reward for its loyalty, received the exclusive privilege of supplying the West India islands with timber and provisions.

In this manner, as the trade of Canada had been confined and shackled for the supposed benefit of the mother country, so now was she to receive compensating privileges to the direct injury of the sister colonies of the West Indies. The United States ports were the natural resorts of the West Indies for timber and provisions, their distance from these being about one-half less than the ports of the St Lawrence. But the additional freight, which on such bulky articles constitutes a great proportion of the expense, was not only enhanced by this circuitous route, but the West Indies had to pay besides for transhipment upon such as were supplied by the United States to Canada for the West Indian market. The West India planters were thus laid under contribution for the support of the Canadian shippers and farmers.

These regulations were, however, so far relaxed in favour of the West Indies in 1822, that the wheat and lumber of the United States were allowed to be imported directly on payment of certain duties; but at the same time duties were imposed upon agricultural produce entering the British American colonies as well as the West Indies.

The immediate result of this measure, so far as it affected Canada, was that one-half of the export trade of the St Lawrence was at once destroyed. The simultaneous abundance of the English harvest, together with the restrictions then in force upon the importation of grain into Britain, even from her own colonies, forbade any exports thither, and thus seriously aggravated the depression of Canadian commerce, and afforded another illustration of the ruinous policy of bolstering up one class by privileges and exemptions, and shackling another by restrictions and duties.[1]

In 1825 Britain admitted Canadian flour and wheat into her ports at a fixed duty of 5s. sterling per quarter. Meanwhile a fresh trouble had already arisen to try the vexed fortunes of Canada. Previous to 1822, American exports to a considerable extent, as we have observed, sought the route of the St Lawrence, as if they had been of Canadian origin, very materially, of course, to the benefit of the trade of the colony. The opening of the Erie and Champlain canals in the United States, however, in 1825, drew off into a different channel those American exports which had formerly sought the Atlantic by way of Quebec, and the trade of the St Lawrence was thus seriously injured.

In 1826, however, we find the prospects again brightening. The Americans were allowed, after four years of exclusion, to export timber and ashes for the British market into Canada free of duty. The duty upon Canadian flour for the West India market was also reduced.

The trade of the colony likewise profited by the disputes between Britain and the United States, which led to the interdiction of the American export trade to the West Indies, which was reduced from L.500,000, in 1826, to less than L.500 in 1830.[2] While the results were such to the United States, we find the trade of the St Lawrence in 1830 not only fairly recovered from the effects of the imperial acts of 1822, but far surpassing its position at any former period. The arrivals at Quebec in 1830 were 967 vessels, having a tonnage of 238,153 tons.

In 1831 the trade of the colony was still further favoured by the action of the home government. The forest and agricultural products of the United States were admitted into Canada free of duty, and could be exported by the St Lawrence, as Canadian produce, to all countries except the United Kingdom. A differential duty was also at the same time imposed upon foreign timber entering the West Indian and South American possessions, greatly to the benefit of the colony, which also profited by the scarcity of food existing in Britain at this time. The arrivals at Quebec during this favoured and prosperous year, were 1016 vessels, with a tonnage of 261,218 tons, and the exports of flour and wheat by the St Lawrence were about 400,000 barrels, chiefly to Britain.

Between 1831 and 1836 we find a complete reversal of the order of trade between the colony and the mother country. The crops in England during that period being unusually abundant, and a scarcity of bread-stuffs existing in the United States, wheat was in 1833 shipped from Britain to Quebec. A supply also came from Archangel. These imports from Europe to the St Lawrence amounted in 1835 and 1836 to about 800,000 bushels.

The departure of the mother country from the protective policy in 1842 was viewed with alarm by the colonists, as fraught with disastrous consequences to their interests. Up to 1842 Baltic timber had paid an English import duty of 55s. per load, while Canadian timber entered England upon payment of 10s. per load. The duty on foreign timber was now reduced to 30s. and Canadian to 1s. per load; being a reduction of 25s. on Baltic and of only 9s. on Canadian timber. At the same time the free importation of United States flour into the colony was stopped, and the West Indies were allowed, on the payment of a duty of 2s. per barrel, to import their flour direct from the Americans.

These serious blows to the trade of the St Lawrence fell upon the colony at the period of a commercial crisis, and were therefore felt more severely. The number of vessels that entered the St Lawrence in 1842, from the sea, was 377 less than during the previous year.

In 1843, Canada was allowed to import American wheat under a comparatively nominal duty, and to export it through the St Lawrence as native produce to the British market. This measure, which may be viewed as having been the first indirect blow at the English corn-laws, amounted to a virtual premium of about 6s. sterling per quarter upon American exports to Britain through the St Lawrence.[3] The British ports were thus at once in a great measure thrown open to all the great wheat-growing countries of North America. Canadian exports were rapidly swelled in consequence; and in 1846 half a million of barrels, and as many bushels of wheat and flour, were shipped by the St Lawrence. The timber trade of the colony, which was also seriously threatened in 1842 by the large reduction of the duty on Baltic timber imported into England, witnessed likewise in 1845 and 1846, not merely a revival, but a very material increase. The number of vessels that entered the St Lawrence was 1699 during each of these years, having an aggregate burden of over 620,000 tons; this being far the largest amount of shipping that had ever in any previous years entered the St Lawrence.

This flush of prosperity to the trade of the colony was the result of the last in the series of those fitful changes which had characterized the commercial policy of the mother country in dealing with the colony.

In return, however, for the concessions which she made in favour of the timber and corn trade of the colony, England prevented the Canadians from employing any other than British vessels for exporting her produce from the St Lawrence. The result of such a restriction was, that a class of vessels making only two voyages in the year to Quebec or Montreal, and seeking no cargoes elsewhere, secured a monopoly at privileged rates, thus virtually imposing a tax both upon the exports and imports of the colony. Besides, Canada was not allowed to choose the best or cheapest market for the purchase of the tea, coffee, sugar, and manufactured articles she required. No foreign ship could enter the St Lawrence with a cargo, unless such ship were built

[1] *The Canals of Canada*, by T. C. Keefer, C.E., p. 24.

[2] Ibid. p. 24.

[3] Ibid. p. 27.

and owned in England, and sailed by a master and three-fourths of a crew the subjects of the country, proof of all which was exacted. Again, no foreign ship could take a cargo from the St Lawrence, except under these and other restrictions still more stringent.

The abolition of the British corn-laws, repealing all privileges in favour of Canadian bread-stuffs in the British market, seemed at first sight to be a heavy blow to the interests of the colony. Much of the trade of the St Lawrence appeared to be placed in jeopardy, and at the same time the trade of the colony with the United States was in a great measure interdicted by a hostile tariff. The changed and more enlightened views, however, which now entered into imperial legislation, materially assisted the growing energies and intelligence of the colonists. The imperial government formally abandoned in 1847 all control over the customs of the colony, which immediately set itself to the task of regulating its own trade. One of the first measures of the colonial legislature was to abolish in a great degree the differential and prohibitory duties on colonial imports along the United States frontier; and the Americans upon the other side of the St Lawrence were by this measure placed, as regards matters of trade, upon an equal footing with England. The beneficial effects of this measure showed itself at once in increased commercial activity and prosperity over the whole of Canada.

On the 1st January 1850, England crowned her free trade measures by relieving the colonies from the very injurious effects of the British navigation-laws.

The value of the more enlightened views which thus entered into both imperial and colonial legislation have since been most satisfactorily tested in the growing wealth and prosperity which have attended the progress of the colony; the trade of which has never been more flourishing, its financial position more satisfactory, its general interests more hopeful, than at the present moment.[1]

Exports.

The exports of Canadian produce and manufactures, shipped chiefly to Great Britain and the United States, amounted in 1853 to..L.5,945,757
The value of exports during 1852 was.............. 3,826,901

Showing an increase on the previous year of..........L.2,118,856

Comparing the exports of 1853 with those of 1848, we find that, during these six years, their value had more than doubled. Thus—

Exports, 1853..........................	L.5,945,757
Exports, 1848..........................	2,302,830
Showing an actual increase of.....	L.3,642,927[2]

The staple exports of Canada are timber, ashes, and bread-stuffs, besides other agricultural and forest products. The principal of these articles is timber. The amount of white pine exported in 1851 was 453,435 tons, valued at L.406,972; of this Britain received to the value of L.381,370, and the United States to the value of L.24,747. The supply of this single article of white pine has increased more than 50 per cent. during the last five years. Although the extinction of the duties which operated as a protection to Canadian timber in the British market has thus in a very marked manner been attended by an increased trade in white pine, yet the amount of red pine which leaves the country has greatly declined. In 1849, the export of red pine was 4,070,600 feet; it had fallen in 1853 to 2,315,160. The trade in pine deals has increased from 2,282,390 pieces in 1849, to 2,425,309 pieces in 1853.

The value of deals shipped in 1851 amounted to L.239,369, nearly the whole of which was for the British market. The quantity of planks and boards exported the same year amounted to 120,175,596 superficial feet, valued at L.209,138, nearly the whole of which was bought up for the United States market. The trade in Canadian forest products has increased in all from the value of L.1,600,000 in 1852, to an amount in 1853 of probably not less than L.2,250,000.

The duty upon Canadian square timber now entering Britain is 1s. per load, and upon sawn timber, such as battens, deals, and planks, the duty is 2s. per load. The great competition for freights, too, by the entrance of foreign vessels now into the St Lawrence, affords further facilities for the increase of the timber trade of Canada. With regard to the exports of sawn timber to the United States, Canada is enabled to carry on this trade in the face of a hostile tariff of 20 per cent. *ad valorem;* and notwithstanding this, the trade continues largely on the increase.

The United States government has not as yet acquiesced in the growing desire manifested in both countries to have the trade with Canada placed upon terms of reciprocity. Meanwhile it affords facilities to Canada for exporting and importing in bond through the United States territory, to the great benefit of its own shipping, as well as of its inland carrying trade by canal or railway, and consequently to the diversion of a large amount of the trade by the St Lawrence. These facilities of exporting and importing in bond are no doubt beneficial to the general interests of Canada. The exporter and producer are both benefited, to the extent of the greater saving either by lessened rates of inland transit or ocean freight. Were there no advantages to be gained, the mode of thus exporting or importing in bond through the United States would not be resorted to. The quantity of wheat and flour exported by Canada in bond to the United States from the shores of Lakes Erie and Ontario, by way of the river Hudson and New York, exceeded in 1850 the quantity exported by sea through the St Lawrence.[3]

Besides timber and bread-stuffs, Canada likewise largely exports pot and pearl ashes, classed under the head of products of the forest; this valuable staple of the colony being manufactured from the ashes of the burnt timber, collected chiefly in the process of clearing forest land preparatory to the labours of the husbandman. The value of ashes shipped from Canada in 1851 amounted to L.216,361, the greater part of which were destined for Great Britain. Horses appear in the exports from Canada to the United States in 1851 to the value of L.53,193. Furs and skins are also exported from Canada,—the largest amount being to the United States. Among other items of Canadian produce may be mentioned fresh, dried, and pickled fish; cows, oxen, sheep, butter, lard, pork, candles, wool, eggs, beans and pease, oats, hops, malt, flax and other seeds, iron, copper ore, and fine copper. Nearly the whole of these articles find a ready market in the United States. The chief exception is butter, of which exports to the value of L.36,402 in 1851 were shipped to Britain. The trade in copper and copper ore which has sprung up within the last few years, since the discovery of the mines along the shores of lakes Huron and Superior, promises soon to become very valuable and important.

Not the least important of Canadian exports now only remain to be mentioned. The trade in colonial-built ships is now one of considerable magnitude in British America, and is carried on under great facilities by the colonies. These facilities may be stated to be, the cheapness of materials on the spot where such are produced, the reasonable rates of wages at the ports during winter, and the advantage at all times secured of outward freight to Britain, where these ships find a

[1] A document of some weight bearing directly upon the subject, while illustrating and proving what has been here stated in the above brief historical review of the trade of Canada, has just reached England from the colony. This is the report of the council of the Quebec Board of Trade, dated April 3, 1854. "The year just passed," observe the Quebec merchants in this report, "has been one of great and general prosperity to the province, in which this city in every branch of export trade has fully shared. And the majority of this council, having been always strong advocates of free-trade principles, cannot but advert to the great advantages which have resulted to the Canadas since the establishment of such; and they refer with marked satisfaction to the yearly increasing numbers of foreign vessels frequenting the St Lawrence employed in carrying away our staple articles of export."

[2] Return from Inspector-General's Office, Customs Department, Quebec, March 24, 1854.

[3] Report to the United States Senate, by I. D. Andrews, United States Consul, &c. p. 412.

Canada.

market. During the ten years previous to 1852 the number of ships annually built at Quebec had varied from 37 to 70, with an aggregate burden of from 13,785 tons up to 41,505 tons. There are about 25 ship-building establishments at Quebec, and 8 or 10 floating docks, capable of receiving largest-class vessels. The class of vessels built range from 500 to 1500 tons and upwards; and a resident "Lloyd's surveyor" has recently been established at Quebec to inspect and class ships. The average cost is stated by Mr Israel D. Andrews to be from L.5, 10s. to L.7, 10s. currency per ton, and complete for sea for L.8 to L.10 currency per ton.[1]

The trade of Canada is chiefly carried on with Great Britain and the United States, the latter being now a rapidly growing market. Canada also exports to the sister North American colonies, to the West Indies, and to foreign countries.

Imports.

The imports of Canada, to which we have now to direct attention, comprise the very varied catalogue of necessaries and luxuries in demand by a highly prosperous people. According to official returns—

The imports of 1853 were	L.7,995,539
The imports of 1852,	5,071,623
Showing an increase on the previous year of	L.2,923,916[2]

Upon making a comparison with the returns for 1848, we find the value of Canadian imports of 1853 more than triple the amount of 1848, which only represented a value of L.2,429,584. The actual increase during these six years was L.5,365,955.

One item alone has materially assisted this rapid increase. Railroad iron is now being very largely introduced through the St Lawrence, a great part of which is for the gigantic railway undertakings now in progress. The larger proportion, however, imported in 1853 was for the consumption of the United States; the St Lawrence being the most economical route for heavy goods, and for emigrants destined for her western territories.

The value of railway bars imported through the St Lawrence in 1853, for use in Canada, was	L.205,846
Imported for use in the United States	220,333
Total value	L.435,179

representing not less than 39,810 tons railway bars, dead weight, imported in 90 British and 7 foreign vessels.

The appearance of foreign vessels in the St Lawrence is also a new and promising feature, and will prove of great benefit to Canada, as freights will thus be lessened by increased competition. Not fewer than 187 foreign vessels entered the port of Quebec during 1853; 53 of which were United States vessels, 88 Norwegian, 27 Prussian, 7 Portuguese, and 4 Swedish. The total number of arrivals at Quebec was—

	Vessels.	Tonnage.	Men.
1853	1351	570,738	19,360

The greater number of these vessels cleared for Great Britain, chiefly with cargoes of timber, others cleared for Nova Scotia, New Brunswick, Newfoundland, the United States, &c.

The class of manufactures most largely imported into Canada is cottons. In 1851 Canada purchased cottons to the value of L.976,366, of which L.741,292 were obtained from Britain, and L.234,689 from the United States. We here present a tabular view of some of the chief articles of import of 1851, distinguishing the proportions received from Great Britain and the United States.

	Great Britain.	United States.
Manufactures and Goods paying 12½ per cent. Duty.		
Cottons	L.741,292	L.234,689
Linen	102,436	11,198
Silk	156,901	35,602
Wool	591,337	136,143
Iron and hardware	316,902	144,746
Machinery	1,715	40,276
Paper	14,744	12,077
Leather, tanned	11,823	35,522
Oil	L.28,040	L.19,499
Glass	12,387	9,873
Fur	13,838	11,554
Articles not enumerated,	466,229	233,027
Goods paying 2½ per cent. Duty.		
Hides	L. 191	L.51,278
Iron-bar, rod, and sheet	119,144	1,642
Boiler plate, and railway bars	44,136	701
Pig-iron and scrap	45,444	1,282
Steel	18,095	762
Goods admitted Free.		
Books	L.13,230	L.55,027
Wheat	118	73,621
Settlers' goods	4,146	32,149
Unenumerated	3,591	6,183
Goods paying Specific and ad valorem *Duties.*		
Tea	L.21,196	L.237,490
Coffee	1,096	28,943
Sugar, refined	11,207	8,585
Do., other kinds	25,307	60,637
Tobacco, unmanufactured	239	14,933
Do., manufactured	449	94,479
Goods paying 30 per cent. Duty.		
Fruit, green	L. ...	L. 6,371
Do., dried	8,680	13,653
Spices	6,129	5,690

Trade with the United States.

Besides the value of these returns, in throwing some light upon the nature and extent of the demands of the colony for our manufactures and other goods, they afford some startling revelations of the extent to which our rivals of the United States supply the market. We find nearly one-fourth of the total demands of Canada for cotton manufactures are supplied from the manufactories of the United States.

The silks purchased by Canada from the United States are to a large extent the manufactures of France imported by the Americans, who also buy similar stuffs largely in the Indian market, besides bandanas and other handkerchiefs.

The description of goods classed as iron and hardware with which the United States supply the Canadian market, embrace large quantities of edge tools. These the Americans produce of a very excellent kind, and most ingeniously adapted to the required uses of the particular article.

It only now remains to mention another class of Canadian imports from the United States, and of which that country has almost a monopoly. Teas, coffees, sugars, fruits, wines, and spirits, are in a great measure purchased by the United States themselves, directly from the countries producing these commodities, and sold by the American merchants to Canadian retailers. The United States command the Canadian market for tea and coffee, for this reason, that American vessels, or foreign vessels entitled by reciprocal treaties to be exempt from discriminating duties, are allowed to introduce such articles into the United States direct from the place of growth duty free. The duty on tea supplied to Canada is 1d. per lb., with a further impostof 12½ per cent. Coffee pays from 4s. 8d. to 14s. per cwt., and a further *ad valorem* duty of 12½ per cent. Sugars pay from 9s. to 14s. per cwt. and an *ad valorem* duty of 12½ per cent. The above goods, such as teas, sugars, &c., classed as "paying specific and *ad valorem duties*," imported into Canada during 1851, are those which perhaps show the most considerable balance in favour of the United States as compared with Britain. The native manufactures of the United States, of almost every description, are, however, finding a rapidly increasing market in Canada. Those who have seen the reports of Messrs Whitworth and Wallis, the commissioners sent from England to the New York Industrial Exhibition, will be best able to form an opinion of the rivals British manufacturers have to meet in the people of the young republic.

Upper Canada, owing very much to its greater proximity to

[1] Report to the United States Senate, by I. D. Andrews, p. 421.

[2] Returns from Inspector-General's Office, Customs Department, Quebec, March 24, 1854.

Canada.

the United States, is already an important customer of America. The city of Hamilton, at the head of Lake Ontario, with a population in 1851 of 14,112, imported during that year from the United States goods to the value of upwards of *one million dollars*. The city of Toronto purchased from the United States in the same year to the amount of $1,525,620. The value of similar imports at the port of St John, foot of Lake Champlain, Lower Canada, amounted to $1,774,596. Other inland towns of Canada deal on an equally large scale with the United States. The subjoined official returns, from the valuable report to the United States Senate by Mr I. D. Andrews, present at one view the rapidly increasing trade of Canada, and the extent of that trade with the United States, which is almost wholly conducted through the inland ports.[1]

Value of Imports into Inland Ports of Canada from all Parts.

Ports.	1848.	1849.	1850.	1851.
Toronto.........	$788,900	$1,315,452	$2,538,888	$2,601,932
Hamilton	941,380	1,123,024	1,583,132	2,198,300
St John.........	1,106,692	1,213,640	1,477,784	1,948,460
Kingston	303,788	384,044	499,040	1,025,492

Value of Imports, 1851, *into Inland Ports of Canada from United States.*

Ports.	Total Imports, 1851, from all parts.	Amount from United States.
Toronto	$2,601,932	$1,525,620
Hamilton................	2,198,300	1,049,756
St John	1,948,460	1,774,596
Kingston	1,026,292	915,912

Mr Andrews gives the following statement of the total export and import trade between Canada and the United States in 1851.[2]

United States Imports from Canada, 1851.

Paying duty..............	$1,624,462	
In bond	1,593,324	
Free	94,464	
Total..........................		$3,312,250

United States Exports to Canada, 1851.

Domestic...................................... .	$5,495,873	
Foreign under bond, and Foreign not under bond, ...	3,440,363	
		$8,936,236

Showing a total amount of export and import trade between Canada and the United States of ... . } $12,248,486

The exports from Canada to the United States consist chiefly of sawn and roughly prepared timber, classed as lumber and shingles; and of bread-stuffs, chiefly flour and wheat. Cattle and horses, ashes, wool, butter, and eggs, are also in the list of exports. The returns of the Canadian customs and those of the United States customs for 1851 differ in amount to a considerable extent. It is probable, however, the different periods of the year at which the respective returns are made up explain this discrepancy.

The United States returns of imports from Canada in 1851 represent the value as .... } $3,312,250

The Canadian returns of exports to United States, 1851, represent the value as... ... . } $4,929,084

The amount of produce exported from Canada to the United States in bond for shipment at New York and Boston, amounted in 1851 to $1,546,534. This produce consisted chiefly of bread-stuffs, ashes, furs, and butter. The amount of Canadian wheat shipped at New York during the three years 1849, 1850, and 1851, was 1,478,704 bushels, valued at $1,040,914, of flour 633,722 barrels, valued at $2,337,124.

The great proportion of the lighter and more valuable articles of trade, such as dry goods and jewellery, which are introduced under bond into Canada through the United States, is received through Boston; and the heavier goods, such as railroad iron, chiefly through New York.

Canada.

Total imports into Canada in bond through United States, 1851, ...	$1,138,913

Trade of the great lakes.

The large and increasing amount of shipping on the great American lakes affords peculiar facilities for carrying on a prosperous trade between the countries on their northern and southern shores. These lakes, which are estimated to drain an area of 335,515 square miles, presented little more than 50 years ago, namely, in 1800, scarcely a craft above the size of an Indian canoe. The first American schooner on Lake Erie was built in 1797. The first steamer was launched on Lake Ontario in 1816. The American licensed tonnage of these two lakes, Erie and Ontario, amounted in 1851 to 176,852 tons, a large and increasing proportion of which was steam. The value of American commerce on the two lakes was estimated in 1851 at $239,712,520, which is nearly L.48,000,000 sterling. The precise American traffic of all the lakes was estimated by Mr Andrews in 1851 thus:—

	Tons.
Steam vessels.......	74,000
Sailing vessels	138,000
Total tonnage	212,000
Value of traffic...	$326,000,000

being upwards of L.65,000,000 sterling.

The total number of Canadian vessels, including those belonging to the ports of Quebec and Montreal, stood in 1849 thus:—

		Tons.
Steam vessels........................	103	14,149
Sailing vessels......	620	71,295
Total vessels and tonnage.........	723	85,444

The average capacity of the 157 American steam vessels on the lakes in 1851 was 437 tons; but the average of 25 of the largest fell little short of 1000 tons. The average of the 25 largest lake steamers in 1839 was not quite 500 tons.

With a summary in tabular form, we shall now close this important part of our subject, embracing the trade of Canada—

1. *Value of Canadian Imports*, 1851, *distinguishing Rates of Customs Duties, and Amount of Importations from respective Countries.*

	Great Britain.	United States.	British North America	West Indies.	Various foreign countries.	Total value.
	L.	L.	L.	L.	L.	L.
Goods paying specific and *ad valorem* duties	86,332	495,622	70,763	2902	87,640	743,261
30 per cent. duty..	15,263	26,460	974	299	5,153	48,151
20	1,879	12,450	3	—	81	14,414
12½	2,484,876	1,049,510	8,536	70	38,079	3,581,073
2½	350,372	161,389	1,287	6	6,070	519,126
Free..................	73,309	346,007	27,678	128	5,548	452,671
Grand total imp.	3,012,033	2,091,441	109,242	3406	142,574	5,358,607

2. *Value of Canadian Exports*, 1851, *showing Amounts exported to respective Countries.*

To Great Britain	L.1,505,351
To United States...........	1,017,836
To British North America	259,380
To West Indies.......	987
Other foreign countries	41,026
Total as above	L.2,824,630
Add ships built at Quebec.......	416,550
Add also 20 per cent. on exports from inland ports to make up for presumed deficiency in returns..	211,471
Total exports, 1851..............................	L.3,452,651

of which L.2,183,825 were by seaports, and L.1,268,826 by inland ports.

It will be observed from the above table, that notwithstanding the withdrawal of 31 Russian vessels which traded to the St Lawrence in 1852, the number of foreign vessels in 1853 has upon the whole largely increased.

The various movements that have taken place in connection with the trade between Canada and the United States, diverting a considerable portion of the trade of the colony from the St Lawrence, would prepare us for some marked effect in this direction, showing itself in the arrivals of vessels and tonnage at Quebec. Any such diversion of trade from this route of the St Lawrence seems not to have as yet caused any diminution, at least in the Quebec arrivals. And every vessel arriving there is believed to receive outward freight. The operation of the Canada Corn Act of 1843 gave a temporary impulse to the trade of Quebec and Montreal by the preference accorded in the British markets to produce conveyed by the St Lawrence. At present the facilities afforded by the United States government for the transportation of Canadian exports and imports in bond through its territory, and the multiplication of railways connecting the bank of the St Lawrence with different points on the coast, have contributed largely, however, to divert trade from the usual seaports of the colony.

Emigration.

It may be laid down as a fundamental principle, that colonies are as much governed by the laws of demand and supply in regard to the amounts of the various descriptions of population required, as are individuals, companies, or communities in their ordinary transactions; and any departure from those laws inflicts injury as much in the one case as in the other. Grand schemes of emigration, conducted, as at present, in the absence of precise and detailed information with regard to our colonies, would most probably present similar disheartening results which grand schemes of other shipments would which had not been "ordered," or had been sent without full acquaintance with the particular necessities or demands of the country. The history of every colony affords ample illustration of the truth of these remarks.

Canada.

The slight decrease upon previous years of the emigration of 1852 and 1853, both to the United States and to Canada, is owing, no doubt, to the improved condition of the working classes in Britain, and also in some measure to the larger flow of emigration to the Australian colonies. The emigration of 1853 to Canada is reported, by the chief agent for the superintendence of emigration stationed at Quebec, to have been of a satisfactory nature; the emigrants generally having afforded indications of the present improved condition of the home population. The present unsettled state of the continent of Europe will most probably direct a considerable flow of emigration to North America, and, as Canada is now becoming better known and appreciated, it will receive a share of these expected emigrants to swell its population.

The St Lawrence emigration embraces a large number destined for the western regions of the United States; while at the same time it is believed also a large number of the emigrants arriving at New York proceed to Canada. Of 7526 foreign emigrants referred to by Lord Elgin in his despatch of 22d December 1852, as having arrived in Canada in that year, 5159 were Germans and 2197 Norwegians. The whole of the Norwegians, Mr Buchanan, the chief emigrant agent, states in his report, proceeded direct to Milwaukie, on Lake Michigan. Of the Germans about 2000 are estimated to have remained in Canada.

The parliamentary papers relative to the emigration of 1853 present the following statement of arrivals at Quebec for the years 1852 and 1853, distinguishing the number of emigrants from the respective countries, thus:—

	1852.	1853.
From England, ...	9,585	9,276
„ Ireland, ...	14,417	15,983
„ Scotland,..............................	4,745	5,477
„ Germany,.............................	2,400	5,159
„ Norway,...............................	5,056	2,197
Lower ports of the Gulf of St Lawrence,	496	1,184
Total,..........................	36,699	39,276[1]

These "Lower Ports" which contributed to Canada in 1852 1184, and in 1853 496 emigrants were, it is believed, chiefly Scotch, or their descendants, from Cape Breton, Prince Edward's Island, and New Brunswick, who having disposed of their farms were removing to settle in Upper Canada.

The number of vessels engaged in the passenger trade to the St Lawrence in 1853 was 324, measuring 155,673 tons, and navigated by 5601 seamen. This shows a smaller number of vessels, but with a larger tonnage than during the previous year of 1852. Of this number, 47 were foreign vessels, 37 of which came from continental ports, and 10 from the United Kingdom. We here observe the gratifying fact of a further increase of foreign vessels to the St Lawrence during 1853, which shows the growing preference given to the St Lawrence for the conveyance of emigrants even for the western regions of the United States. Nearly the whole of the Norwegian emigrants of 1853 proceeded, as in 1852, direct to the Western States. A large number of the Germans of 1853, like those of 1852, settled in Upper Canada. Mr Buchanan estimates the number of emigrants who proceeded to the United States in 1853 at 11,504, the largest number of whom were Norwegians and Germans. Of the

[1] Papers relative to Emigration to the North American Colonies, presented to Parliament, April 1854.

Canada.

remaining 25,195, 19,000 are reported to have proceeded to Upper Canada; 1800 up the river Ottawa, the chief seat of the lumbering trade; and 4395 were absorbed into the populations of the Montreal and Quebec districts, and the eastern townships of Lower Canada, and employed on the railways and public works. In addition to the numbers who proceeded to Upper Canada by the St Lawrence, from 4500 to 5000 are believed to have entered the colony through the ports of Boston and New York, in addition to large numbers of labourers from the public works of the Western States, to be employed on the railways. The establishment of the Canada line of steamers had been already beneficially felt, by a large increase of cabin passengers from Liverpool during the season of 1853.

The numbers of persons who appear to have received assistance to emigrate in 1853, were, according to the report from the emigration department at Quebec, 122 from England, 1600 from Ireland, 351 from Scotland, and 31 from the Continent. The assistance was contributed by parishes, poor-law unions, and private individuals. Of the 351 persons who had received assistance to emigrate from Scotland, 332 were highlanders from the Glengary estate in Inverness-shire, who were provided with free passages by their landlord. They are reported by the emigration agent to have been a fine body of settlers. The remaining 19 persons were from Colonsay, Argyleshire. Of the 1600 persons assisted from Ireland, 1464 were sent out by poor-law unions, and received L.1665 sterling on landing at Quebec. It may be mentioned as somewhat remarkable in connection with this Irish emigration, that of the 1464 persons 1172 were females. This large proportion of females is accounted for by their having been sent out from the poor-law unions; coupled also, as Mr Buchanan observes, "with the pecuniary means afforded to females for joining their husbands, brothers, or male friends already established in the province." Mr Buchanan speaks very favourably of the orderly conduct and correct demeanour of those persons. They at once proceeded up the country; and the great majority who were in search of employment received such a few hours after landing at their destinations.

Many intelligent emigrants brought out with them a considerable amount of capital, and settled in Upper Canada. Importations of valuable stock had also taken place during 1853; a favourable indication, as Mr Buchanan remarks, of the wealth and progress of the country. Emigration is greatly assisted by the information and means transmitted by settlers in the colonies to their relations and friends in Britain. Very large sums are annually sent by settlers, to enable their friends to join them in the colony. The lowered rate of postage to Canada will tend much to increase the intercourse between the colony and parent country.

The following official return gives the number of emigrants who arrived at the ports of Quebec and New York respectively, during each of the five last years ending 1853

Years.	Quebec.	New York.
1849,	38,494	220,603

1850	32,961	223,078	16,037	8,773	280,849
1851	42,605	267,357	21,532	4,472	335,966
1852	32,873	244,261	87,881	3,749	368,764
1853	34,522	230,885	61,401	3,129	329,937

Revenue, Debt, and Public Works.

The revenue of Canada is chiefly derived from customs and excise duties, from public works, and the proceeds of public lands and forests, and an impost of one per cent. on the circulation of the notes of the chartered banks of the colony. The net revenue in 1853 amounted to L.1,193,497, thus:—

Customs,	L.986,597
Excise,	22,523
Public Works,	77,665
Territorial,	63,961
Bank Imposts,	23,053
Miscellaneous,	19,695
Total net revenue, 1853,	L.1,193,497[2]

Upon comparing these figures with former periods, we find the revenue to have almost quadrupled in twelve years. For 1854 it is estimated to exceed L.1,500,000. The expenditure of the country, for all purposes, is now about L.700,000; and for 1854 it will probably amount to L.750,000. The increase in the revenue since 1843 is shown in the following table:—

Years.	Revenue.
1843	L.320,987
1850	704,234
1851	842,184
1852	880,531
1853	1,193,497

Public debt.

The public debt of Canada is L.3,448,318. Of this amount, L.1,500,000 was raised with the guarantee of the British government. The amount recently authorized to be increased to aid in the construction of the Grand Trunk and Great Western railways, will increase the amount of the public debt to very nearly L.5,000,000 sterling. L 75,000 sterling is annually carried to a sinking fund for the extinction of the provincial debt, which amount is invested in consols in England for that purpose. Consols have lately been purchased by means of the surplus revenue, to provide for four years of the sinking fund in advance.[3]

Public works.

The public works of Canada have already attained some degree of celebrity both in America and England. "There is no country," observes Mr I. D. Andrews, in his report to the United States senate, "which possesses canals of the magnitude and importance of those in Canada." The Erie canal, which is the rival American water route for carrying the produce of the great western wheat-growing countries to the Atlantic sea-board, is capable only of transporting barges of 75 tons burden; whereas the canals of Canada are on a scale to allow of ocean-going vessels of from 350 to 500 tons, and carrying 4000 barrels of flour, to proceed through them, and thus accomplish an inland navigation into the heart of the continent for a distance of 1587 miles from tide water at Quebec.

The public productive works of Canada, consisting of canals, lighthouses, &c., yielded a net revenue in 1851 of L.58,738. The work yielding the largest amount of revenue was the Welland canal, extending from the head of Lake Ontario to the foot of Lake Erie, thus overcoming the interruption to navigation caused by the Falls of Niagara. The length of the main trunk of this canal is 28 miles, and of a feeder branch from the Grand river to the main trunk 21 miles. Its width at bottom is 35 feet, at top 71 feet, and the

[2] Statement, Inspector General's Office, Quebec, March 25, 1854.
[3] Official communication, Government House, Quebec, March 25, 1854.

Canada.

depth is 10 feet. The dimensions of the locks are from 150 to 200 feet in length, the width from 26½ to 45 feet, and the depth on meter 9½ feet. The amount of lockage is 346 feet, and the number of locks 27. This canal is also important as affording an unlimited supply of water-power to numbers of mills and factories on its banks. The St Lawrence canals, connecting Lake Ontario with the river St Lawrence at Montreal, extend in all to 40½ miles, having 27 locks, and an amount of lockage of 204¾ feet. The whole of these have the dimensions of their locks as large as those of the Welland canal, and have all 9 feet of water in these locks. The Lachine canal, cutting through the island of Montreal, is 8 miles in length and 10 feet deep. It is now in contemplation to construct another important canal, connecting Lake Champlain with the St Lawrence, and thus afford a more desirable route for the trade between the Hudson river and Canada and the western states.

Railways.

The gigantic railway enterprises now in progress in Canada are intended to embrace a railway system traversing nearly the entire length of the province from east to west, with branch feeders running into the main trunk line, and carrying off traffic to the leading American cities and Atlantic sea-board.

Besides the government aid to this complete railway system through Canada, these undertakings are understood to receive substantial support from United States interests, the great western country, as well as the north-eastern states of the Union, being directly interested in the success of these Canadian lines; more expeditious routes between the agricultural districts of the west and their centres of trade being opened up by them. One of the most valuable features of these railways to Canada will be their affording the province increased facilities of trade during winter, and uninterrupted communication with ocean traffic when inland navigation is closed.

The most important line of this comprehensive railway system is the Grand Trunk railway. The entire length of this line, when completed, will be 1112 miles. Its eastern terminus is at Trois Pistoles, in Lower Canada. Thence upwards it proceeds along the south shore of the St Lawrence, passing opposite to Quebec, and continuing thus westward, reaches Montreal. Before reaching Montreal, the line effects a junction at Richmond, in the Eastern Townships, with a line of railway to Portland, on the Atlantic, in the state of Maine. The part of the line between Montreal and Portland, a distance of 292 miles, is now open. The communication between Portland and Quebec will be opened in August 1854.

At Montreal, one of the most stupendous structures of modern times will carry the railway across the river St Lawrence, which is here two miles in width. This gigantic undertaking is now in course of construction, under the superintendence of Mr Robert Stephenson, whose name is associated with the well-known Britannia tubular bridge. The Victoria tubular bridge of Canada, will, however, far surpass Mr Stephenson's earlier work. The total span of the arches will be 6168 feet, besides piers on either side, running into the river, each about half a mile long. The span of the centre arch is 360 feet. The number of arches is 25, and, with the exception of the centre one, each has a span of 242 feet. The tube, which is of iron, is 25 feet high and 18 feet wide. The other parts of the work, including the half mile of piers on either side, are wholly of solid masonry. The height from the water level of the river to the floor of the iron tube, will be 60 feet. In order to impart some idea of the strength of this stupendous work, it may be mentioned that each buttress is calculated to resist the pressure of 70,000 tons of ice. The estimated cost of the Victoria tubular bridge is stated to be L.1,400,000.

From Montreal the Grand Trunk line follows the north bank of the St Lawrence, touching the towns of Cornwall, Prescott, and Brockville, to the city of Kingston on Lake Ontario. This distance from Montreal to Kingston is about 180 miles, about 120 of which, from Montreal to Prescott, will be opened in October 1855

A branch line of 55 miles, connected with this part of the main trunk, will be opened probably during 1854, from Bytown to Prescott, opposite to the American port of Ogdensburgh, where an important connection will be here formed with United States lines of railway. Another line of about 80 miles will also be constructed in connection with this section of the Grand Trunk from Montreal to Kingston. This is one from Bytown to Montreal, following the course of the Ottawa, and joining the Grand Trunk at Vaudreil, close to the Ottawa, and to the junction of that river with the St Lawrence.

The Grand Trunk line, proceeding westward from Kingston, skirts the shores of Lake Ontario, passing the Bay of Quinte, through the towns of Belleville, Cobourg, and Port Hope to Toronto, the capital of Upper Canada. The length of this section of the line, from Kingston to Toronto, is about 200 miles; the length of the line from Montreal to Toronto being 380 miles.

A branch of this section of the Grand Trunk from Kingston to Toronto, extending to 30 miles from Cobourg to the town of Peterborough, on the river Otanabee, will be opened in October 1855. Another line is also contemplated from Belleville to Peterborough. The most important line branching from this main section of the Grand Trunk, 45 miles of which are already open, is that from Toronto northward, passing Lake Simcoe, and thence continuing to the great Georgian Bay on Lake Huron. From Toronto the Grand Trunk railway proceeds directly westward through the fertile peninsula of Upper Canada, passing the towns of Guelph and Stratford, and terminating at the flourishing town of Sarnia, at the head of the River St Clair and south-eastern extremity of Lake Huron. The entire length of the Grand Trunk line which is now being pushed towards completion, namely that from St Thomas, 40 miles below Quebec, to Guelph in Upper Canada, will be opened in September 1856. The remaining portions of the system will not be so actively proceeded with. The direct distance from Trois Pistoles to Sarnia is 850 miles.

At Toronto another important railway system commences, known as the Great Western. This railway commences from a joint station at Toronto in connection with the Grand Trunk railway, and skirts the head of Lake Ontario to Hamilton, a distance of 45 miles. It thence proceeds westward through the heart of the settled parts of the great peninsula, situated between the lakes Ontario, Erie, and Huron, passing through Brantford, London, and Chatham, and terminates at Windsor, on the River Detroit, directly opposite to the American city of Detroit, in the state of Michigan. At this point an important connection takes place with United States railways.

The Great Western line, besides its terminus at Hamilton, diverges to the Falls of Niagara. The Great Western railway is now open from Windsor to Hamilton and Niagara Falls, a distance of 220 miles. That portion of it from Hamilton to Toronto, 45 miles in length, will be opened this year, 1854.

We have now (returning to Lower Canada) to mention the St Lawrence and Champlain railway, which connects the south bank of the St Lawrence, opposite to Montreal, with the head of Lake Champlain at Rouse's Point, a distance of 45 miles. At Rouse's Point this railway connects with the system of railways to Albany, Boston, New York, and other parts of the United States. The Plattsburg railway commences at Caughnawaga, on the south shore of the St Lawrence, opposite to Lachine, and runs to the town of Plattsburg on Lake Champlain, a distance of 28 miles. The Montreal and Lachine railway, a short line of 9 miles, connects the city of Montreal with the upper part of the island at the village of Lachine. This railway, as also a portion of the St Lawrence and Champlain line, have been in active operation for several years.

The average cost of the construction of railways in Canada will be about L.9500 per mile. The average fares are from 1d to 1½d. per mile, according to distance of journey. The electric telegraphs in Canada convey messages at much more moderate charges than in England.

Banks and Currency.

There are eight banks in Canada, besides the Bank of British North America, which has its chief office in England, and spreads its branches all over British America. This bank, which was incorporated in 1840, has a capital of L.1,000,000 sterling. Of the eight more strictly colonial banks, four are in Lower, and four in Upper Canada. The most important of these is the Bank of Montreal, incorporated with a capital of L.750,000 currency. The three other banks in Lower Canada are the City Bank of Montreal, with a capital of L.300,000; the Banque du Peuple in Montreal, with a capital of L.200,000; and the Quebec Bank. The banks in Upper Canada are the Bank of Upper Canada, Toronto, incorporated 1821, with a capital of L.500,000; the Commercial Bank of the Midland District, Kingston, incorporated 1832, with a capital of L.500,000; the Gore Bank, Hamilton, incorporated with a capital of L.100,000; and the Farmers' Joint Stock Banking Company, Toronto.

Almost all of these institutions have branches in various parts of the country, and issue notes, payable on demand, from one dollar upwards. The least denomination of the notes of the Bank of British North America is four-dollar notes, representing one pound colonial currency. The greater number of these institutions are now understood to be paying from 6 to 7 per cent. per annum upon their paid-up stock; and the stock of the most successful among them was selling, in April 1854, at from 16 to 25 per cent. premium. All accounts are kept in Canada in pounds, shillings, and pence, provincial currency. The present one pound of provincial currency is about equal to 16s. 4d. sterling. The English sovereign is equal to 24s. 4d. currency; the shilling within a fraction of 1s. 3d.; and the halfcrown about 3s. 1½d.

Post-office.

The control of the post-office of Canada was transferred from imperial to colonial authorities in 1851.

Previous to 1851, rates averaging 9d. currency, or about 7½d. sterling, the half-ounce, varying according to distance, were charged on all letters passing through the Canadian post-office. After that

date, a uniform rate of 3d., or about 2½d. sterling the half-ounce, for any distance within the province, was substituted for the old rates. The returns of the Canadian post-office department show that, in the year ending April 1852, 2,931,375 miles were travelled by the mail—being an increase of 444,360 miles over the previous year, when the post-office was under the control of imperial authority. As many as 243 new post-offices were also added to the establishment during this first year of colonial control. The gross revenue of the first year of reduced rates amounted to L.59,800.

General Government and Political Constitution.

The government of Canada is designed to resemble, as closely as possible, that of the mother country. A governor-general, appointed by the crown to represent sovereign interests—a ministry, termed the executive council, chosen by the governor, to act as his advisers, and to conduct chief public offices—two houses of legislature, one, the legislative council, nominated by the governor; the other, the legislative assembly, elected by the people.

Members of the house of assembly require to be possessed of freehold property of the value of L.800. Electors in counties, by a law which takes effect in 1855, require to be possessed of or to occupy property of the assessed actual value of L.50, or the yearly value of L.5. Electors in towns to be possessed of or to occupy property of the yearly value of L.7, 10s. Members of the house of assembly, during session, have an allowance for their services, and the body undergoes a new election every four years. The present number of members of the house of assembly is eighty-four. The act passed last session of the Canadian legislature increases the number of members of assembly after the present parliament, that is, in 1855, to 130. These are chiefly elected by counties, a small proportion being elected by incorporated towns and cities. The cities of Montreal and Quebec elect by the new act each three representatives, and Toronto two. Members of the legislative council are selected by the governor from among individuals of distinction and influence in the colony. The appointment is for life, and the individuals so appointed have the title of *Honourable.* The present number of members of the legislative council is forty. The members of the executive council or ministry require to possess seats in the house of assembly, and retain their offices so long as they have the confidence of this branch of the legislature.

The basis of the political constitution of Canada is the act of the imperial parliament, commonly known as the constitutional act, which was passed in 1791, during the ministry of Pitt In dividing the old province of Quebec (which then embraced the whole of Canada) into the two distinct governments of Upper and Lower Canada, this act of 1791 endeavoured to make full provision for establishing and carrying on a certain form of representative government for each of the new provinces. The practical working of the government of the colony has since then been further explained and modified, particularly since the re-union of the provinces by the imperial act of 1841. The result of this has been the introduction of a more harmonious action between the executive branch of the government and the representative assembly.

Bills passed by both houses have to receive the sovereign's assent previous to their becoming law, either at once, through the delegated authority of the governor, or within a limited period, when the sovereign's pleasure may be consulted on the particular measure.

Territorial Divisions and Municipal Government.

Lower Canada, chiefly for judicial purposes, is divided into five chief districts. These districts are subdivided by the new Parliamentary Representation Act into 58 counties, for legislative and municipal purposes. The counties are further subdivided into seigniories, townships, and parishes. The seigniories comprehend the original individual grants of land of the French government under the feudal system, and which were afterwards partitioned into parishes. The townships are divisions of counties made under the English government since 1796, in free and common socage.

Upper Canada was, until quite recently, divided into districts, and these were subdivided into counties and townships. The old territorial division of Upper Canada into districts has been abolished, and that of counties and unions of counties substituted, for judicial, municipal, and all other purposes. The size of a township is ten miles square, which territory again is subdivided into concessions and lots. A township is divided into eleven concessions or ranges, usually running east and west, with roads along the division lines; and each range or concession is further divided into twenty-eight lots, each lot containing two hundred acres.

Under the old division of Upper Canada into districts, the highest municipal bodies were the district councils. By the Colonial Act of 1849, abolishing the districts for judicial, municipal, and other purposes, the powers of these district municipalities were transferred to counties. Townships, cities, towns, and villages have also corporate powers for their respective local purposes.

The qualification necessary to be elected as a township councillor, is to be assessed on the roll for rateable real property, as proprietor or tenant, to the value of L.100. All resident householders are qualified to vote as electors. The number of councillors elected in each township is five. The elections are annual.

The county municipalities are composed of the presiding councillors of the townships, villages, and towns in each county. The duties of the county council are similar to those of the township council, with the exception that they embrace a higher range in regard to affairs connected with a more enlarged jurisdiction—such as the county roads and bridges, erection and maintenance of county hall, court-house, gaol, house of correction, house of industry, and also the support of grammar-schools.

Laws and Administration of Justice.

In Lower Canada the old French law, which was introduced into the country in 1663, during the reign of Louis XIV., is still, with some exceptions, the law of property. The laws enacted in France after that period extended only to the colony when enregistered there. At the time of the country being ceded to England, the laws, language, and customs of the French population in Lower Canada were guaranteed to them by treaty. The tenure of property in Lower Canada is therefore feudal, with the exception of that of lands in the townships. These lands have been laid out of late years in the district of St Francis, and partially in other districts, where new townships have been surveyed. These township lands are held in free and common socage. In order, in some measure, to remove the inconveniences of the feudal system in the seigniories, and to render titles to property more secure, a system of registration has recently been established. The commercial law of Lower Canada is understood to be regulated partly according to the English custom of merchants, and partly by the old French code. The criminal laws of England were introduced into Canada by 14th Geo. III., cap. 83. No English laws passed since that period became laws of Canada, unless particularly so specified, or unless made laws of the colony by acts of the colonial legislature. This state of the criminal law extends both to Upper and Lower Canada.

An act (12th Vict., cap 38) passed in 1849 by the legislature of Canada, abolished the old courts of queen's bench in the judicial districts of Lower Canada; and the offices of two judges of districts; and established for Lower Canada a court called the Superior Court, consisting of a chief justice and nine puisne judges; four of these puisne judges to reside at Quebec, four at Montreal, one at Three Rivers, and one at Sherbrooke. This court has original civil jurisdiction throughout Lower Canada, except in admiralty cases, and cases expressly confided to the circuit courts. Appeals are allowed to it from the inferior courts.

The circuit courts have original civil jurisdiction to the extent of L.50 currency, that is, about L.40 sterling. In cases not exceeding L.15 currency, or not relating to property titles, the proceedings are summary. Where the matter in dispute does not exceed L.6, 5s., the case is decided according to equity. In cases exceeding L.15, appeal is allowed to the superior court. The circuit courts have sittings each month at Quebec and Montreal, and at longer intervals in the lesser and more thinly-settled districts.

The court of appeals, which is also the court of queen's bench, by the late new act, has appellate civil jurisdiction, and also the jurisdiction of a court of error; and original jurisdiction in all criminal matters, except admiralty cases. This court consists of a chief justice and three puisne judges. The court of error and appeal has two terms yearly, in each of the cities of Quebec and Montreal. Appeals are allowed in certain cases to the Queen in privy-council. The criminal court holds two terms yearly in each district, with the exception of Gaspé. The admiralty court has its sittings in Quebec.

Commissioners' courts are held monthly in the country parishes, for the summary trial of small causes, affording an easy and expeditious mode of recovering petty debts not exceeding L.6, 5s. currency. The circuit judges are *ex officio* commissioners of these courts. These commissioners' courts only date from the passing of the Colonial Act, 7th Vict., cap. 19.

The advocates, barristers, attorneys, solicitors, and proctors-at-law, in Lower Canada, are incorporated under the name of the Bar of Lower Canada. Barristers may act as attorneys and solicitors at the same time in Canada. Pleadings may be written in French or English in Lower Canada, and both languages are spoken in the courts. Judges of the Superior Court are selected from barristers of ten years' standing, and judges of the circuit courts from barristers of five years' standing.

Such, at present, are the more prominent constituted arrangements for the administration of justice in Lower Canada. We have now only briefly to enumerate the arrangements for Upper Canada.

The new provincial act, passed in 1849, 12th Vict., cap. 63, established two superior courts of common law in Upper Canada.

Canada. These are the court of queen's bench and the court of common pleas; and it also provides for a court of error and appeal. The court of queen's bench and common pleas are each presided over by a chief justice and two puisne judges. The court of error and appeal is composed of the judges of the courts of queen's bench, common pleas, and chancery. The court of chancery is presided over by a chancellor and two vice-chancellors. All the fees of these courts are paid into the consolidated fund, out of which stated salaries are paid to the clerks and other officials. The courts all sit at Toronto. The circuits are held twice a-year in each county, except in the county of York, in which Toronto is situated, where there are three a-year.

The county courts of Upper Canada have original jurisdiction in civil matters to the extent of L.25 currency, in open account, and L.50 in cases of notes or bills, with trial by jury. Appeals are allowed to the courts of queen's bench or common pleas. The division courts are held in different places in each county, by the county judge, for the summary disposal of cases not exceeding L.10. A jury is allowed in certain cases, though seldom applied for. The probate court is in Toronto, and there are surrogates in each county. The heir and devisee court has its sittings in Toronto twice a-year, to determine claims to lands in Upper Canada, for which no crown patent has issued in favour of the proper claimants, being heirs, devisees, or assignees. The commissioners are the judges of the court of queen's bench, the vice-chancellor, and other persons specially appointed. Then there are the quarter-sessions, the chairman of which is the county judge, who, with one or more justices, holds a court four times a-year for trials of petty offences by jury.

Education.

The principal features of the system of education in Canada have been derived from those of the states of New York and Massachusetts, assisted by the text-books of the National Board of Education in Ireland, and the normal school system of training teachers. The system is carried out with the aid of a grant of L 41,095 annually, set apart by government, and divided between Upper and Lower Canada according to their respective populations. Every school municipality, however, before it can obtain its share of this fund, must raise an equal amount. In Upper Canada the sums greatly exceed the required minimum. The total amount available for educational purposes in Upper Canada in 1852 was L.176,074.

At the head of the whole system is a council of public instruction and a chief superintendent of schools for each division of the province, both appointed by the crown. The councils have the entire management of the provincial and model schools.

"The system of public instruction in Upper Canada," observes Dr Ryerson, the chief superintendent for that division of the province, "is ingrafted upon the municipal institutions of the country. The municipal council of each township divides such township into school sections of a suitable extent for one school in each, or for both a male and female school. The affairs of each school section are managed by three trustees, who hold their offices for three years, and one of whom is elected annually by the freeholders and householders of such section. The powers of trustees are ample to enable them to do all that the interests of a good school require—they are the legal representatives and guardians of their section in school matters. They determine whatever sum or sums are necessary for the furnishing, &c., of their school and the salaries of teachers, but account for its expenditure annually to their constituents, and report fully to the local superintendent by filling up blank forms of annual reports which are furnished to them by the chief superintendent of schools from year to year. The township council imposes assessments for the erection of school-houses, or for any other school purpose desired by the inhabitants of school sections through their trustees. The inhabitants of each school section decide as to the *manner* in which they will support their school according to the estimates and engagements made by the trustees, whether by voluntary subscription, by rate-bills on parents sending children to the schools, or by rates on the property of all according to its assessed value, and opening the school to the children of all without exception. The latter mode is likely to supersede both the others; but its existence and operation, in connection with each school, depend upon the annual decision of the inhabitants of each school section at a public meeting called for that purpose.

The law also provides a system adapted to the circumstances of cities, towns, and incorporated villages. In each city and town there is one board of trustees for the management of all the schools in such city or town—two trustees elected for each ward, and holding office for two years—one retiring annually. In each incorporated village not divided into wards, there is a board of six trustees elected—two retiring from office and two elected, each year. These boards of trustees, thus constituted, appoint the local superintendent, and determine upon the number and kinds of schools, the employment of teachers, and all the expenses necessary for the schools in each such city, town, or incorporated village; and the municipal council is required in each case to raise the sum or sums estimated by the board of trustees for all their school purposes, and in the manner that they shall desire. There is also the same provision for the establishment of libraries in each city, town, and village, as exists in respect to their establishment in each township and county."[1] Canada.

The principle of recognising and combining in their official character all the clergy of the country, with their people, in the practical operation of the school system of Upper Canada, Dr Ryerson states, has been found to be eminently successful. Absolute parental supremacy is maintained by the people in the religious instruction of their children, providing for it according to circumstances, and under the auspices of the elected trustee-representatives of each school municipality. And with regard to the clergy, the same authority observes, that while they have free access to each school, "no instance has been known in which the school has been made the place of religious discord, but many instances, especially on occasions of quarterly public examinations, in which the school has witnessed the assemblage and friendly intercourse of various religious persuasions, and thus become the radiating centre of a spirit of Christian charity and potent co-operation in the primary work of a people's civilization and happiness."[2]

The returns for 1852 showed that in Upper Canada there were in that year 3010 common schools in operation, attended by 179,587 pupils, and that the total sum available for teachers' salaries, and for the erection and repair of school-houses, was L.139,285, this sum exceeding by three-fourths most probably the amount of the parliamentary grant. "In Lower Canada," observes the Earl of Elgin in his despatch of December 22, 1852, "where direct taxation is especially distasteful, the levy of a local rate was made compulsory, and attended for a time with some difficulty. The people in this part of the province are, however, becoming generally reconciled to a tax from which they derive so palpable a benefit, and the common school system is making satisfactory progress among them likewise."

Table showing the State and Progress of Education in Upper Canada, from 1849 to 1852 inclusive.[3]

Subjects Compared.	1849.	1850.	1851.	1852.
Population of Upper Canada	...	809,493	950,551	953,239

[1] Proceedings at the ceremony of laying the foundation stone of the Normal and Model Schools and Education Offices for Upper Canada, July 2, 1851. With sketch of the system of Public Instruction. By the Chief Superintendent of Schools. Toronto 1851, pp. 7, 8.

[2] Ibid. p. 7.

[3] Appended to *Canada, its Present Condition, &c.,* by William Hutton, Secretary to the Government Board of Statistics in Canada. London, 1854.

The Normal and Model School for Upper Canada, the support of which is provided for by appropriating a small portion of the common school fund, was established by the legislature in 1846, and has been very successful. The commodious building for this school and for education offices, the foundation stone of which was laid in 1851, is designed to accommodate 200 teachers in training, and 600 pupils to the model school. Rooms are also set apart for a school of art and design, in which it is proposed, by the aid of a legislative grant, to give a special course of instruction adapted to the interests and progress of the mechanical arts and manufactures.

There are no fewer than five universities in Canada, four in Upper Canada, and one in Lower Canada. There are also seven colleges, six of these in the upper, and one in the lower province. The universities are, the University of Toronto—Trinity College, Toronto—Queen's College, Kingston—Victoria College, Cobourg—and M'Gill College, Montreal. The colleges are, University College, Upper Canada College, Knox's College, St Michael College, Toronto, College of Regiopolis, Kingston, College of Bytown, and Bishop's College, Lennoxtown, Lower Canada. The charge for board and tuition at several of these higher educational institutions, where the system of education is similar to that of the English universities, is understood to vary from L.30 to L.50 per annum.

Religion.

The prevailing creed in Lower Canada is that of the Church of Rome, and in Upper Canada the largest denomination is that of the Church of England. The following tables from the census for 1851, present a classification of the chief religious bodies of Upper and Lower Canada.

1. *Upper Canada.*

Church of England,		223,190
Church of Scotland,	57,542	
Free Presbyterian Church,	65,807	
Other Presbyterians,	89,799	
		213,148
Wesleyan Methodists,	96,640	
Episcopal Methodists,	43,884	
Other Methodists,	67,132	
		207,656
Church of Rome,		167,695
Baptists,		45,353
Lutherans,		12,089
Congregationalists,		7,747
Quakers,		7,460
Other denominations and creeds not classed,		67,766
Total population,		952,004

2. *Lower Canada.*

Church of Rome,		746,866
Church of England,		45,402
Church of Scotland,	4,047	
Free Presbyterian Church,	267	
Other Presbyterians,	29,221	
		33,535
Wesleyan Methodists,	5,799	
Other Methodists,	3,449	
		9,248
Baptists,		4,493
Congregationalists,		3,927
Other denominations and creeds not classed,		46,790
Total population,		890,261

The Church of England, presided over by the bishops of Quebec, Montreal, and Toronto, had in 1851 these three dioceses, and 242 clergymen. The Church of Rome had seven dioceses and 543 clergymen. The Presbyterian Church of Canada, in connection with the Church of Scotland, had in 1853, 70 ministers, and about 40 vacant charges. The Presbyterian Church of Canada, in connection with the Free Church of Scotland, had in 1853, 90 ministers, and also about 40 vacant charges. The United Presbyterian Synod in Canada had 50 ministers, and about 15 vacant charges. The Wesleyan Methodists had 216 ministers and 9 vacant charges. Other Methodists had 175 ministers, and a number of vacant charges. The Congregational denomination had 48 ministers and 10 vacant charges. The Baptist denomination had 136 ministers and 16 vacant charges. The clergy of all denominations in Canada amounted in 1851 to 1500, of which number 641 were in Lower, and 859 in Upper Canada.

In Lower Canada the Roman Catholic religion is secured in the immunities and privileges it possessed under the French government. The lands which then belonged to that church, and the twenty-sixth part of the grain raised on farms cultivated by Catholics, are secured to it by law. One-seventh part of all the lands in the townships of Lower Canada, as well as of Upper Canada, were secured by an act of the imperial parliament, which has been called the Constitutional Act of 1791, for the support of the Protestant clergy. This government appropriation of lands, known as the Clergy Reserves, has given rise to lengthened and embittered party discussions, both in the imperial and colonial legislatures. The imperial legislature have recently, however, by act 16th Vict., cap. 24, passed May 9, 1853, given over the question, to be settled by the colonists themselves. The colonial legislature has not yet dealt with the question, and at present the proceeds of these lands are distributed to the leading religious denominations in the colony, the Church of Rome in Lower Canada excepted. The following is a statement of the

Appropriation of the Clergy Reserve Funds in 1851.

1. *Upper Canada.*

History.

If we except the ancient Scandinavian voyages, the discovery of the American continent may be ascribed to John and Sebastian Cabot, who, under the auspices of Henry VII., visited the coast of Labrador in June 1497, nearly four months before Columbus came in sight of the mainland.[1] To Gaspar Cortereal, the next voyager in the course of the Cabots, is said to be due the discovery of the Gulf of St Lawrence. Other parts of the country were from time to time discovered by various expeditions, French and English; but not until 1535 were these attended by any material results of extended knowledge of the country. In that year Jacques Cartier, under the auspices of Francis I. of France, entering the St Lawrence, ascended the river to the spot where Montreal now stands, where there was then a circular Indian village surrounded by palisades, and situated amidst cultivated fields of Indian corn. In the year 1608 these and other discoveries were first turned to some practical account, when Champlain laid the foundation of the city of Quebec, and a French colony was established in the country. The settlement, however, continued to maintain a precarious existence; its administration being committed chiefly to trading companies, whose object was immediate gain, or to military governors who involved the colonists in perpetual feuds. For a century and a half the history of French colonization in the New World, occasionally relieved by the efforts and achievements of able and good men, is little else than a mere chronicle of bloody and harassing warfare with the native Indians, and latterly with the rival settlements of Great Britain. Some slight improvement, indeed, took place in the prospects of the colony in 1663, when Louis XIV., under the direction of his minister Colbert, erected Canada into a royal government with the laws and usages of France.

The treaty of Utrecht in 1713 gave a short peace to Canada, and enabled the governor, Marquis de Vaudreuil, to direct his attention to the improvement of the province, the trade and agriculture of which continued to prosper under his wise and vigilant administration. War again breaking out between Great Britain and France, the co-

[1] *History of the Travayles in the East and West Indies.* By R. Eden and R. Wills, 1577, fol. 267. Bancroft's *History of the United States*, vol. i., p. 11.

Canada. lonies were involved in hostilities. It had been the policy of France to hem in the English settlements in North America by a chain of forts extending from the Gulf of St Lawrence to the Gulf of Mexico. The jealousy of the English being kindled by this and other circumstances, it was resolved, in the course of the war, which was begun in 1755, to send an overwhelming force to North America, for the purpose of expelling the French from that quarter of the world. The army under General Amherst having, however, made indifferent progress, an expedition against Quebec was despatched from England in 1759, the chief command of which was confided to Major-General Wolfe, who, landing above Quebec on the 13th September 1759, carried the heights of Abraham, and defeated the French under the Marquis of Montcalm, who, along with Wolfe himself, was killed in the action. Quebec submitted in a few days, and soon afterwards Montreal and the whole country, which was finally ceded to Great Britain by the peace of 1763. So much had the country suffered during the French sway, chiefly through the combined ravages of war and want, that in 1759 the population had only reached 65,000. The Catholic religion was confirmed in all its rights and privileges to the French settlers; and the French laws were retained. The original inhabitants, thus conciliated, became the faithful subjects of the new sovereign; and when all the other American colonies rebelled against the tyranny of the mother country, they submitted to the imposition of the stamp act, and even took up arms to defend the country against an inroad of the American forces in 1775 under Generals Montgomery and Arnold. In 1791 the colony received a constitution, and was divided into Upper and Lower Canada; and the first parliament was held in Upper Canada in 1796. While the country was advancing in a career of prosperity, the war of 1812 broke out between the United States and Great Britain, and the frontier of Canada again became the scene of military operations. In the summer of that year the American forces under General Hull entered Upper Canada, and were completely defeated, and the greater part made prisoners by General Sir Isaac Brock. Another body of American troops collecting on the Niagara frontier, passed over into Canada in November, and were routed with severe loss on the heights of Queenstown by General Brock, who was unfortunately slain in the action. The Americans renewed their attempts on the Niagara frontier with no better success than before. Early in 1813, however, they succeeded in taking possession of York and Niagara, and shortly afterwards the British were foiled in an attack on Sackett's harbour. In January 1813, the American general, Winchester, was made prisoner, with the whole of his troops. To counterbalance this success, the American commodore captured all the British vessels on Lake Erie; and General Proctor was defeated near Detroit. The British were consequently obliged to retire, and an American army advanced in three divisions towards Montreal. One of these divisions, amounting to 7000 troops, was defeated by the Canadian militia; and another division meeting no better fortune, the whole American army retreated within their own territory, and thus terminated the campaign of 1813. The campaign of 1814 was decidedly favourable to the Americans. They were repelled at first in attempting to invade Canada. But the capture of Fort Erie by General Brown was an important success; whilst Sir George Prevost, who attacked Plattsburg with a force of 11,000 men, was repulsed with great loss; and the British squadron fitted out on Lake Champlain was defeated by the American force under Commodore Macdonough. The British were making great exertions to recover their ascendancy both by sea and land, when the treaty of Ghent, signed in December 1814, happily terminated the war, in which the loyalty of the Canadians both of British and French extraction was nobly vindicated.

Canada The subsequent history of Canada has been chequered by a course of dissensions between the provincial houses of assembly in Upper and Lower Canada and the respective executive governments, in which the home government also shared. The working of the system of provincial government, especially in the executive departments, had ceased to harmonize with public feeling, and acted in opposition to the expressed wishes of the popular branch of the legislature. Various abuses had crept into the administration, which were fostered by the high functionaries who held irresponsible offices, who guided the counsels of the successive governors more to their own advantage than to the interests of the province. The control and appropriation of the revenues and public offices were urgently demanded in Lower Canada, and were in part conceded; but many of the grievances remaining unredressed, disaffected leaders made use of them to goad the people to the brink of insurrection in 1836; the concessions of Lord Gosford and the home authorities being deemed insufficient. The disaffected of Lower Canada were joined by the malcontents of the upper province, and in the following year the whole of Canada broke out into open rebellion. On the 6th November 1837, the city of Montreal was disturbed by a body of 250 members of a secret association called *Les Fils de la liberté*. In various other parts of the country serious outrages were perpetrated. In the neighbourhood of Toronto, a large body of insurgents, who were organizing an attack upon the town, were routed and dispersed by a force of militia under Sir Francis Head. Their leader, after many adventures, escaped into the United States in female attire. The influence of the disaffected had in the meantime extended itself across the American frontier, and troops of "sympathizers" passed into Canada with the view of assisting the rebels. This outbreak, which continued throughout 1837 and 1838, elicited in a very decisive manner the loyalty of the great majority of the colonists; and as they were now in possession of the means to repel any assault, the numbers of the insurgents gradually melted away, and tranquillity was again restored. It was some time, however, before the rancour of party feeling was allayed, and the colony once more assumed an aspect of progress and prosperity.

The appointment of the Earl of Durham as governor-general and high commissioner in 1838, for the adjustment of the affairs of the colony—followed by that of Mr Poulett Thompson, afterwards Lord Sydenham, in 1839—the success and remarkable vigour of his government—and the prudent administrations of subsequent governors, aided by discreet and able counsels of colonial ministers in the home government, together with the late recognition of colonial control of internal affairs—have completely gained the confidence of the colonists, and insured the uninterrupted welfare of Canada. (J. B. B.)

CANAL. See Navigation, Inland.

Canal, in *Anatomy*, a duct or passage through which any of the juices flow.

Canal de Principe, a channel on the N.W. coast of North America, formed by Banks' Island on the S.W., and Pitt's Archipelago on the N.E. It was first explored by Señhor Camaano, a Spaniard, who represented it as fair and navigable. It is about fourteen leagues long. The southern shore is compact and nearly straight, and has no soundings. The northern shore is much broken, bounded by many rocks and islets, and affords soundings in several places. Both sides of this canal are entirely covered with pine trees; and the shores abound with sea-otters.

CANALE, or Canaletto, Antonio, a Venetian painter, was bred with his father, a scene-painter at Venice. In 1719 he went to Rome, where he employed himself chiefly in delineating ancient ruins, and studied the effect of light and shade, in which he became an adept. On returning home he devoted his powers to views in his native city, which he painted with a clear and firm touch, introducing groups of figures with much effect. In his later days he resided some time in England. His pictures are greatly esteemed. According to Zanetti, he died in 1768, aged seventy-one.

CANANDAIGUA, the capital of the county of Ontario, in the state of New York, situated on the western side of the lake of the same name, 177 miles west of Albany. It is pleasantly situated, and has numerous elegant buildings. Pop. 6212. The lake is about 14 miles in length, with an average breadth of one mile, and by means of the river of the same name its waters are conveyed to the Seneca river.

CANANORE, a town and small district of Hindustan, on the sea-coast of the province of Malabar. The town is situated at the bottom of a small bay, which is one of the best on the coast. It is defended by a fortress situated on the point that forms the bay, and which, since the province has been ceded to the East India Company, has been strengthened with works after the European fashion, now forming the headquarters of the province. The town contains several good houses that belong to Mohammedan merchants; and although the exports have been diminished by the prevailing disturbances of the country, it still carries on a flourishing trade. The people have no communication with the Maldives, although the sultan and the inhabitants of these islands are Mohammedans.

The small district around Cananore extends nowhere more than two miles from the glacis of the fort. It consists of low hills, very bare, but not of a bad soil, interspersed with narrow valleys; and the whole is cultivated once in three, six, or nine years, according to the quality of the soil. A very small proportion of it consists of low rice ground, which is well drained, and carefully irrigated.

The proper name of Cananore is Canura. The Portuguese landed here in 1501, and were the first Europeans who visited this coast. They built a fort, the walls of which have been recently improved. The Portuguese were expelled by the Dutch in 1664, who sold it to a native family, now represented by a female sovereign, a Mohammedan, who is also sovereign of the Laccadive Islands, and who pays an annual tribute of 14,000 rupees to the East India Company. The family were, prior to this, of very little consequence, and entirely dependent on the Cherical rajahs; but having acquired a fortress which was considered as impregnable, they became powerful and were looked up to as the head of all the Mussulmans of Malayala. This princess has but a very small territory, and would be unable to support herself without the assistance of trade. She possesses, accordingly, several vessels that sail to Arabia, Bengal, Sumatra, and Surat, whence horses, almonds, piece goods, sugar, opium, silk, benzoin, and camphor, are imported. The exports principally consist of pepper and cardamoms, sandal-wood, coir, and sharks' fins. A proposal has been recently made to the Beebee or princess for the transfer to the British government of the Laccadive Islands, in consideration of a pecuniary equivalent. Cananore is fifteen miles N.E. of Tellicherry, and 100 W.S.W. of Seringapatam. E. Long. 75. 25., N. Lat. 11. 51.

CANARA, a province of Hindustan, extending between the twelfth and sixteenth degrees of north latitude. It is a narrow strip of territory running along the western coast of India, 200 miles in length by thirty-five in breadth; and is hemmed in on the east by the great ridge of the Ghaut Mountains. It is bounded on the north by the Portuguese territory of Goa, on the south by Malabar, on the east by Mysore and the Balaghaut territories, and on the west by the Indian Ocean.

Canara is a corruption of Karnata, the table-land above the Ghaut Mountains. It is a rocky and uneven country, where cattle are scarce, and where, even when they can be procured, they cannot always be employed; where every spot, before it can be cultivated, must be levelled by the hand of man; and where even the land that has been brought under cultivation, if it be neglected for a few years, is soon broken into deep gullies by the heavy torrents of rain which fall during the monsoons. The land is divided into small properties, and the country flourishes from the minute attention bestowed by each proprietor on his own little spot. It is not likely that Canara will ever become a manufacturing country, as it does not produce the necessary materials, and also on account of the heavy rains, which oppose insurmountable obstacles to all operations which require to be carried on under a clear sky. But these same rains give it a never-failing succession of rice crops, which are exported to Malabar, Goa, Bombay, and Arabia. "Canara," says Sir Thomas Munro,[1] "produces nothing but rice and cocoa nuts; its dry lands are totally unproductive, so that the little wheat or other dry grain that is raised is sown in the paddy fields, where the water has been insufficient for the rice. It produces hardly any pepper. The sandal-wood for exportation comes all from Nuggar and Soonda. The soil is perhaps the poorest in India. The eternal rains have long washed away the rich parts, if ever it had any, and left nothing but sand and gravel." In another letter he observes, "there is hardly a spot in Canara where one can walk with any satisfaction, for the country is the most broken and rugged perhaps in the world. The few narrow plains that are in it are under water at one season of the year; and during the dry weather the numberless banks which divide them make it very disagreeable and fatiguing to walk over them. There is hardly such a thing as a piece of gently rising ground in the whole country. All the high grounds start up at once in the shape of so many inverted tea-cups, and they are rocky, covered with wood, and difficult of ascent, and so crowded together that they leave very little room for valleys between." It was in ancient times in a very flourishing state, while it remained under its Hindu sovereigns, principally owing to the moderate land-tax to which it was subjected. An increase was made of fifty per cent. to this tax under the Bednore family, besides many smaller additions, making twenty per cent. more. But all these taxes were easily paid by the inhabitants; and the country, if it did not advance in population and wealth, fully maintained the position to which it had attained. Canara was conquered by Hyder in 1762; and at that time it was a highly improved country, filled with industrious inhabitants, who enjoyed a greater degree of prosperity, and were more moderately taxed, than the subjects of any native

[1] See *Life of Sir Thomas Munro*, chap. iv. Letter dated Huldipore, 20th December 1799.

Canara.

power in India. But no sooner was its conquest completed than Hyder ordered an investigation into every source of revenue, for the purpose of augmenting it wherever it could be done. These exactions were augmented by his son Tippoo, who was determined to relinquish no part of his father's revenue, and whose policy it was to hold one part of the proprietors and husbandmen liable for the deficiencies of their neighbours. The effect of these violent regulations was to hasten the extinction of all the ancient proprietors of the soil, and to deteriorate the value of the lands until they became unsaleable. In this manner the agriculture of the country was heavily oppressed; and Canara, when it came into the possession of the British, had completely fallen from its ancient prosperity. It is said, in the report of the principal collector of Canara,[1] "the evils which have been accumulating in the country since it became a province of Mysore have destroyed a great part of its former population, and rendered its inhabitants as poor as those of the neighbouring countries." The value of landed property has been greatly reduced; and those lands which are worth anything are reduced to a very small portion, and lie chiefly between the Cundapoor and Chundergherry rivers, and within five miles of the sea. But it is only here and there even in this tract that lands are to be found which can be sold at any price. There is scarcely any saleable land even on the sea-coast to the northward of Cundapoor, or anywhere except on the banks of the Mangalore and some of the other great rivers. The inland tracts near the Ghaut Mountains are generally waste and overgrown with wood. By the oppressions of its conquerors the population of the country has been diminished about one-third; and the value of property has been reduced in an equal proportion. "It may be said," observes the principal collector, in his report, "that this change in the condition of the country was brought about by the invasion of Hyder; by the four wars which have happened since that event; by Tippoo himself destroying many of the principal towns on the coast, and forcing their inhabitants to remove to Jumalabad and other unhealthy stations near the hills; by his seizing in one night all the Christian men, women, and children, amounting to above 60,000, and sending them into captivity to Mysore; by the prohibition of foreign trade; and by the general corruption of his government in all its departments." These circumstances, according to the opinion of the collector, accelerated the change; "but they probably," he adds, "did not contribute to it so much as the extraordinary augmentation of the land rents." "Whole villages," says Colonel Munro, who after the conquest of the country was appointed by the Company to survey it, and to reclaim it from its wild and unsettled state, "have in some places been abandoned by the owners, from the exorbitance of the assessment; in others they are barely able to keep their ground and to subsist; in others the rent is so moderate that the lands are saleable."[2]

On the fall of Tippoo in 1799, Canara passed to the East India Company. The territory was in the first instance placed under the management of Colonel Munro, by whose vigilance and activity order was gradually restored. The people rejoiced in the protection they received; and under the equal rule of the British government the country soon began to revive from the state in which it had languished under its former tyrants. The assessment of this district has long been a subject of discussion among the local authorities, and much difference of opinion has been manifested in regard to the best mode to be adopted for placing it on a satisfactory footing. The government demand, though upon the whole moderate, is stated to be unequally distributed; but notwithstanding this inequality, the country has greatly increased in wealth and population, and a marked improvement is reported to have taken place in the condition of the people, which is exhibited in the dress, in the mode of living, and in the increase of their personal comforts. The lands are held for the most part under the Ryotwar tenure; and a maximum rent fixed for the best lands, which cannot be exceeded. Inferior lands, so long as they remain inferior, are of course assessed at lower rates, and the contracts with the cultivators are renewed from year to year, when remissions of rent are made if the unfavourable character of the season or the circumstances of the cultivator render such a measure expedient. Doubtless the greatest blessing which the British government could confer on the country would be the abandonment of the annual settlement, and the introduction of the revenue system which prevails in the north-western provinces of Bengal, where the government demand is limited to a fixed proportion of the net rent, and leases are granted for periods of thirty years. By this limitation of the public demand, a valuable and marketable private property is created in the land, and every cultivator, however petty his holding, becomes to a certain extent a capitalist. But before such an arrangement can be carried out, a new survey of the district must be made, and such a measure is in contemplation. In the mean time a regulation has been promulgated, under which the full benefit of all agricultural improvements effected by the cultivators has been secured to them, and no additional assessment is to be imposed on that account so long as the general rates of the district remain unaltered. The district consists of two divisions, North Canara and South Canara; and their aggregate population is officially returned at 1,056,333.

Canara, North. This division of Canara is situated between the thirteenth and the sixteenth degrees of northern latitude, and contains three smaller districts—Cundapoor, Onore, and Ancola. Its sea-coast, which is 100 miles in length, has scarcely any sinuosities, and within its whole extent there is hardly a safe station for large vessels. Here the Western Ghauts, although steep and stony, are by no means rugged or broken with rocks. On the contrary, the stones are buried in a rich mould; and the sides of the mountains are clothed with the most stately forests, in which are seen the finest bamboos and the most stately palms. There is no underwood or creeper to interrupt the passage through these woods; but they are infested with numerous tigers, and the climate is very unhealthy. The district of Ancola is larger than the other two, though, having suffered more severely from the ravages of Mahratta warfare, it does not yield above half the revenue of the other two. North Canara produces sandal-wood, sugar-canes, teak, wild cinnamon, nutmegs, and pepper. About midway up the Ghauts the teak becomes very common. In many parts, as in the western districts of Soonda, the cultivation of gardens is the chief object of the farmer. In these gardens are raised promiscuously betel-nut and betel-leaf, black pepper, cardamoms, and plantains. Towards the eastern side of the province there are very few gardens, but along the courses of the streams, and those of the plain country in general where water may be obtained by digging to the depth of a few feet, the lands are well suited for cultivation. Here the great object of cultivation is rice; and although the rains are not so heavy as to the westward, yet in cooler seasons, on a moist soil, they are sufficient to bring to maturity a crop of rice that requires six months to ripen. A few of the highest fields are cultivated with a kind of rice that ripens in three months. To the north of Battacolla a great portion of the soil is poor. About Beiluru are many groves of the tree from the seeds of which is expressed the common lamp-oil of the country. The

Canara.

climate of the lowlands is considered unhealthy, producing intermittent and other fevers.

The principal towns in North Canara are Cundapoor, Battacolla, Ancola, Carwar, Mirjaow, and Onore. The rivers by which the country is watered, from the short intervals between the country and the sea, are of no great magnitude, being generally mountain streams.

CANARA, SOUTH, is situated between the twelfth and fourteenth degrees of northern latitude; and is separated from the province of Malabar by a wide inlet of the sea. It is called Tulava by the Hindus, and South Canara by the British. It is a strip of land along the sea-coast, rising as it approaches the Ghaut Mountains; and the soil becomes gradually less adapted for grain as it recedes from the sea. The best in quality extends from Mangalore to Buntwalla. The banks of the river Mangalore, which in the rainy season is very large, are rich and picturesque; and the whole country resembles that of Malabar, only that the terraces on the sides of the hills have been formed with less care than in that district. Much of the rice land is so well watered by springs and rivulets, that it produces a constant succession of crops of that grain, one crop being sown as soon as the preceding one is cut. The second soil in point of quality is that which extends from Buntwalla to Punjalcutta, and the worst is that which extends from this place to the hills. There the rains are so excessive that they injure the crops of rice; but this inland portion of the country is very favourable for plantations. About Cavila, east of Mangalore, some of the hills are covered with tall thick forests, in which the teak tree abounds. From Urigara to Hopodurga the country near the sea is low and sandy, and too poor to produce even cocoa-nuts. This country has been dreadfully depopulated by the ravages of war. It suffered severely in its conquest by Tippoo. It had been previously shared among petty princes and numerous feudatories, who were all forced to retire before the armies of Tippoo, and to fly into the woods to avoid circumcision, a rite which was invariably forced upon them, in order to make them good Mohammedans; and it generally had this effect, for after suffering such an infliction from Tippoo, they lost their caste, and had therefore no alternative left. The inner parts of the country are much overgrown with woods, and very thinly inhabited.

The sugar-cane is cultivated on the low ground; but very small quantities only are raised. Between the rows are raised some cucurbitaceous plants, and kitchen stuffs that soon come to maturity. On the highest of rice land, where water may be had by digging to a little depth, capsicum is cultivated, as are also ginger and turmeric. The exports consist chiefly of salt, salt-fish, betel-nut, ginger, cocoa-nuts, cocoa-nut oil, and raw silk. The imports are chiefly cloths, cotton, thread, and blankets.

The chief inhabitants are Moplays (Mohammedans), who possess the sea-coast, as the Nairs do the interior. It is observed by Dr Buchanan, that the occupiers of land in this district are richer than those of Malabar; but he adds, that the universal cry of poverty which prevails all over India, and the care with which, owing to long oppression, every thing is concealed, render it extremely difficult to know the real circumstances of the cultivator. He concludes, however, from the obstinate contest which takes place for the possession of the land, that the cultivators have still a considerable interest in the soil. It appears, however, from the evidence of other collectors, that the inhabitants manifest in this way their regard to their paternal inheritance, for which they contend to the last; and when their interest as proprietors is lost in the increase of the assessment, they remain tilling the ground in the humble capacity of cultivators. There is no doubt that they never were so completely subdued by a foreign conqueror as the greater part of the Hindus, and always retained the title to their lands, which their rulers were never able entirely to take from them. When the province accordingly was conquered by the British, they found the landholders possessed of the clearest titles to their respective properties, which were recognised by the law of the country, as well as by immemorial usage. The chief towns of South Canara are Barcelore, Mangalore, and Callianpoor.

Canary Islands.

A number of Christians, to the amount of about 80,000, had been ordered to settle in this country by the ancient Hindu princes, with whom they had been in great favour. They were all of Concan descent, and had been instructed in the Portuguese and Latin languages, and in the doctrines of the Roman Church. About this period twenty-seven Christian churches existed in Tulava, each ruled by a vicar, and the whole under the control of a vicar-general, subject to the archbishop of Goa. Tippoo, when he conquered the country, proved himself to be the great persecutor of the Christian religion, throwing the priests into dungeons, destroying the churches, and forcing the laity to embrace the Mohammedan creed. After the conquest of the country by the British, many of these persecuted refugees returned and resumed their former faith; 15,000 came back to Mangalore and its vicinity; 10,000 made their escape from Tippoo to Malabar. These people are of quiet, sober, and industrious habits, and their superiority is acknowledged by the neighbouring Hindus. The Jain sect abound more in this province than in any other throughout India, and many of their temples are to be seen. Like other Hindus, they are divided into many sects, which cannot intermarry. (F. Buchanan's *Journey from Madras through the Countries of Mysore, Canara, and Malabar.* (D. B—N.) (E. T.)

CANARY ISLANDS (The) lie in the North Atlantic Ocean, between the parallels of Lat. 27. 40. and 29. 30. N., and the meridians of Long. 13. 30. and 18. 20. W. The names of the seven principal islands, their respective area in English square miles, and their population in 1835, are given in the following table:—

	Teneriffe.	Grand Canary.	Palma.	Lanzarote	Fuerteventura.	Gomera.	Hierro.
Area, .	877 7	758 3	718 5	323 5	326·1	169·7	82·2
Population,	85,000	68,000	33,000	17,400	13,800	11,700	4400

Fuerteventura lies nearest to the African coast, the interval being between 50 and 60 miles. Besides these, there are many islets, most of which are uninhabited.

History.—There is ground for supposing that the Phœnicians were not ignorant of the Canaries. The Romans, in the time of Augustus, received intelligence of them through Juba, king of Mauritania, whose account has been transmitted to us by the elder Pliny. He mentions "Canaria, so called from the multitude of dogs of great size," and "Nivaria, taking its name from perpetual snow, and covered with clouds," doubtless Teneriffe. Canaria was said to abound in palms and pine trees. Both Plutarch and Ptolemy speak of the Fortunate Islands, but their description is so imperfect that it is not clear whether the Madeiras or the Canaries are referred to. There is no farther mention of them until we read of their re-discovery about 1334, by a French vessel driven amongst them by a storm. A Spanish nobleman thereupon obtained a grant of them with the title of king from Clement VI., but want of means prevented him carrying out his project of conquest. Two expeditions subsequently set out from Spanish ports, and returned without having taken possession. At length three vessels, equipped by Jean de Bethencourt a gentleman of Normandy, sailed from Rochelle in 1400, and bent their course to the Canaries. He landed at Lanzarote and Fuerteventura, but being opposed by the natives, and finding himself deficient in means to effect his purpose, he repaired to the court of Castile; and obtaining from Henry III. a grant of the islands, with the title of king, he sailed in 1404 with a strong force, which mastered Lanzarote, Fuerteventura, Gomera, and Hierro,

without bloodshed. Being repulsed in his attempts on Palma and Canary, he returned to Europe in 1408 to obtain farther assistance. He was well received at the Castilian court, where he was promised the aid he sought; but he died shortly afterwards in France, whither he had gone to visit his patrimonial property. Bethencourt's nephew had been left governor of the islands, and claimed to succeed to his uncle's rights. Being charged with many acts of misgovernment, he went to Spain to clear himself, and whilst there sold his rights to Don Henrique de Guzman, who, after expending large sums in fruitless endeavours to reduce the unconquered islands, sold them to another Spaniard named Paraza. His successors, about 1461, took nominal possession of Canary and Teneriffe, but the natives effectually resisted their occupation of them. Meantime it appeared that Jean de Bethencourt's nephew had fraudulently made a second sale of the islands to Don Henry of Portugal, who sent 1000 men and 100 horse to take possession. The difference thus arising between the crowns of Spain and Portugal was ended by the cession of the islands to the former. Grand Canary, Teneriffe, and Palma remaining unsubdued in 1476, Ferdinand and Isabella of Spain compelled Paraza's successors to sell those islands to the crown; and the following year 1000 men were despatched to reduce them. After much bloodshed, and with reinforcements from the mother country, the Spaniards, under Pedro de Vera, became masters of Grand Canary in 1483. Palma was conquered in 1491, and Teneriffe in 1495, by Alonzo de Lugo. All the islands have continued in the possession of the Spaniards to this day.

Inhabitants.—As to the derivation of their original inhabitants nothing certain is known. The most probable supposition is, that they came from the adjoining coast of Africa. Pliny states that the islands were uninhabited at the time of which he wrote. If this were so, we might infer from the absence of any trace of Mohammedanism amongst the people found there by the Spaniards, that the migration took place between the time to which his account refers, and the time of the conquest of Barbary by the Arabs. They were called Guanches. Many of these people fell in opposing the Spanish invasion—many were sold by the conquerors as slaves—and many conformed to the Roman Catholic faith, and intermarried with the Spaniards; so that all trace of them as a distinct race is lost. They have always been celebrated for their tall stature, and Humboldt styles them the Patagonians of the old world. Spanish writings mention one chief who was 14 feet high, and another who measured 9 feet. Probably the Spaniards encouraged fables of this kind to magnify their conquest. The skeletons of eight or nine Guanche mummies were lately examined by Dr Hodgkin, who found them all to be less than average skeletons of Europeans. The Guanches embalmed the bodies of their dead, and placed them in caves. Many mummies have been found at different times in a state of extreme desiccation, each weighing not more than six or seven lbs. A recent traveller (Captain Grey) states, that there are two inaccessible caves in a vertical rock by the shore, three miles from Santa Cruz (Teneriffe), which still contain bones. A few words of the languages spoken by the ancient inhabitants have been preserved, and a resemblance of some of them to words of North African dialects has been noticed. On the other hand, the Guanches had customs, such as that of preserving their dead, in which they differed from the Berbers.

The present inhabitants are slightly darker than the people of the mother country; but in other respects scarcely distinguishable. The men are of middle height, well made and strong: the women are not striking in respect of beauty, but they have good eyes and hair. Spanish is the only language in use. The people have most of the traits of the people of the peninsula; they are sober, but given to gambling, quick, but lazy, faithless, and grossly superstitious. The lower classes are quite illiterate, and the better classes not very enlightened. A few booksellers' shops of a minor description exist at Santa Cruz and Las Palmas. At the former place two newspapers, and at the latter one, are published. Emigration to the extent of about 200 persons annually takes place to Cuba. The sustenance of the lower classes is chiefly composed of salt fish, potatoes, and *gofio*, which is merely Indian corn or wheat roasted, and then when ground mixed with water.

Government, &c.—The Archipelago is politically considered part of the province of Andalucia. The governor-general, who resides at Santa Cruz, has chief command both in civil and military affairs. The actual administration of affairs is in the hands of two lieutenant-governors, each with a district to himself, one of whom is resident at Santa Cruz, and the other at Las Palmas. On the other islands are deputy-governors, acting under the lieutenant-governor to whose district they belong. The military force is composed of a battalion of soldiers of the line, numbering about 1000 men; six regiments of militia amounting to about 8000 men, distributed amongst the islands; and a few companies of artillery. There is a military commander on each island. The great court of appeal sits at Las Palmas. Courts of first instance sit at Santa Cruz, Orotava, and Las Palmas. The laws of Spain are administered here. The land in great part is strictly entailed; the law of landlord and tenant is very bad. The islands form two bishoprics, Teneriffe, and Grand Canary. The whole ecclesiastical revenue is estimated at upwards of L.36,000. The monkish establishments have been suppressed, and such of the monasteries and convents as are not kept up for secular purposes are falling to ruin. No form of religion except the Roman Catholic is tolerated.

Climate and Meteorology.—From April to October a N. or N.E. wind of more or less strength blows upon these islands, commencing at 10 A.M., and continuing until 5 or 6 P.M. Foggy weather accompanies an easterly wind, but it becomes clear when the wind changes to the northward. On the S.W. coasts there is no regular sea or land breeze. In winter they are occasionally visited by a S.E. wind, called Levante. This is a hot wind from the African continent, producing various disagreeable consequences on the exposed parts of the person, besides injuring the vegetation, especially on the higher grounds. Locusts have sometimes been brought by this wind. In 1812, it is said that locusts covered some of the fields in Fuerteventura to the depth of four feet. Their last visit was in 1844. Hurricanes at distant intervals, accompanied by waterspouts, have caused much devastation; but, on the whole, these islands are singularly free from such visitations. The climate generally is mild, dry, and salubrious. On the lower grounds the temperature is equable, the daily range seldom exceeding 6°. On the mountains, of course, the range is greater, and the air much more cold and damp. The rainy season occurs at the same period as in southern Europe. The dry season is at the time of the trade-winds, which extend a few degrees farther north than this latitude. "In no part of the world is the barometer more susceptible of atmospheric changes than amongst the Canary Islands. A rapid rise is the sure precursor of an easterly wind, whilst the contrary as certainly indicates a change to W. or S.W." (Lieut. Arlett.)

Agriculture, Manufactures, and Commerce.—In ordinary years, sufficient grain and potatoes are produced to supply the wants of the islands. The soil on the lower part of the islands, where water is plentiful, is productive; in some places two crops of Indian corn and one of potatoes can be obtained from the same piece of ground in a twelvemonth. Except at Fuerteventura, the vine is much cultivated, but chiefly at Teneriffe, the best wines being produced on the N.W. coast. None, however, is considered so good as the wine of Madeira. The most esteemed kind is sent to Eng-

land under the name of Vidonia. The grape disease made its appearance at the Canaries in 1853, and destroyed nearly the whole crop. Previously the total annual produce was estimated at about 40,000 pipes, of which 25,000 pipes were produced in Teneriffe. Between 8000 and 9000 pipes were exported. The price per pipe on board ranged from L.8 to L.20. Some of the wine is distilled into good brandy. Sumach for the tanners, canary-seed, and a little flax, are grown. The gardens produce, in addition to the vegetables of English gardens, pumpkins, gourds, yams (taro), garlic, red pepper, and the castor-oil plant. The fruit trees are badly managed, so that the fruit is generally inferior. Here are found fruits from every quarter of the globe, including oranges, figs, bananas, dates, pine apples, pomegranates, papaws, guavas, custard apples, and prickly pears (the fruit of the cactus). There are no cocoa-nut trees or bread-fruit trees, as Humboldt reports. A little oil is obtained from the olive in Grand Canary. The agave is abundant, and supplies a material for ropes, girths, &c. The leaves of the date palm are made into hats and baskets. A good deal of orchilla-lichen is gathered for exportation; and the ice-plant is cultivated for barilla. The sugar manufacture, once so largely carried on, has fallen before the American and West Indian trade; the only two existing mills are on Palma. Wine having been for some time so little remunerative, other things have received attention, the chief of which is cochineal. This insect, which feeds on the common cactus (*Opuntia tuna*), is now largely produced on all the islands, land formerly occupied by grain and vines being devoted to its cultivation. The insect has not been long introduced, but the cultivation has rapidly extended. In 1849, 800,000 lb. were exported, principally to France and England. Since that year the exports have much increased; the price paid to the Canary exporter is about a dollar per lb. The silkworm is reared to a small extent, chiefly on Palma. Raw silk is exported, and some is manufactured on the spot into stockings, ribands, &c. Some linen and woollen stuffs of a coarse kind are made for home consumption, but the great bulk of the clothing in use is of British manufacture. The island goats (a peculiar and esteemed breed) furnish milk, from which butter and cheese are made. Sheep of a small coarse-woolled breed are numerous. Horses and cattle are scarce; domestic fowls and rabbits plentiful. Asses and mules are much used. A fishery on the African coast, at present engaging from 40 to 50 vessels, and giving employment to many persons, has existed since an early period. It was deemed of such importance, that the home government lately sent out a commissioner to report on it with a view to its improvement. The fish taken is principally bream. It is salted, and largely consumed at the Canaries.

There is a good deal of intercourse by means of boats and small sailing vessels amongst the different islands. In this way wine, raw silk, cochineal, barilla, and dried fruits are taken to the places of export; and grain is conveyed from those islands where it is abundant to those where the supply is deficient. The principal foreign trade is with England, the chief articles of export being wine, cochineal, barilla, and orchilla. The imports consist of iron, metal goods, glass, crockery, leather, silk, cotton, and woollen manufactures. There is also a considerable trade with the United States, and the countries bordering the Mediterranean. With Hamburg and France an exchange of commodities takes place. The ships employed in this commerce are foreign, chiefly British, but the islanders send a few vessels of their own with brandy, coarse earthenware, and silk goods to the Spanish West Indies, bringing back cigars, sugar, coffee, rum, cacao (the material of chocolate), and a few other articles. Santa Cruz, Orotava, and Las Palmas, are the only ports engaged in foreign trade; nearly 200 vessels enter these ports in the course of a year. In 1852, the ports were practically made free—the small duty of 2s. per cent. only being now levied upon imported goods, with the exception of tobacco, which pays 5d. per lb., and cigars which pay 10d. per lb. A Spanish steamer from Cadiz makes two voyages to Santa Cruz every month. The Spanish government packet on her outward voyage to Havannah touches at Santa Cruz once a month; and the same port is visited monthly by the English mail steamers to Brazil and the African coast, both on their outward and homeward voyages.

Zoology.—The indigenous animals, reptiles, and insects of the Canary Islands, are very few in number. As to mammals, only species of dog, of swine, of goat, and of sheep, were found upon the island by the Spanish conquerors. The race of large dogs which gave a name to Canary has been long extinct. A single skeleton was lately found and deposited in one of the museums at Paris. The ferret, rabbit, cat, rat, mouse, and two kinds of bat, have become naturalized. The ornithology is more interesting, both on account of the birds native to the islands, and the stragglers from the African coast. The latter are chiefly brought over in winter when the wind has blown for some time from the east. Amongst the former are some birds of prey, such as the African vulture, the falcon, buzzard, sparrow-hawk, and kite. There are also two species of owl, three species of sea-mew, the stockdove, quail, raven, magpie, chaffinch, goldfinch, blackcap, canary bird (green in its wild state), titmouse, blackbird, house-swallow, &c. The bird with the sweetest song is the capirote, a variety of *Sylvia atricapilla.* As to the insects, we need only mention a species of gnat or mosquito, which is sometimes troublesome especially to strangers, and the cockroach. The list of reptiles is limited to a small scorpion originally brought from the West Indies, a scolopendra, and the frog. The only fresh-water fish is the eel. The marine fishes are not numerous, the reason perhaps being, that the steepness of the coast does not allow of seaweed to grow in sufficient quantity to support the lower forms of marine animal life. M. Valenciennes states, that the fishes frequenting these coasts, like those of St Helena and Ascension, closely agree with the fishes of South America. Whales and seals are occasionally seen. Little is known as to the molluscs of these islands. Professor E. Forbes remarks, that the presence of *littorina striata*, a marine conchiferous mollusc, is a fact supporting the hypothesis that the Canaries, the Azores, the Madeiras, and the Peninsula, were once united. The cuttle fish is abundant, and is sought for as an article of food.

Botany.—The position of mountainous islands like the Canaries, in the sub-tropical division of the temperate zone, is highly favourable to the development within a small space of plants characteristic of both warm and cold climates. Von Buch refers to five regions of vegetation in Teneriffe. 1. From the sea to the height of 1300 feet. This he styles the African region. The climate in the hottest parts is similar to that of Egypt and southern Barbary. Here grow amongst the introduced plants the coffee tree, the date palm, the sugar-cane, the banana, the American agave, and the cactus; and amongst indigenous plants, the dragon tree on the N.W. of Teneriffe. A leafless and fantastic euphorbia, and a shrubby composite plant, *Cacalia Kleinia*, give a character to the landscape about Santa Cruz. 2. Between 1300 feet and 2800 feet is the region of South European vegetation, the climate answering to that of southern France and central Italy. Here flourish the vine and the cereals. 3. The region of indigenous trees, including various species of laurel, an *Ardisia*, *Ilex*, *Rhamnus*, *Olea*, *Myrica*, and other trees found wild also at Madeira. The clouds rest on this region during the day, and by their humidity support a vegetation amongst the trees, partly of shrubs, and partly of ferns. It extends to the height of 4000 feet. 4. The region of the *Pinus canariensis*, extending to the height of 6400 feet: the broad-leaved trees

Canary Islands.

have ceased to grow, but arborescent heaths are found in its whole extent, and a few specimens of *Juniperus oxycedrus* may be met with. 5. The region of Retama, (*Spartium nubigenum*), a species of white-flowering and sweet-scented broom, which is found as high as 11,000 feet. At the upper edge of this region a violet clings to the soil, and above there is nothing but a little lichen. The number of indigenous phanerogamous plants may be estimated at between 700 and 800, upwards of 160 of which are peculiar to the Canaries. The forms of vegetation must in the main be considered North African, since the origin of many of those which they have in common with southern Europe should be looked for in Africa. The character of the vegetation in Lanzarote and Fuerteventura islands, composed of extensive plains and low hills, with few springs, is different from that of the other islands, which are more elevated and have many springs. The wood is more abundant, and the vegetation more luxuriant.

Geology.—The lower and exterior portion of these islands consists for the most part of basalt, compact, vesicular, or scoriaceous, interstratified with beds of variously coloured tufa. In some cases the rock is chiefly trachyte. The basalt presents an abrupt and precipitous face to the sea. The compact variety frequently contains scattered grains and crystals of augite and olivine. In Teneriffe, the basalt and tufa form an exterior mass, through which in the centre emerge the felspathic or trachytic rocks forming the nucleus of the volcanic cone, and over them fragments of pumice and streams of modern lava have been thrown. These trachytic rocks contain numerous disseminated crystals of glassy felspar. The few minerals that have been found in the Canary Islands are those characteristic of volcanic regions. A little iron exists, but is not turned to account. In no part of Teneriffe has there been discovered any sedimentary rock. The old lavas in Lanzarote are covered by a thin layer of white concretionary limestone, the origin of which is obscure. In Grand Canary and Fuerteventura there is also calcareous stone, but its nature does not appear to be known. It has long been conjectured that the Canaries, the Azores, and the Madeiras, were once connected with each other, and with the continents of Europe and Africa. Recent investigations seem to yield results that give some colour to the hypothesis.

Teneriffe, the largest island of the group, lies between Canary and Gomera. It is of an irregular shape, 60 miles in length, with an extreme breadth of 30 miles. Not more than one-seventh is cultivable. A chain of mountains traverses the island in the direction of its greatest length, and in the middle of the broadest part rises the celebrated peak locally known as the Pico de Teyde, which, with its supports and spurs, occupies nearly two-thirds of the whole island. It has a double top; the highest, El Piton, is 12,180 feet above the sea; the second, Chahorra, connected with the first by a short narrow ridge, has a height of 9880 feet. They are both orifices in the same grand dome of trachyte. Neither reaches the line of perpetual snow. There is, however, a natural cavern, 11,000 feet above the sea, where snow is preserved all the year. Snow remains about four months on the upper part of the peak.

For more than one-half of its circumference the base of the true peak rises from an elevated but comparatively level tract called by the Spaniards *El Llano de la Retama* (*retama* is a local name for the *Spartium nubigenum* which abounds there), and by the English the Pumice-Stone Plains. Three miles from the base of the cone, on the S.E., south, and S.W., there is a high ridge overlooking the Pumice-Stone Plains, and presenting a very steep face to the peak. Between the ridge and the sea the slope is more gradual, and there are intervening table-lands. Peaks rise from the ridge, one of which attains the height of 9400 feet. The aspect of this ridge, the Llano, and the cone, is described by Von Buch as resembling a fortress with ramparts and a foss. He says that there would be a similar rampart on the N.E., north, and N.W., had not comparatively late eruptions filled up the foss. The peak, then, is a pile of lava, trachyte, and ashes, thrown up, either in an immense rent, where older volcanic rocks, consisting principally of basalt and tufa, have been torn asunder, or in an ancient crater which had become greatly enlarged. Both El Piton and Chahorra have craters on their summits, from which issue steam and a little sulphureous vapour, forming what is called a solfatara. The crater (*Caldera*) on El Piton is surrounded by a wall of lava which would prevent access to the interior if it were not broken away on one side. The lava of the interior has been made white by the action of sulphureous vapours, and every crevice contains crystals of sulphur. The thermometer rises considerably when thrust into the ground. It is not perfectly circular; its dimensions are given as 300 feet across in one direction, and 200 feet in another, with an average depth of 100 feet. It takes more than an hour to walk round the crater on Chahorra, but its depth is scarcely 150 feet. The view from the highest point, when no clouds intervene, is very extensive. All the islands of the Archipelago are visible, and the horizon is 140 miles distant. The coast of Africa and the island of Madeira are not within the range of vision. Pico Ruivo, the highest peak of Madeira, must be three times higher than it is to bring it into view. Humboldt estimates the height of the peak to be $\frac{1}{28}$th of the circumference of its basis, and he says that if the slope were uniform from the summit to the base, it would have an inclination of 12° 29′. The steepest part of the cone has an inclination of 40°.

The ascent of the peak is usually made from Orotava, on the northern side of the island. After leaving the cultivated grounds, a belt of chesnut trees is crossed, and then the regions of arborescent heaths and ferns, as far as a pass (Portillo) which admits the traveller between two basaltic hills (part of the rampart above spoken of), into the *Llano de la Retama.* The scenery here is in striking contrast with what it has previously been. Instead of a steep and rugged ascent among black basaltic rocks, the traveller enters upon gently sloping ground, covered to a considerable depth with white pumice gravel, amongst which spring tufts of *spartium.* The tender shoots of this shrub serve the wild goats for food, and the flowers yield a rich honey to the bees. The entrance to the Llano is nearly 8920 feet above the sea. Between two and three hours are consumed in crossing the Llano to the base of the cone, the lower part of which (*Monton de Trigo*) is ascended to a point 9750 feet above the sea, called *Estancia de los Ingleses* (Englishmen's station), where the mules must be left, and where travellers frequently pass the night. The rest of the way is very steep and fatiguing, the cone being here composed of loose stones, ashes, and pumice, upon which narrow streams of obsidianic lava are laid like black ribands. The pumice is in such quantity, that at a distance it has the appearance of snow coating the peak. From 20 to 24 hours are consumed in ascending the peak and returning to Orotava.

To the N.W. of the grand cone, some thousands of feet below Chahorra, there are many small cones of eruption, showing that the intensity of volcanic action was greatest on this side. Eastward from the ridge bounding the pumice-stone plain, extends a chain of mountains to the north-eastern extremity of the island. The highest peaks are Izana, 7374 feet; Perexil, 6027 feet; and Cuchillo, 5467 feet. The road from Santa Cruz to Orotava crosses the chain at a point near Laguna, where it is less than 2000 feet high.

We have no account in history of eruptions from either crater of the peak. In 1795 a great quantity of lava was poured out from three vents on its eastern side; and in the same year lava streams issued from a crater near Guimar,

Canary Islands.

half way between Santa Cruz and the peak. In the following year, a vent on the north-western side of the peak discharged a copious stream, which flowed down to the sea, and nearly filled up the harbour of Garadrico. For three months in 1798, much lava and other volcanic matter was ejected from orifices to the west of Chahorra.

Santa Cruz de Santiago, on the south coast, is the residence of the governor-general of the Canaries, the civil lieutenant-governor of the Teneriffe district, and the military governor of the island. Its position is N. Lat. 28. 28. 30., and W. Long. 16. 16. 0. It is a well-built and tolerably clean town of 9000 inhabitants, lying on a strip of level ground, at the foot of a vertical wall of black barren rocks. Scarcely any vegetation except thorny cactuses and euphorbias is to be seen in the neighbourhood. The streets are at right angles to each other, narrow, but provided with side walks. There are three public squares. The houses are generally low, with flat roofs; those of the better class are large, with a court-yard in the middle, planted with shrubs in the Spanish fashion. The market is well supplied with meat, fruits, and vegetables. Good water is brought from a distance, passing at one part of its course along an aqueduct 180 feet in length, with a depth of cut of 120 feet. A British consul resides here, as well as four or five English families. The accommodation for strangers is neither plentiful nor good. The Spanish cloak is much worn by the men, and the white mantilla by the women. Dromedaries, though not bred on the island, are in use for the conveyance of merchandise, and in agricultural operations. They are brought from Lanzarote and Fuerteventura. A good animal costs from 30 to 40 dollars. A few wheel-carriages are in use. Much ground in the neighbourhood is planted with cactus (*Opuntia tuna*) for the support of the cochineal insect. The town is defended by several batteries; and it was by a shot from one of these that Lord Nelson lost his arm, when he unsuccessfully attacked the place in 1797. Some of our flags lost on that occasion are still hanging in one of the churches. The anchorage is good, and landing is assisted by a mole. About 100 vessels annually visit the port. The climate is dry and temperately warm, the annual mean being 71° Fahr. The mean of the coldest month is 63°·8 F., and of the hottest 78°·8 F. Rain falls on an average on 36 days in the year.

Laguna (pop. 10,000), the capital of the island, and the seat of the political, judicial, and ecclesiastical establishment, stands at the distance of four miles from Santa Cruz, in the centre of a plain where much grain is produced, elevated 1725 feet above the sea, and nearly surrounded by mountains. The situation is beautiful, but the town itself is gloomy. Here are several deserted convents, and a cathedral. In summer the temperature is refreshingly cool, and for that reason Laguna is then resorted to by the rich of Santa Cruz. In winter it is cold and damp, the plain being frequently laid under water by rain. The mean temperature of the year is 63°·2 Fahr. Snow has never been known to fall here. The humidity of the atmosphere is shown by the numbers of semperviva growing on the houses and walls.

The road from Santa Cruz to *Orotava*, 25 miles distant, lies through Laguna and Matanza—a place deriving its name from an overthrow received by the invading Spaniards from the Guanches in 1494. All travellers speak in terms of warm admiration of the scenery in this part of the island. Humboldt's words are: "Under the torrid zone I found sites where nature is more majestic, and richer in the display of organic forms; but, after having traversed the banks of the Orinoco, the Cordilleras of Peru, and the most beautiful valleys of Mexico, I own that I have never beheld a prospect more varied, more attractive, more harmonious in the distribution of the masses of verdure and of rocks, than the western coast of Teneriffe." The town of Orotava is 1040 feet above the sea. It contains about 8000 inhabitants. The houses are solidly built, but it has a deserted aspect. A stream of water is conducted through every street. The famous Dragon-tree grows in the garden of of the Marquis of Sanzal. It is quite hollow, and is a mere wreck of what it has been. It has a height of between 50 and 60 feet, the circumference just above the roots is nearly 48 feet, and the opening into the interior is 13 feet wide.[1] *Port Orotava*, three miles from the villa, is a clean place, with between 4000 and 5000 inhabitants, amongst whom are three or four English families. The streets are broad, and the houses well built. The roadstead, protected by a fort and some batteries, affords little or no shelter against wind. The botanic garden, founded by a patriotic Spanish nobleman, has gone to ruin since it came into the possession of the government. *Icod de los Vinos*, a pretty town of 4000 inhabitants, farther to the west in a fertile district, has a manufacture of silk, but it is not flourishing. There are several other towns on the island, but none so large as these. They stand principally on the N.W. side, not far from the coast. The highest inhabited place is Chasna, on a plain more than 4000 feet above the sea, to the south of the peak.

Grand Canary (*Gran Canaria*), the most fertile island of the group, is nearly circular in shape, with a diameter of 24 miles, and a circumference of 75 miles. The interior is a mass of mountain, with ravines radiating to the shore. Its highest peak, Los Pexos, is 6400 feet above the sea. Large tracts are covered with native pine (*P. canariensis*). There are several mineral springs on the island. From the nature of the ground, only a small part is under cultivation. The fishery on the African coast gives employment to a large number of persons. Las Palmas (pop. 10,000), the seat of the local government, is a well-built and clean town in a small bay on the east coast. It contains a handsome cathedral, a hospital, a college, several secularized convents, and an alameda or public walk. Its climate is more humid than that of Santa Cruz. Water is brought into the principal streets and squares by an aqueduct. The harbour, Puerto de la Luz, affords good anchorage and shelter against all winds except the S.E. It is formed by a rocky peninsula (*Isleta*), connected with the mainland by a low neck of land. The mole is still unfinished. Several forts defend the bar and harbour. A British vice-consul resides here. In 1851 the cholera visited the island, and 9000 persons died. Not a single case occurred on any other island. Telde, the second place in the island, stands on a plain surrounded by palm trees. At Atalaya, a short distance from Las Palmas, the making of earthenware vessels employs some hundreds of people, who inhabit holes made in the tufa.

Palma (correctly, San Miguel de la Palma) is 26 miles long, with an extreme breadth of 16 miles. It lies 67 miles W.N.W. of Teneriffe. Its shape is somewhat like that of a pear. It is traversed in its longest direction (north to south) by a chain of mountains, the highest of which is 7900 feet above the sea. At the broadest part is a crater nine miles in diameter, known as the Caldera (*i.e.* cauldron), from which, on its S.W. side, runs a ravine to the sea. The bottom of the crater has an elevation above the sea of 2300 feet, and it is overhung by peaks that rise more than 5000 feet above it. Some of these peaks are covered with snow for several months in the year. Extensive woods, principally composed of chestnut and pine, lie on their flanks. Palma contains several mineral springs, but there is great want of fresh water. The only stream which is never dried up is that which issues from the Caldera. In 1677 an eruption, preceded by an earthquake, took place from a vol-

[1] Humboldt in describing it says—"Among organized beings this tree is undoubtedly one of the oldest inhabitants of our globe. It is remarkable that the *Dracæna Draco* is not a native of these isles nor of Africa, but of Eastern Asia. How at a remote period it came to this island is a matter of curious speculation."

cano at the southern extremity of the island, and much damage was done by the ejected ashes, stones, and lava. The sugar-cane is grown on an elevated plain called Los Llanos. Ribands and stockings are manufactured from silk produced on the island. The poor make much use of the roots of the *Arum colocasia* to mix when ground with flour. Grain is imported. Sheep, goats, and cattle are numerous. Santa Cruz, on the eastern coast, is the principal town; it has 6000 inhabitants. The anchorage is good. The cultivated soil is fertile, but the labouring classes are in a wretched condition notwithstanding their industrious habits. The enormous dimensions of the Caldera are supposed by Sir C. Lyell (on the facts supplied by Von Buch) to have resulted from the action of the sea, exerted as the island was slowly lifted upwards by subterranean forces from beneath the waves. The cone, which, according to Von Buch, is composed of alternating beds of basalt and conglomerates pierced by basaltic dikes, had been previously formed by a long series of volcanic eruptions; and the great ravine may have been caused by the sea entering the crater at the lowest point of the rim, and cutting a passage for itself that went deeper and deeper as the mountain was pushed up. The exterior of the cone is seamed by ravines that radiate on all sides towards the sea, but none penetrate the Caldera except the single one already mentioned.

Lanzarote, the most easterly of the group, has a length of 31 miles, and a breadth varying from 5 to 10 miles. It is naked and mountainous, bearing everywhere marks of its volcanic origin. Montaña Blanca, the highest point, attains a height of 2000 feet, and is cultivated to the summit. In 1730 the appearance of half the island was altered by a volcanic outburst. A violent earthquake preceded the catastrophe by which nine villages were destroyed. In 1825 another volcanic eruption took place, accompanied by earthquakes, and two hills were thrown up which still emit smoke. The port of Naos on the S.E. of the island affords safe anchorage. It is protected by two forts. A short distance inland is the town of Arecife, with a population of 2500, where a British vice-consul resides. The climate is hot and dry. There is only a single spring of fresh-water on the island, and that is in a position difficult of access. From the total failure of water the inhabitants were once compelled to abandon the island. The inhabitants are now chiefly employed in agriculture, in the fishery off the African coast, and in the callings to which the fishery gives rise. Grain, wine (which is of superior quality), brandy, barilla, orchil, and raisins made from the muscatel grape, are the principal articles of export. The cattle are small, and horses few. Dromedaries are used as beasts of burden. Teguise on the N.W. coast is the residence of the local authorities, and has a population of 1000. A strait of about 6 miles in width separates Lanzarote from Fuerteventura.

Graciosa, a small uninhabited island, is divided from the north-eastern extremity of Lanzarote by a channel a mile in width, which affords the most capacious and only safe harbour for large ships at the Canaries; but basaltic cliffs 1500 feet high prevent intercourse with the inhabited part of Lanzarote. Forty persons reside on the little island Allegranza, a mass of lava and cinders ejected at various times from a now extinct volcano, the crater of which has still a well-defined edge.

Fuerteventura lies between Lanzarote and Grand Canary. It has a length of 52 miles, and an average width of 12 miles. Though less mountainous than the other islands, its aspect is barren. The springs of fresh water are only two, and they are confined to one valley. The larger vegetation is composed of an inconsiderable number of date palms, and fig trees. Lava streams and other signs of volcanic action abound, but there have been no signs of igneous activity since the Spaniards took possession. At each of its extremities are high mountains which send off branches along the coast so as to inclose a large arid plain. The highest peak is in the peninsula of Handia; it is 2500 feet in height. In external appearance, climate, and productions, this island greatly resembles Lanzarote. An interval of three years without rain has been known. The inhabitants are poor and indolent, but a strong and well-built race. Various kinds of grain and potatoes are cultivated. The wine is bad. Barilla and orchilla are largely exported. Oliva is the largest town; it has 2000 inhabitants. A smaller place in the centre of the island named Betancuria is the residence of the authorities. Cabras, on the eastern coast, with a population of 1000 persons, is the chief port. Goats are numerous. Dromedaries are bred here. The peninsula of Handia, a mass of high mountains that presents a precipice to the N.W., and a steep slope furrowed by ravines to the S.E., is joined to the rest of the island by a low isthmus of sand. This peninsula affords pasturage to many herds of cattle and goats. Much orchilla is collected here.

Gomera lies 20 miles S.W. of Teneriffe. Its shape is rudely triangular. The longest straight line that can be drawn in it is about 23 miles long. Its coast is precipitous and its interior mountainous, but it is the most wooded and best watered of the group. The inhabitants are deeply impoverished and half-famished. Wine, brandy, orchilla, raw silk, and dried fruits are sent to Teneriffe. Dromedaries are bred on Gomera, and there are thousands of them here. St Sebastian, the chief town and a port, has 1000 inhabitants. Columbus resided here before sailing in quest of the New World.

Hierro or *Ferro*, the most westerly and the smallest island of the group, is somewhat crescent-shaped. Its length is about 18 miles, its greatest breadth about 15 miles, and its circumference probably 50 miles. It lies 92 miles W.S.W. of Teneriffe. Its coast is bound by high steep rocks, which only admit of one harbour, but the interior is tolerably level. Its hill-tops in winter are sometimes wrapped in snow, which however does not lie long. Better and more abundant grass grows here than on any of the other islands. The island is exposed to westerly gales which frequently commit great damage. There is here a sulphureous spring, the water of which has a temperature of 102° F. The springs of fresh water are few. The once celebrated and almost sacred Til tree, which was reputed to be always distilling water from its leaves in sufficient abundance to fill two large tanks, no longer exists. Only a small part of the cultivable land is under tillage, the inhabitants being principally employed in pasturage. Wine, brandy, orchilla, excellent dried figs, and sheep, are sent to Teneriffe. At Valverde, the principal town, the local authorities reside. Geographers were formerly in the habit of measuring all longitudes from Ferro. (J. Y. J.)

CANARY-BIRD. See ORNITHOLOGY.

CANCALE, a seaport-town of France in the department of Ille-et-Vilaine, 10 miles east of St Malo, on the bay of St Michael. A considerable trade is carried on in oysters, which are found in the bay in great numbers and of excellent quality. Pop. about 3000.

CANCAO or CANCAR, a seaport-town of Cambodia, situated on the gulf of Siam, in N. Lat. 10. 18., E. Long. 105. It carries on a considerable trade in iron and the more valuable kinds of timber, but has of late years begun to decline.

CANCELLI, a term used to denote windows made of cross bars disposed latticewise. It is also used for rails or balusters, and for the net-work in the inside of hollow bones.

CANCER, a glandular disease, unfortunately of comparatively too frequent occurrence. It appears as a roundish, hard, unequal, schirrous tumour, which usually ulcerates, is attended with much pain, and generally terminates fatally.

CANCER, in *Astronomy*, one of the twelve signs, represented on the globe in the form of a crab, and in books marked

thus, ♋. The reason generally assigned for its name, as well as figure, is a supposed resemblance which the sun's motion in this sign bears to that of the crab-fish. As the latter walks backwards, so the former, in this part of his course, begins to recede; though others suppose the disposition of stars in this sign to have given the first hint of the representation of a crab.

Tropic of Cancer, in *Astronomy*, a lesser circle of the sphere, parallel to the equator, and passing through the beginning of the sign Cancer.

CANCHERIZANTE, or Cancherizato, in the Italian music, a term signifying a piece of music that begins at the end, being the retrograde motion from the end of a song, or other composition, to the beginning.

CANDACE, or Kandāke, a queen of the Ethiopians, mentioned in Scripture, Acts viii. 27. We learn from the testimonies of various profane authors that Ethiopia Proper was for a considerable period under the sway of female sovereigns, who all bore the appellation of *Candace;* so that it appears to have been merely a distinctive title, like Pharaoh, Ptolemy, or Cæsar. (See Plin. *H. N.* vi. 29.)

CANDAHAR, or Kandahar, an extensive province of Afghanistan, situated between the 31st and 34th degrees of north latitude, and between the 62d and 68th degrees of east longitude. To the north it is bounded by the country of Balk, to the south by Beloochistan, on the east it has Scinde and Beloochistan, and on the west a sandy desert of various breadth divides it from the province of Seistan, in Persia. Part of this province consists of mountains, and part of arid and uncultivated plains, crossed by ranges of hills running westward from the Paropamisan mountains. But though the general appearance of the country be waste and barren, most parts of it supply water and forage to the pastoral hordes by whom it is frequented; and it is not destitute of many well-watered and pleasant valleys, and some fertile plains, surrounded by mountains. The western part of this tract is by no means so mountainous as the northern; and in former times it was a fertile and well-inhabited region, as appears from many magnificent ruins that are scattered over it. From Candahar a tract of very considerable extent stretches westward for upwards of two hundred miles. Its general breadth is a hundred miles. This tract is very imperfectly defined, the hills on the north sometimes running into the plain, and the southern parts of the inhabited country not being easily distinguished from the desert on which they border. The aspect of this country approaches to that of a desert. Scarce a tree is to be found in the whole region; the plains are covered merely with low bushes. Through this arid region many various streams diffuse occasional fertility. The banks of the Furrah, the Khaush, and other streams, are well cultivated, and produce wheat, barley, pulse, and abundance of excellent melons. Even at a distance from the streams some patches of cultivation are to be found, which are artificially watered. There are villages among the cultivated lands; but the mass of the inhabitants are scattered over the face of the country in tents. The banks of the Helmund must, however, be excepted from the general unproductive character of the country, along which a fertile strip extends about two miles in breadth, beyond which the sandy desert begins, and stretches out for many days' journey. To the northward of this desert tract is a hilly region, dependent on the Paropamisan range, which includes fertile plains, that are well watered and produce abundance of wheat, barley, and rice, together with madder and artificial grasses. On these plains grow the tamarisk and the mulberry, and a few willows and poplars; and the orchards contain all the fruit trees of Europe. The country around the city of Candahar is level, of tolerable fertility, irrigated both by water courses from the rivers and by springs, and most industriously cultivated. It abounds in grain, good vegetables, excellent fruit; in madder, assafœtida, lucerne, clover, and tobacco, which is in very great repute.

The wild animals of this country are leopards, bears, wolves, hyenas, jackals, foxes, deer, hares, boars, and the wild ass. The tame animals are camels, horses, cattle, mules, asses, sheep, goats, dogs, &c. There are also a few buffaloes. The country produces no metals, nor has it any peculiar manufactures. But as the road between India and Persia passes through it, it has a considerable transit trade. Besides the Dooraunees, one of the chief tribes of the Afghan country, there are in Candahar Hindus, Persians, Belooches, and Taujiks. The Taujiks generally inhabit towns, and follow different trades. The bankers and shop-keepers are all Hindus.

Candahar, the capital of the above province, and a large and populous city. Its form is that of a square or oblong; and as it was built at once on a fixed plan, it has the advantage of great regularity. All the four great streets or bazaars in the city meet in a central point, where there is a circular space of about forty or fifty yards in diameter, covered with a dome. This place is called the Chaursoo. It is surrounded with shops, and may be considered as the public market-place, where proclamations are made, and where the bodies of criminals are exposed to the view of the populace. The four streets are each about fifty yards broad. The sides consist of shops of the same size and plan, all one storey in height, with the lofty houses of the town overlooking them from behind; and in front runs an uniform veranda, along the whole length of the street. There are gates at the entrance of the streets, with the exception of the northern one, where stands the king's palace facing the Chaursoo. All the other streets run from these four; and though they are narrow, they are all straight, and almost all cross each other at right angles. This city, however, though it is more regular in its plan than most of the cities of Asia, has but a mean appearance, being built for the most part of brick, often with no other cement than mud. It is divided into various quarters, which are attached to the respective tribes and nations which form the inhabitants of the city. Almost all the great nobles of the Dooraunee tribe have houses in Candahar, and some of them are said to be large and elegant. Among the common people the Hindus have the best houses, which they are in the practice of building very high. There are many caravanserais and mosques; but of the latter, one only near the palace is said to be handsome. The palace is not remarkable; but it contains several courts, many buildings, and a private garden. Near the palace stands the tomb of Ahmed Shah, which is not a large building, but has a handsome cupola, and is elegantly painted, gilt, and otherwise ornamented within. Twelve smaller tombs of the children of the deceased shah are ranged about the principal one, and many texts of the Koran strewed around afford solemn impressions to the Mohammedan visitors. An establishment of Moollas is attached to the tomb, and one of their number constantly attends in the building. The city is well watered by two large canals from the river Urghundaub, which are crossed in different places by small bridges. From these canals small water-courses run to almost every street in the town, which are in some parts open, and in others are under ground. Candahar is a place of great resort: its principal business arises from the transit trade, which brings a large number of foreigners in proportion to the resident population. Hence there is a surprising diversity of costumes in the bazaars. The Turcoman merchants from Buckhara and Samarcand frequent the markets of Candahar, whence they transport into their own country a considerable quantity of indigo and other commodities. Candahar so far differs from the other cities in Afghanistan, that the greater part of the inhabitants are Afghans, and of these the greater number of

the Dooraunee tribe. The other inhabitants are the same as those in the province, being an assemblage from the different nations of the East. Candahar is surrounded with gardens and orchards, and many places of worship, which are more frequently scenes of pleasure than of devotion. About two miles to the north of the city stands the fortress of Candahar, on the top of a precipitous rock, which, before the introduction of cannon, was considered impregnable. This fortress was in very early times the residence of a Hindu prince. In the beginning of the eleventh century it was in possession of the Afghan tribes, from whom it was taken by Sultan Mahmoud of Ghizne. It was afterwards captured by the troops of Ghenghis Khan in the beginning of the thirteenth century, and by those of Timour in the fourteenth. In 1507 it was taken by the Emperor Baber, but was soon afterwards recovered by the Afghans. In 1521 Baber again got possession of it, after a long siege. Homayon, the son of Baber, when he was expelled from the throne of Hindustan, agreed to make over the fort and district of Candahar to the Persian monarch, in return for the aid which he gave them. But repenting of his promise, he again got possession of the fortress, which by its strength defied all the efforts of the Persians to reduce it. It remained an appendage of Hindustan until the year 1625, when it was taken by Shah Abbas the Great, and being surrendered by treachery, was recovered in 1649, and was successfully defended against Aurungzebe with an army of 50,000 men. Three years after, he was again compelled to retreat from it with disgrace. It remained in possession of Persia till 1709, when it was taken by an Afghan tribe. It was retaken by Nadir Shah, after a siege of two years; and on his assassination, it was taken in 1747 by Ahmed Shah, the chief of the Abdallies, who thereby laid the foundation of the Afghan power. Under Ahmed Shah, Candahar was the seat of government, which was removed to Cabul by his successor. On the dismemberment of Afghanistan, subsequent to the expulsion of Shah Shooja, the brothers of Dost Mahomed established themselves in Candahar, and levied contributions over the neighbouring districts. Their weak and pernicious rule was terminated by the occupation of their capital by a British force in 1839. The army of occupation, notwithstanding the frequent and desperate attacks of the natives, made good the defence until the autumn of 1842, when it finally evacuated the place, and commenced its triumphant march on Ghuznee and Cabul. Lat. 31. 37., Long. 65. 28. See Afghanistan.

CANDAULES, called also Myrsilus, king of Lydia, was assassinated by his favourite Gyges, at the instigation of the queen, who took this revenge because her husband, through excess of vanity, had secretly exhibited to that officer her naked charms. She then married the murderer, who mounted the throne, B.C. 715. (See Herod. i. 7–13; Justin, i. 7; Plat. *De Repub.* ii., p. 359.)

CANDELABRUM, a high and ornamental kind of candlestick or stand for lamps. The candelabra of the ancients were frequently very magnificent, combining exquisite design with admirable workmanship. They were generally made of bronze, but sometimes of marble, &c. Perhaps the finest collection of ancient candelabra is to be seen in the museum of the Vatican.

CANDESH. See Khandesh.

CANDIA (the ancient Crete), an island in the Mediterranean, S.W. from the Morea, and extending from 34. 55. to 35. 42. N. Lat., and from 23. 30. to 26. 20. E. Long. Its extreme length is about 160 miles; in breadth it varies from 6 to about 45 miles. It is traversed from east to west by a range of hills, the highest of which, Psilorati (the ancient Ida), rises to an elevation, according to Sieber, of 7674 feet, and is capped with snow till midsummer. Its sides are steep and cavernous. On the S.W. are the White Mountains, which descend almost to the coast, and are infested by the Sphakiotes, a tribe of native banditti and pirates, who have defied all the efforts of the Turks to exterminate or subdue them. The northern coast of the island is deeply indented with bays, which are protected by the headlands of numerous offshoots from the central chain, and afford tolerably good anchorage. The ports and principal towns of Candia are ranged along this coast at the entrance of the valleys, which form the only accessible points from the sea. The southern coast is precipitous and inaccessible. The climate in the uplands of Candia, where the rain is rapidly drained off by the mountain torrents, is exceedingly good; but the low grounds in autumn are often flooded and rendered unhealthy by exhalations. The mountains on the north are covered with forests, and afford pasture for sheep, goats, and black cattle, besides being abundantly stocked with game. The soil of the valleys, though highly fertile, is too light for the cultivation of grain, which the inhabitants are obliged to import in considerable quantities from Egypt and Barca. The principal source of profit to the inhabitants is derived from the culture of the olive, and the extensive manufacture of oil and soap, which form the staple of their exports. There is an inconsiderable trade in wine, silk, flax, and cotton; but the oppressive exactions of the Turkish government are gradually diminishing the industrial resources of the island. Linen, woollen, and cotton stuffs, are generally manufactured only for domestic use. The peasantry are a rude and uncultivated race, and their mode of agriculture barbarous in the extreme. No trace has been found of the iron mines which are said to have existed here. The island is divided into eight bishoprics, belonging to the Greek church; the metropolitan resides at the capital. For the purposes of administration, it is divided into the three provinces of Candia, Retimo, and Canea, which are governed by distinct civil officers under the Turkish viceroy of Egypt. The population of Candia is estimated at 163,000, of which by far the greater part consists of Greek Christians.

The golden age of Candia, if we except the fabled reign of Saturn in the island, was during its subjection to the Venetians, to whom it was sold by the Byzantines in 1204. Notwithstanding the prolonged and vexatious resistance of the Sphakiotes to the Venetian governors, the inhabitants were placed under a popular administration, and enjoyed for nearly four centuries the greatest political and religious freedom. With very little foreign aid, they continued to repel the hostile invasions of the Genoese and Turks till the middle of the seventeenth century. In 1644 began the contest between the Venetians and Turks for the occupation of Candia, which lasted for nearly 25 years, and resulted in the transference of the island into the hands of the latter. The Candiots were assisted by grants of money from the Western powers, and reinforced by bands of French, German, and Maltese crusaders, who sallied out against the Turks at the especial command of the pope. The resources of so small an island could not, however, long hold out against the overwhelming numbers of the besiegers; but it was not till nearly 31,000 Christians had been slain on the ramparts and in sorties, and the fortifications were crumbling to pieces under the severe cannonade, that the town of Candia was surrendered to the enemy in 1669. Since that time Candia has never regained its commercial prosperity, and the inhabitants have been involved in perpetual contests with the Turkish government. In 1830 the Turks were compelled by the European powers to cede it to the pacha of Egypt, but it was again restored to Turkey in 1840; and the improvements in the island, which in the interval Mehemet Ali had projected and begun, were frustrated by an unsuccessful rebellion, which broke out in the following year.

Candia, the capital of the above island, is situated about the centre of its northern shore, in N. Lat. 35. 20., E. Long. 25. 9. It was once a strongly fortified seaport, but its de-

fences have been allowed to fall into disrepair, and the harbour, which was formed by a mole, is so choked with sand as to be inaccessible to vessels drawing more than 8 feet of water. The houses of the Turkish residents are well-built and pleasantly adorned with gardens, but the rest of the town is somewhat dilapidated and ruinous. The principal buildings are the pasha's palace, the bazaars, the mosques, and the public baths. Candia is the residence of a Greek archbishop, and contains a large cathedral which was founded by the Venetians. Its principal trade is in oil and soap: its exports and imports are conveyed almost exclusively in Greek and Turkish bottoms. Pop. 12,000.

CANDIAC, Jean Louis Pierre Elizabeth de Montcalm de, a child of astonishing precocity, born at the château de Candiac in the diocese of Nismes in France, in 1719. At four years of age he read Latin, either printed or in manuscript; and at six understood Greek and Hebrew, knew the principles of arithmetic, history, geography, heraldry, and numismatics, and had read the best authors on various branches of literature. Candiac attracted the attention of the learned at Nismes, Montpellier, Grenoble, Lyons, and Paris; and it was for his benefit that the typographic board was contrived by M. Dumas, who superintended his instruction. He died of a complication of disorders, at Paris, in 1726.

CANDIDATE (from *candidatus*, white-robed), a person who aspires to some public office. In the Roman commonwealth, candidates wore a white robe rendered shining by the art of the fuller. This garment, according to Plutarch, they wore without a tunic or waistcoat; either that they might appear more humble, or that they might more easily show to the people the scars of wounds received in battle. See Ambitus.

CANDLE, a cylindrical or slightly conical rod of solid fatty or waxy matters, in the centre of which is a wick formed of cotton fibres which are parallel, twisted, or plaited.

Until of late years, candles were solely manufactured from bees' wax, spermaceti, or tallow. The application of scientific chemical research, however, to this branch of art, coupled with the withdrawal of the vexatious excise supervision, which prevents improvements in every trade which comes under its influence, has so improved the materials used, as well as the manufacture itself, that all the best candles are now made from the pure solid and crystallizable margaric and stearic acids. These are freed from the fluid oleic acid, and from glycerine, which exist in combination with them in ordinary tallow, as well as from other analogous substances, as from paraffine (a carbo-hydrogenous substance resembling spermaceti, prepared from tar and peat), the stearic and margaric acids of the cocoa-nut oil and the palm oil (*Elais guineensis*), besides the old substances spermaceti, and wax both vegetable and animal.

Only the coarsest description of candles are now made from the tallow of the ox or sheep; but as the illuminating power of these candles is small as compared with the improved candles, while their rapidity of combustion is much greater, they are absolutely dearer as articles of consumpt than the candles of improved manufacture. The tallow, cut into small pieces, is melted, when the membranous portions, called the cracklings, rising to the surface, are skimmed off, and freed from their adhering fat by being subjected to pressure. The liquid tallow is then strained through a coarse sieve, and boiling water is mixed with it. The water carries down certain impurities to the bottom of the vessel, and, after settling, the melted tallow is lifted out and is ready for use. In making dip tallow candles the cotton wicks are arranged on sticks on a frame corresponding in size to the dipping cistern, and each frame is suspended from cross-arms which project from an upright beam turning on pivots. The workman turns these arms round, and as each frame comes over the dipping cistern, he presses the frame down so that all the wicks on it are immersed in the tallow. This coats the wick with one thin layer of tallow. The arms are then turned round, and each frame as it successively arrives over the cistern is treated likewise. The layer of tallow added in the dipping becomes consolidated before its turn arrives to receive a second dip, and the arms are turned round, and the candles dipped again and again, until all have acquired the desired thickness and weight, which is known by a counterpoise fixed to the arm.

For ordinary moulded candles, a certain proportion of sheep tallow is melted along with ox tallow, and run into moulds made of pewter finely polished inside. These moulds are not quite cylindrical, but taper slightly towards their point, so as to admit of the more easy removal of the candle. From ten to eighteen of these moulds are fixed by the larger extremity to a kind of trough, their taper points projecting downwards. The wick is then fixed in the centre of the mould, by being drawn through an aperture at the point of the mould which forms the upper end of the candle, and is retained in its place at the open extremity within the trough by means of a wire or other contrivance. The melted tallow being then poured into the trough fills all the moulds, and as soon as it is solidified the redundant tallow is removed from the trough, and the candle drawn out of the mould by means of the end of the wick which has been held by the wire.

The discovery by the celebrated French chemist Chevreul, that fats were composed of three highly inflammable bodies, stearic and margaric acids (solids), and oleic acid (a liquid), combined with a comparatively uninflammable body, glycerine,—has led to the creation of the great new manufacture of stearic and composite candles; the importance and growth of which will be understood when we state, that while in 1833 the new candles were unknown in England, and the quantity manufactured in France amounted to only twenty-five tons *annually*, a single London house (that of E. Price & Co.) manufactured last winter (1854) more than that quantity of stearic and composite candles *daily*, and employs in this business above 900 hands, and a capital of nearly three-quarters of a million.

The old process for making stearic acid may be thus described:—Tallow is boiled up with thin cream of lime, which causes the fat acids by superior affinity to forsake their glycerine and combine with the lime, the glycerine dissolving in the water; this combination is then broken by means of sulphuric acid, which, seizing on the lime, sets free the fat acids; these are then separated (the liquid from the solid), by means of pressure. This process of making fat acids is called "lime saponification." The hard matter remaining in the press is stearic, or a mixture of stearic and margaric acids, and the candles made from it are called stearine, or more properly stearic candles.

In 1840 it was discovered in England that by combining stearic acid with the solid matter, or stearine obtained by pressure from cocoa-nut oil, good candles not requiring snuffing might be made at a considerably less cost than stearic candles. These were called by the inventor "composite." The trade in these composite candles is now immense.

Since 1840 numerous great improvements have been invented, which have resulted in the present manufacture of candles having all the good qualities of the old stearic, while they are sold at prices little exceeding that of tallow candles.

The present improved process is this:—Palm-oil or other fatty matter is exposed at a high temperature to the action of concentrated sulphuric acid, which changes it into a mixture of fat acids of a very dark colour, with a high melting point; this is then distilled in an atmosphere of steam. The distilled material is either used for making the cheaper descriptions of composite candles, or is subjected to hydraulic pres-

sure, first at the temperature of the air, and then at a high heat; the result of pressure being the material used for making what are known as "Belmont sperm," corresponding with stearic candles.

It is a common fallacy to suppose that the capability of a candle to give a good light without requiring snuffing depends more upon its wick than on its material: the same piece of plaited wick which in a stearic candle would give a large good light, would in ordinary tallow give but a feeble glimmer; while a wick suited for common tallow would in stearic material flare away almost like a torch. Arsenic was formerly employed in the manufacture of stearic candles, in order that by its disturbing crystallization it might give a compact uniform appearance to the candle. Happily the modern process of pouring the candle material at so low a temperature into the moulds that crystallization cannot take place, attains the object quite as effectually. The use of arsenic has, therefore, for some time been entirely discontinued.

The mode of making moulded candles by machinery which is employed in the great manufactories, is as follows:—Each frame has a box attached to it, containing a bobbin for each mould; the same movement that expels the one set of candles from the mould uncoils a sufficient length of wick for the next; this is separated from the finished candles by means of a knife travelling on a rack; a set of forceps then holds each wick over the centre of its mould, which is now passed along a railway through a closet heated by steam pipes, by which it is raised to the required temperature by the time it arrives at the filler; having received its charge, it passes on till the material is sufficiently cooled to allow of the forceps being withdrawn without disturbing the position of the wicks. A little further on the superfluous material is scraped off; the mould is then passed across by means of a travelling truck to a parallel line of railway; by the time it has traversed the length of this and arrived at the drawer, the candles are sufficiently cold to be removed. Each machine has on an average 200 moulds, each mould contains 18 bobbins, and each bobbin, when first cottoned, 60 yards of wick.

Wax candles do not appear to have participated in the improvements which have attended the manufacture of the improved stearic or composite candles, and they appear to be still chiefly manufactured by hand. They are made of a cotton or flaxen wick, slightly twisted, and covered with white or yellow wax. Of these there are several kinds; some of a conical figure, used to illuminate churches, and in religious processions, funeral ceremonies, &c.; others of a cylindrical form, used on ordinary occasions. The first are either made with a ladle or the hand. 1. To make wax-candles with the ladle: the wicks being prepared, a dozen of them are tied by the neck, at equal distances, round an iron circle, suspended over a large basin of tinned copper, full of melted wax. A large ladleful of this wax is poured gently on the tops of the wicks one after another, and the operation is continued till the candle arrives at its destined size; with this precaution, that the three first ladles are poured on at the top of the wick, the fourth at the height of three-fourths, the fifth at one-half, and the sixth at one-fourth, in order to give the candle its conical form. Then the candles are taken down, kept warm, and rolled and smoothed upon a walnut-tree table, with a long square instrument of box, smooth at the bottom. 2. As to the manner of making wax-candles by the hand, candle-makers begin to soften the wax by working it several times in hot water contained in a narrow but deep cauldron. A piece of the wax is then taken out, and disposed by little and little around the wick, which is hung on a hook in the wall, by the extremity opposite to the neck; so that they begin with the big end, diminishing still as they descend towards the neck. In other respects the method is nearly the same as in the former case. However, it must be observed that, in the former case, water is always used to moisten the several instruments, to prevent the wax from sticking; and in the latter, oil of olives, or lard, is used for the hands, &c. The cylindrical wax-candles are either made as the former, with a ladle, or they are drawn. Wax-candles drawn are so called because they are actually drawn in the manner of wire, by means of two large rollers of wood, turned by a handle, which turning backwards and forwards several times, pass the wick through melted wax contained in a brass basin, and at the same time through the holes of an instrument like that used for drawing wire fastened at one side of the basin.

Flame has been defined to be a luminous bubble of gaseous matter; it is not, however, necessarily luminous, for the flame of pure hydrogen has but little illuminating power, although its heat is great. If, however, we project into the hydrogen solid matter in a minutely divided state, such as charcoal dust, the solid particles become white hot in passing through the flame, and greatly improve its luminosity. In the flame of candles hydrogen supplies the heat, and minutely divided carbon the light. A candle is a simple but ingenious contrivance for supplying the flame with as much melted material as it can consume without smoking. The fibres of the wick act as a congeries of capillary tubes, which convey the fluid fat into the flame, where, being exposed to a high temperature, and sheltered from the air by the outer shell of flame, it becomes subjected to a dry distillation. The inflammable vapour thus produced rises, and by constant combustion diminishes in quantity, and constantly in diameter, until at length it entirely disappears in a point. We have spoken of flame as a luminous bubble or shell, because it is in fact a hollow body, the exterior only being luminous, where the contact with the air produces perfect combustion. A current of air set in motion by the heat of the flame, causes fresh air constantly to stream up from below; the oxygen of the air, aided by the high temperature, decomposes the inflammable vapour of the fat into hydrogen and carbon; the hydrogen burns, or, in other words, unites with the oxygen of the air, and forms vapour of water; the carbon at the same moment is set free, becomes white hot, and imparts luminosity to the flame; but it does not disappear from the scene of action until it gets to the exterior of the flame, where the oxygen of the air seizes it and forms with it carbonic acid.

The flame of a candle consists of four tolerably distinct portions. 1. The dark interior, containing unburnt combustible vapour. 2. Around this the brilliant part of the flame, or the flame properly so called, where the hydrogen is united with the oxygen of the air, and the carbon, not having yet done so, is in an incandescent state. 3. Beyond this, another film or casing, where the oxygen of the air unites with the carbon. 4. The blue portion at the bottom of the flame, where the inflammable vapour undergoes perfect combustion, and no solid carbon is deposited to afford light. In a well-made candle, the hottest part of the flame is just at the top of the luminous cone where combustion is perfect, and the air not sufficiently in excess to carry away the heat so quickly as at the sides or in the blue part at the bottom.

For a long period tallow candles were subjected to an excise duty of one halfpenny per pound, wax and spermaceti candles to a duty of threepence halfpenny per pound. This was repealed from the 1st of January 1832.

CANDLE, Medicated, the same with BOUGIE.

CANDLES, Rush, are made of the pith of a rush peeled, except on one side, and dipped in grease.

CANDLE, Sale by inch of, an old kind of auction, at which persons were only allowed to bid while a small piece of candle continued burning; the moment it expired the commodity was adjudged to the last bidder.

CANDLE, Excommunication by inch of, is when the f

fender is allowed time to repent while a candle continues burning; after which, he is excommunicated.

CANDLEMAS, a feast of the Romish Church held on the second day of February, in honour of the purification of the Virgin Mary. It is so called from the great number of lights used on that occasion; a custom derived from early Christian times. This feast is supposed to have originated in the declaration of Simeon, that our Saviour was "to be a light to lighten the Gentiles." The Roman Catholics on this day consecrate all the tapers and candles which are to be used in their churches during the whole year. At Rome, the pope performs the ceremony himself, and distributes wax-candles to the cardinals and others, who carry them in procession through the great hall of the pope's palace. This ceremony was prohibited in England by an order of council in 1548.

CANDLEMAS, the second of February, is one of the four terms of the year for paying and receiving rents, interest, &c. In the courts of law Candlemas term begins 15th January and ends 3d February.

CANDLESTICK, an instrument to hold a candle, made in different forms and of different materials.

The candlestick or candelabrum which Moses was commanded to make for the tabernacle was of hammered gold, a talent in weight, and consisted of a base with a shaft rising out of it, of six arms which came out by threes from two opposite sides of the shaft, of seven lamps supported on the summits of the six arms and central shaft; and the arms and shaft were ornamented with "cups, globes (or pomegranates), and blossoms," three cups being allotted to each arm, and four to the shaft. According to Jewish tradition, each arm rose to a level with the summit of the shaft,—which is borne out by the representation of it on the arch of Titus. The extremities of the arms and shaft supported the seven golden lamps, which were filled with oil and cotton.

The seven lamps were lighted every evening, and extinguished every morning. This candelabrum was placed in the holy place, on the south side, and served to illuminate the altar of incense and the table of show-bread. When Solomon built the temple, he placed in it ten golden candelabra, five on the north and five on the south side of the Holy Place; but after the Babylonish captivity, the golden candlestick was again placed in the temple, as it had been before in the tabernacle by Moses. This candelabrum is the one which, after the destruction of Jerusalem, was carried with other spoils to Rome; then, A.D. 455, became a part of the plunder which Genseric transported to Africa; was again, about A.D. 533, recaptured from the Vandals by Belisarius, and carried to Constantinople, and was thence sent to Jerusalem, and from that time disappeared altogether. It is to this candelabrum that the representation on the arch of Titus at Rome was intended to apply; and, although the existence of the figures of eagles and marine monsters on the pediment of that lamp tends to render the accuracy of that copy questionable, yet there is reason to believe that, in other points, it may be relied upon as a reasonably correct representation of the Herodian candelabrum. (See Reland, *De Spoliis Templi Hierosolym., in Arcu Titiano*, ed. sec. Schulze, 1775.)

CANDOLLE, AUGUSTIN PYRAMUS DE, a celebrated botanist, born at Geneva in 1788, was descended from one of the most ancient families of Provence, who had been expatriated for their religion. His father was a famous printer, and syndic of the university and republic. De Candolle began his studies at the college of Geneva, by attending the courses of Saussure and Vaucher, the latter of whom first inspired him with a love of botanical science. In 1795, when Geneva lost her independence, he removed to Paris, where he soon gained the friendship of Jussieu and Desfontaines. His first productions, *Historia Plantarum Succulentarum*, and *Astragalogia*, introduced him to the notice of Cuvier (whose chair in the Collége de France he supplied in 1802), Humboldt, Biot, and Lamarck, who afterwards confided to him the publication of the third edition of the *Flore Française*. Having been elected doctor of medicine by the medical faculty of Paris, he wrote, as an inaugural work, the *Essai sur les propriétés médicinales des Plantes comparées avec leur classification naturelle*; and soon after, in 1806, his *Synopsis plantarum in Flora Gallica descriptarum*. At the desire of the French government he spent a considerable part of the following six years, during which he was professor at Montpellier, in making a botanical and agricultural survey of the whole kingdom; the results of which he published in 1813. From Montpellier he removed to Geneva in 1816, having been invited by the now independent republic to fill the newly created chair of natural history. The rest of his life was spent in an attempt to construct a new system of botanical classification. The results of his labours in this department are to be found in 2 vols. of his *Regni vegetabilis systema naturale*, and in 7 vols. of the *Prodromus systematis regni vegetabilis*. He died in 1842 at Turin, whither he had gone to attend a scientific reunion, having completed only about two-thirds of his proposed task, which has, however, been continued by his son.

CANDY. See KANDY.

CANDY, or *Sugar Candy*, a preparation of sugar made by melting and crystallizing it six or seven times, to render it hard and transparent.

CANDYING, the method of preserving fruits, &c. in substance, by boiling them in sugar.

CANE (Latin *canna*), includes several species of plants belonging to different genera, as Arundo, Calamus, Saccharum, &c. See the articles BAMBOO, BOTANY, SUGAR.

The most beautiful canes are those brought to Europe from the East. These are much used as walking-sticks, and for the handles of umbrellas.

CANE also denotes a measure of length in several parts of Europe: at Naples, 7 feet 3½ inches; at Toulouse, 5 feet 8½ inches; in Provence, &c. 6 feet 5½ inches.

CANE, a river of Hindustan, which has its source on the north side of the Vindhya mountains, in the province of Bundelcund at an elevation of 1700 feet above the sea. N. Lat. 23. 54., E. Long. 80. 13. After a winding course of about 250 miles, it falls into the Jumna on its right bank at Chilatara.

CANEA, or KHANIA, the principal seaport of Candia, is situated on the northern coast, N. Lat. 35. 28. E. Long. 24. 1. Its harbour, formed by a mole nearly 1200 feet long, and protected by a lighthouse and fort, admits of vessels of considerable tonnage. Its entrance, which has a depth of 24 feet, is much exposed to the north wind. It is the seat of a Greek bishop, who is suffragan to the metropolitan at Candia, and contains several Greek churches. The Mussulmans have numerous mosques; the resident Jews are formed into a synagogue. The principal manufacture is soap. Few British vessels touch either at Canea or the other ports of Candia. Pop. 8000, of whom 5000 are reported to be Mohammedans.

CANEPHOROS (*i.e.* basket-bearer), in *Grecian Antiquity*, a maiden whose office it was at the festivals of Minerva, Ceres, and Bacchus, to carry the sacred utensils for sacrifice in a shallow wicker basket on her head. At Athens this office was accounted so honourable, that two virgins of the highest rank were appointed for the purpose.

On an antefixa in the British museum, two canephoræ are represented standing before a candelabrum.

In architecture, *canephoræ* are figures of young persons of either sex in imitation of the above. They are sometimes confounded with *caryatides*.

Canephoræ also denoted those virgins who, when mar-

riageable, presented baskets of offerings to Diana, in order to propitiate that goddess on their renunciation of the virgin state.

CANES VENATICI, in *Astronomy*, the Greyhounds (Asterion and Chara), a constellation first established by Hevelius, between the tail of the Great Bear and Bootes's arms, above the Coma Berenices. It contains 25 stars.

CANGE, CHARLES DU FRESNE, SIEUR DU, one of the most learned writers of his time, was born at Amiens, December 18, 1610. His father, who was royal provost of Beauquesne, sent him at an early age to the Jesuits' College in Amiens, where he soon distinguished himself. Having completed the usual course at this seminary, he applied himself to the study of law at Orléans, and afterwards went to Paris, where he was received as advocate before the parliament in August 1631. Meeting with little success as a barrister, he returned to his native country, where he applied himself to the study of history. After the death of his father, Du Cange married at Amiens, on 19th July 1638, Catherine Du Bois, daughter of a treasurer of France; and, in 1647, he purchased the same office, the duties of which in no degree interfered with the great literary works in which he had engaged. The plague, which in 1668 desolated Amiens, forced him to leave that city. He established himself at Paris, where he was enabled to consult charters, diplomas, titles, manuscripts, and a multitude of printed documents, which were not to be met with elsewhere. He was often aided in his researches by his friend M. d'Héronval. Having in 1688 been seized with strangury, he died of its effects on the 23d October. To the attributes of a good son, a good husband, and a good father, Du Cange united those of extreme gentleness, affability, and modesty. His industry was exemplary and unremitting; and the number of his literary works would be incredible, if the originals, all written in his own hand, were not still extant. In his productions are united the characters of a consummate historian, an exact geographer, a profound jurist, an enlightened genealogist, a learned antiquary, and one deeply versed in the science of medals and inscriptions. He knew most languages, possessed a thorough acquaintance with literature, and from a vast number of manuscripts and original documents drew much curious information respecting the manners and customs of the darkest ages. The learned prefaces of his glossaries afford ample proofs of his philosophical genius, and are, of their kind, models in point both of matter and of style.

Du Cange published the following works:—1. Histoire de l'Empire de Constantinople sous les Empereurs François. Paris, 1657, folio. 2. Traité Historique du Chef de S. Jean-Baptiste. Paris, 1666, 4to. 3. Histoire de S. Louis, Roi de France, écrite par Jean, sire de Joinville. Paris, 1668, folio. 4. Joannis Cinnami Historiarum de rebus gestis a Joanne et Manuele Comnenis, libri vi., Græce et Latine, cum Notis historicis et philologicis. Paris, 1670, folio. 5. Mémoire sur le projet d'un nouveau Recueil des Historiens de France, avec le plan général de ce Recueil, inserted in the *Bibliothèque Historique de la France*, by Père Lelong. 6. Glossarium ad Scriptores mediæ et infimæ Latinitatis. Paris, 1678, 3 vols. fol. 7. Lettre du Sieur N. Conseiller du Roi, à son ami M. Ant. Wion d'Héronval, au sujet des Libelles qui de temps en temps se publient en Flandres contre les RR. PP. Henschenius et Papebroch, Jésuites. Paris, 1682, 4to. 8. Historia Byzantina duplici Commentario illustrata. Paris, 1680, fol. 9. Joannis Zonaræ Annales ab exordio Mundi ad mortem Alexii Comneni, Græce et Latine, cum Notis. Paris, 1686, 2 vols. fol. 10. Glossarium ad Scriptores mediæ et infimæ Græcitatis. Paris, 2 vols. fol. 11. Chronicon Paschale à Mundo condito ad Heraclii Imperatoris annum vigesimum. Paris, 1689, fol. This last work was passing through the press when Du Cange died; and, on his demise, it was edited by Baluze, and published with an éloge of the author prefixed. His manuscript autographs, and his extensive and valuable library, passed to his eldest son, Philippe du Fresne, who died unmarried, four years after. François du Fresne, the second son, and two sisters, then received the succession and sold the library, when the greater part of the manuscripts was purchased by the Abbé du Champs, who handed them over to a bookseller called Mariette, who re-sold part of them to Baron Hohendorf. The remaining part was acquired by D'Hozier, the genealogist. But the French government, sensible of the importance of all the writings of Du Cange, succeeded, after much trouble, in collecting the greater portion of the manuscript autographs of this eminent scholar. Among these manuscripts was one entitled *Gallia*, a work of incredible erudition, being a history of France, divided into seven epochs, with a number of dissertations, the greater part of which are ready for the press, whilst, in regard to those which are not so, abundant materials have been provided for its completion. (J. B—E.)

CANGI, CEANGI, or *Cangani*, ancient inhabitants of Britain, concerning whom antiquaries have been much divided. Camden discovered some traces of them in many different and distant places, as in Somersetshire, Wales, Derbyshire, and Cheshire. Baxter, again, supposed that the Cangi or Ceangi were not a distinct nation, but such of the youth of many different nations as were employed in tending the flocks and herds of their respective tribes. Almost all the ancient nations of Britain had their ceangi, or keepers of their flocks and herds, who ranged over the country in great numbers. This is the reason that vestiges of their name are to be found in so many parts of Britain, but chiefly in those parts which are most fit for pasturage. These ceangi of the different British nations, naturally brave, and rendered still more hardy by their way of life, went armed for the protection of their flocks from wild beasts; and these arms they occasionally employed in the defence of their country.

CANGIAGIO, or CAMBIASI, LUCA, one of the most eminent of the Genoese painters, was born in 1527. He was remarkable for the ease and spirit of his design. His works at Genoa are very numerous; and he was employed by the king of Spain to paint the ceiling of the choir of the Escurial. This great work represents the assemblage of the Blessed. Cangiagio died at the Escurial in 1585.

CANICATTI, a town of Sicily, in the province of Girgenti. It is well built and finely situated on the slope of a hill. The inhabitants principally devote themselves to agricultural pursuits. Pop. 18,000.

CANICULA, a star in the constellation *Canis Major*, called also *Sirius* or the *Dog-star*. It is situated in the mouth of the constellation, and is of the first magnitude, being the largest and brightest of all the fixed stars. From the rising of this star heliacally, that is, its emersion from the sun's rays, the ancients reckoned their *dies caniculares*, or dog-days. The Egyptians and Ethiopians began their year at the rising of the canicula, reckoning to its rise again the next year, which is called *annus canarius*, or canicular year. This year consisted ordinarily of 365 days, and every fourth year of 366, by which it was accommodated to the civil year. The reason of their choice of the canicula to compute time by was, not only the superior brightness of that star, but because its heliacal rising was in Egypt a time of singular note, as falling on the greatest augmentation of the Nile, the reputed father of Egypt. Hephæstion adds, that from the aspect and colour of the canicula the Egyptians drew prognostics concerning the rise of the Nile; and according to Florus, they predicted the future state of the year; so that the first rising of this star was annually observed with great attention.

CANICULUM, or CANICULUS, in Byzantine antiquity, a golden standish in which was kept the sacred *encaustum* or red ink with which the emperors signed their decrees, letters, &c. It probably derived its name from being supported by the figures of dogs.

CANINE MADNESS. See VETERINARY SCIENCE.

CANINI, GIOVANNI AGNOLO, a designer and engraver, born at Rome in 1617. He was a pupil of Domenichino, and afterwards of Barbalunga. He painted some good altar pieces at Rome, including two fine pictures for the church of St Martino a Monti, representing the Martyrdom of St Stephen and of St Bartholomew. Having accompanied Car-

dinal Chigi to France, he was encouraged by the minister Colbert to carry into execution his project of designing from medals, antique gems, and similar sources, a series of portraits of the most illustrious characters of antiquity, accompanied with memoirs; but shortly after the commencement of the undertaking, Canini died at Rome, in his 48th year. The work, however, was prosecuted by his brother Marcantonio, who, with the assistance of Picard and Valet, completed and published it in 1699, under the title of *Iconografia di Gio. Ag. Canini.* The engravings amount to 150, and a curious explanation is given, which attests the learning and taste of the brothers Canini. A reprint of this work in Italian and French appeared at Amsterdam in 1731.

CANIS, or Dog. See Mammalia.

Canis *Major*, the Great Dog, a constellation of the southern hemisphere, below Orion's feet.

Canis *Minor*, the Little Dog, a constellation of the northern hemisphere; called also by the Greeks *Procyon*, and by the Latins *Antecanis* and *Canicula*.

CANISIUS, or de Hondt, Henry, a native of Nimeguen, and one of the most learned men of his time, was professor of canon law at Ingolstadt. His principal works are, *Summa Juris Canonici* and *Antiquæ Lectiones*. This latter very valuable work was reprinted, with some curious and useful remarks, under the title of *Thesaurus Monumentorum Ecclesiasticorum et Historicorum*, &c., Amsterdam, 1725, in seven parts, usually bound in 4 vols. folio. Canisius died in 1610.

CANITZ, Friedrich Rudolph Ludwig, *Baron of*, a German poet and statesman, and privy-counsellor of state, was descended of an ancient and illustrious family in Brandenburg, and born at Berlin in 1654. After studying at Leyden he travelled in France, Italy, Holland, and England; and, upon his return to Germany, was charged with important negotiations by the Second and Third Frederics. His German poems were published for the tenth time in 1750, in 8vo. He is said to have taken Horace for his model, and to have written purely and delicately. He not only cultivated the fine arts himself, but gave all the encouragement he could to others to do so likewise. He died at Berlin in 1699.

CANKER, a disease incident to trees, which causes the bark to rot and fall.

CANNÆ, in *Ancient Geography*, a town of Apulia, near the Adriatic, on the right bank of the river Aufidus, 6 miles from its mouth. It is famous for a terrible overthrow which the Romans here received from the Carthaginians under Hannibal. See Rome. A great diversity of opinion has always prevailed as to the exact spot on which the battle was fought. The majority of modern historians and topographers, however, now agree in referring it to the south side of the river; but Swinburne, one of the best authorities on the subject, concluded from personal observation and a careful comparison of authorities that the scene of conflict lay on the northern bank; and in this opinion he is supported by Niebuhr. The modern village of Canne, 8 miles W.S.W. of Barletta, now occupies the site of this interesting town.

CANNEL Coal. See Mineralogy.

CANNES, a seaport-town of France, capital of a canton in the department of Var, on the Mediterranean, 25 miles east of Draguignan. It occupies the declivity of a hill projecting into the sea, and has an old Gothic castle, and a fine quay. The harbour, however, is accessible only to small coasting vessels. The country around is fruitful in oranges, olives, citrons, grapes, and other fruits, which, with the production of its fisheries, constitute its exports. Napoleon landed here after his escape from Elba, 1st March 1815. Lord Brougham has a seat in the neighbourhood.

CANNIBAL (probably a corruption of the word *Carib*), an anthropophagite or human being that eats human flesh. A tribe of this name inhabited a part of the Antilles before the arrival of the Spaniards, who destroyed nearly the entire race. In the island of St Vincent, where their numbers were originally very large, their descendants are still to be found greatly reduced in power, and considerably modified in character. They are, in general, downcast and given up to idleness and day-dreams. They have dark-olive complexions, and flat brows and nostrils. They are well-made, however, and possess great strength and powers of endurance. When roused from their usual apathy, they make excellent warriors, and are peculiarly formidable from their skill in archery. Their arrows are made in such a manner, that they cannot be extracted from the body against which they have been aimed without tearing the wound, and are, besides, dipped in the deadly juice of the manchineel. Polygamy is universal among them. As they have always been represented as in the habit of roasting and eating the flesh of their prisoners, their name has passed into a proverb in all languages. It is not altogether established whether they indulged in this horrid practice from the difficulty of obtaining more legitimate means of subsistence, or from a cruel desire to take the most complete vengeance over their enemies. The Caribs, however, were far from being the only savages among whom the custom prevailed. Among certain tribes of North American Indians, the flesh of conquered enemies was consumed on principle; and the greatest luxury which a successful warrior could enjoy, was the heart of some brave chief whom he had slain in battle. Considerable diversities of taste, however, prevailed among the savages in different parts of the world, as to the most delicate portions of the human frame. Among the South Sea Islanders, the palm of the hand, especially of a young girl, was long looked upon as the most dainty morsel; while the New Zealanders gave a decided preference to the foot. The epicures among the Feejee Islanders were said to regard with great aversion the flesh of the civilized white man; and instances are on record in which they are reported to have spared the crews of English and French ships wrecked on their coasts, as they had found by experience that the flesh of such persons was tainted to an unpalatable extent by the savour of salt and tobacco.

CANNING, George, a celebrated statesman and orator, was born in London on the 11th of April 1770. His father by an imprudent marriage had drawn down upon himself the displeasure of his parents, and was by them cut off with the scanty pittance of L.150 per annum. The youth, thus discarded by his family, who possessed considerable property in Ireland, left that country, and repaired with his wife to London. His efforts to extend the means of their subsistence were, however, unavailing; and exactly twelve months after the birth of his son he died, the victim, it is said, of a broken heart. The mother of Canning, thus left comparatively destitute, attempted the stage, but without success. Of her after history little is known, except that she was twice married, and to the day of her death experienced the tender regards of her illustrious son, whose success she lived long enough to witness.

The education of Canning, however, was not neglected. By the liberality of an uncle he was placed at Eton, where he greatly distinguished himself, not only in his scholastic exercises, but also as a literary aspirant. At the age of sixteen we find him editor of a periodical miscellany entitled the *Microcosm*, which was got up amongst his school associates. To this work he contributed a variety of papers, distinguished for their elegance and taste, and also for a playful humour, which afterwards became so formidable a weapon in his hands. To this period likewise is assigned the composition of a poem entitled *The Slavery of Greece*, which displays a glowing fancy, and a rare maturity of thought, whilst it breathes the warmest sentiments of freedom. This was a happy presage. For he

afterwards rose to a situation which enabled him to mitigate the destiny he thus early and feelingly deplored; and it is pleasing to add, that the fervour of the youthful bard was never altogether quenched in the after calculations of the statesman. In the year 1787 he left Eton for Christ Church, Oxford, where he rapidly rose to distinction. He gained several prizes for his Latin essays, and attracted considerable notice by his orations. The general impression of his compeers appears to have been, that he was destined to excel, and would rise to the head of whatever profession he chose to adopt. Amongst his fellow collegians was the Honourable Charles Jenkinson, with whom he contracted an intimacy which was afterwards of great advantage to him. It became necessary for him, however, to think of a profession, and he fixed upon the law as that most likely to afford scope for his talents. He accordingly quitted Oxford for Lincoln's Inn, whither his fame had preceded him. It may be doubted whether he was as laborious a student of law as he had been of learning. His disposition was highly sociable, and his wit was the theme of general admiration. Hence his society became courted by a numerous and rapidly extending circle of friends; and he also began to attend debating clubs, where he frequently spoke. These trials of skill gave him confidence as a public speaker, and tact and acuteness as a debater, whilst at the same time they exercised his powers of elocution; thus preparing him for contending with more powerful and expert antagonists in a more exalted arena. At this period his principles were liberal. He had long been in familiar intercourse with Sheridan, by whom he was introduced to Fox, Burke, Grey, and the other leading Whigs of the time, who looked upon him as the future champion of their cause, and advised him to turn his thoughts from the bar to the senate; and this he accordingly determined upon. But a change soon came over the spirit of his politics. What motives induced him to abandon the creed in which he had hitherto believed, it is difficult to conjecture. Probably he felt that even genius like his would not rise to the full growth of its ambition on the opposition benches, or that the interests of his country would be better served if he could infuse into the measures of his new associates a portion of that liberality which distinguished those of his old. But whatever may have determined the choice of the young politician, certain it is, that after a friendly and candid explanation to Sheridan, he entered into terms with Pitt, and in 1793 took his seat in parliament under the auspices of that minister. But it was not until 1794 that he ventured to address the house. The occasion was by no means auspicious; it was in support of a large subsidy to the king of Sardinia for prosecuting the war. He was brought into immediate collision with Fox, whom he ventured to treat with a considerable degree of levity; and it did not reflect much credit on Pitt, that he thus subjected his great and generous rival to the flippant attack of a man so young and so arrogant as Canning. Apart from this circumstance, the speech displayed considerable tact and dexterity in the management of an argument. From this period his support of the premier was close and undeviating, and he gradually rose to distinction amongst the party to which he had allied himself. In 1796 he was appointed one of the under secretaries of state, and for the first two years during which he held the situation he principally confined himself to the laborious duties connected with it. In 1798 he recorded his sentiments on the subject of the slave-trade, being favourable to abolition; and in the same year he electrified the house on a motion of Mr Tierney's respecting a peace with the French republic. It was a speech of masterly skill and eloquence, and fully justified the presage of his youth and the partiality of his master. The same year his consequence was materially increased by his union with Miss Joan Scott, one of the daughters and co-heiresses of General Scott. Miss Scott's two sisters were married to noblemen; and Canning's parliamentary interests were thus not only powerfully strengthened, but he was furnished with a respectable independence.

In 1800 we find him discussing in parliament the overtures of peace made by the consular government of France, the habeas corpus suspension bill, subsidies to the Emperor of Germany, and the state of the nation,—subjects on all of which he supported the minister, and in regard to some of which he displayed more devotedness as a partizan than wisdom as a statesman. Out of doors also he employed the formidable weapon of the press in the same warfare. In conjunction with his friends Mr Frere and Mr Ellis, he brought out the *Antijacobin Examiner*, a weekly paper, alike distinguished for its wit and talent and for its satire and ribaldry. The poetical compositions of Canning formed the attic salt of this print; and, keeping out of view their malignant invective and personality, they are unquestionably full of wit.

The resignation of Pitt in 1801 deprived Canning of his situation; and the ministry which succeeded he took every opportunity of strenuously opposing. The return of the former to power in 1804 again restored him to office as treasurer of the navy. From this period till the death of Pitt nothing remarkable occurred to call forth his energies, except the impeachment of Lord Melville, whose cause he warmly espoused. By the demise in 1806 of his illustrious preceptor in politics, Canning was again removed from office; and during the reign of the ministry which succeeded, he conducted himself in the same manner as he had done upon a like occasion before; strenuously opposing all measures except those which he considered as sanctified by the authority of Pitt. Nothing can more forcibly exhibit the influence of party spirit over his mind, than the manner in which he allowed the question of the abolition of the slave-trade to be carried in parliament. Under other administrations it had received his powerful advocacy, and all the resources of his genius were arrayed on the side of humanity; but now he scarcely lifted his voice upon the occasion. What he did say was cold and petulant. On a great moral question touching the rights of human nature he could not subdue expressions of hostility to the existing ministry. The latter having abandoned office, the Tory party came again into power, and Canning received the seals of the foreign department.

The office of a minister of foreign affairs at the commencement of the Portland administration was any thing but an enviable post. With the exception of the short interval of the peace of Amiens, England had been engaged in a war of fifteen years' duration. Most of the continental powers, formerly her allies, were now either leagued against her, or condemned to an inglorious neutrality. The nation, which previously divided its belief between the two great leaders now no more, looked in vain for one sufficiently prominent to command its confidence. The mantle of either prophet appeared to have ascended along with him; for as yet Canning had not gathered all his fame, and was looked upon by the country as a light and harassing skirmisher rather than a heavy man-at-arms. The administration just dissolved presented a formidable opposition; and a number of the members of it, indeed, Canning had made personal enemies of by his caustic raillery in parliament, and his reckless satire out of doors. In circumstances of such difficulty the new ministry found themselves placed. It was on Mr Ponsonby's motion relative to the expedition to Copenhagen that their strength was first properly put to trial. This attack could not be

justified on any principle of justice. Canning, however, fearlessly threw himself into the arena, and delivered a defence of the conduct of ministers, at least remarkable for its ability and eloquence. Both friends and opponents regarded him with admiration. The former saw the value of the acquisition they had made, and the latter the formidable talent with which they had to contend. From this period Canning continued to rise in importance and increase in fame. He was the most able and strenuous supporter of the administration to which he belonged. In 1809 a political misunderstanding with Lord Castlereagh led to a duel, in which Canning was wounded. Both secretaries resigned, and the consequence was a dissolution of the ministry.

During the two years which followed this event, Canning seldom appeared in the stormy arena of debate. Two speeches, however, on the resumption of cash payments by the bank of England, belong to this period, but are numbered amongst his least successful exertions. In the beginning of 1812 he advocated the claims of the Catholics to civil power, which he invariably supported, not as an abstract question of right, but as a matter of expediency. On the assassination of Mr Percival, overtures were made to him to accept a place in the cabinet; but his favourite measure of Catholic emancipation forming no part of their arrangements, he declined taking office. In this year he was chosen as representative for Liverpool, which also returned him to other three successive parliaments. In 1814 he accepted the situation of ambassador to Lisbon, and continued there till 1816, when he returned, and soon afterwards joined the ministry as president of the board of control. During the last two years great events had taken place, in bringing about which Canning had no inconsiderable share. "If there was any part of his political life," he declared on one occasion, "in which he gloried, it was, that in the face of every difficulty, discouragement, and prophecy of failure, his had been the hand which had committed England in an alliance with Spain." "Never," said he on another occasion, "ought we to relinquish our hold of the Peninsula. The ruler of France has one grand object to which he stands pledged—the establishment of his dominion there. If he fail in this, his defeat will be most signal." The result realized his prediction. By British policy and valour, which he animated and encouraged, the tide of military despotism which had overflowed the Continent was repelled beyond the Pyrenees, and the ancient landmarks of nations re-appeared above the subsiding wave.

As a member of the cabinet from 1816 till 1820, Canning was a strenuous supporter of its measures. The celebrated six acts called forth all the resources of his eloquence to prove their necessity, and to lessen the abhorrence with which a large proportion of the community contemplated them. The manner in which he treated the case of one Ogden, who was incarcerated for sedition under the suspension of the habeas corpus act, was aggravated by opponents into a serious crime, and in any view evinced a reckless and unfeeling levity, which it is easy to palliate but impossible to justify.

On the demise of George III. in 1820, parliament was dissolved, and Canning, at the next election, was for the fourth time returned for Liverpool. On this occasion he put forth all his strength in vindication of the proceedings of ministers. During his speech he also took an opportunity of expressing his unmeasured hostility to all parliamentary reform, which he afterwards reiterated in parliament in 1822, in one of his most finished orations. On the return of Queen Caroline to share the throne of her husband, Canning, who had formerly been on terms of great intimacy with her, felt constrained to absent himself from England during the progress of the proceedings which were instituted against her. On his return from the Continent he resigned the presidency of the board of control, and on his retirement received the most flattering testimony from the Court of Directors of the East India Company, of the value which they attached to his services. The golden opinions which the members of that influential body entertained of his character, and the universal conviction that no man was better qualified or entitled to occupy the highest official situation which they had it in their power to bestow, induced them ultimately to confer upon him the appointment of governor-general of India. But just as he was preparing to quit England, the Marquis of Londonderry died; and a vacancy having thus been created in the cabinet, Canning was invited by his sovereign to resume the situation of secretary for foreign affairs. He accepted the offer, and though second in office, in public opinion and in real efficiency he was considered as the first. This took place in 1822.

During the remainder of Canning's life his history becomes so closely interwoven with that of his country, that a minute detail is unnecessary. He infused into the counsels of the cabinet a degree of liberality which, for a long period, had not characterized them. The spell of the holy alliance it was his studious endeavour to break; and without altogether alienating the continental powers from Britain, he aimed at placing her in a situation where, untrammelled, she might exercise her own free will. It was his desire that his country should occupy a neutral station, and assume the character of mediator, not only between conflicting kingdoms, but between the hostile factions of individual nations. He strongly countenanced, both in theory and practice, that amelioration in regard to commerce, navigation, and manufactures, which the force of circumstances and the progress of information had rendered imperative. In June 1824 the cabinet determined on recognizing the independence of Mexico, Colombia, and Buenos Ayres. This measure was principally brought about by the exertions of Canning, and in one of his speeches he claims the merit of it. In answer to the argument that ministers had sanctioned the attack on Portugal, by having permitted the occupation of Spain by France, he said, "Was it necessary that we should blockade Cadiz? No. I looked another way. I resolved that if France had Spain, it should not be Spain with the Indies. I called the new world into existence to redress the balance of the old." In the autumn of 1826 he went to Paris, and was received with great distinction. The treaty with France and Russia respecting Greece, and the events at Navarino which followed closely after it, throw light upon the object and intent of his visit. His highest powers were also called forth on the occasion of the aggression of Spain upon Portugal. He warmly maintained the necessity of England's interference upon the occasion; and the demonstrations which were made produced the desired results. These are the three measures on which the fame of Canning, for liberal policy, principally rests.

In the beginning of 1827, at the funeral of the Duke of York, he caught a severe cold, from the effects of which he never altogether recovered. Shortly after this the Earl of Liverpool, then prime minister, was seized with paralysis; and though he rallied afterwards, he was politically dead from the moment he was struck. Canning was ultimately appointed first lord of the treasury. Considerable opposition followed this appointment, and six members of the former cabinet resigned. The new premier, however, struggled manfully against this rather unexpected opposition, and with great celerity completed the com-

Cannon.

plement of the cabinet. But the harassing contest which he had to maintain against a virulent opposition visibly affected his health. Towards the latter end of July 1827 he was invited to the seat of the Duke of Devonshire at Chiswick, in hopes that the change of air might renovate his constitution; and he did recover so far as to be able again to transact business in Downing Street; but his malady, which was an inflammation of the kidneys, returned, and he expired on the 8th of August, at the age of fifty-seven. His remains were interred in Westminster Abbey, near to those of his great preceptor Pitt, on the 16th of the same month. The funeral, though private, was attended by the Duke of Clarence, afterwards William IV., a number of the nobility, and other friends.

The death of Canning was a circumstance rarely paralleled in interest amongst civilized nations. In his foreign policy he had identified himself with the march of independence. From Lima to Athens the effects of his friendly interposition had been felt, and a sorrow corresponding to the benefits he had conferred was expressed when he fell. He was cut off in the midst of designs of high enterprise, and before all his plans were completed; and thus his system, and much of his fame, was left at the mercy of his successors. The great events which have taken place since his death have also tended in some measure to eclipse his popularity. His accomplishments as an orator were of the highest order. His form was commanding, and his features handsome and impressive. His voice was richly toned and highly musical, and his attitudes were elegant and striking. His delivery was manly, and for the most part he was in complete possession of himself. These qualities and accomplishments set off to double advantage the more exalted gifts of intellect with which he was so richly endowed. His diction was splendid, his reasoning acute and refined. He exercised a sovereign command over language, and it flowed from him with classic elegance and ease. His style, strictly speaking, was not ornate. Wit was an ingredient with which he frequently seasoned his oratory, thereby imparting to it a high relish. The vein was peculiarly his own; it was lively and playful, and calculated more to ridicule than to lacerate. His poetical powers may be ranked among his elegant accomplishments; and, for the most part, the productions which resulted from them are the least worthy of his fame—not that they want the requisite talent, but that they are in general disfigured by scurrility and invective. "He was," says Sir James Mackintosh, "a man of fine and brilliant genius, of warm affections, of high and generous spirit; a statesman who at home converted most of his opponents into warm supporters, who abroad was the sole hope and trust of all who sought an orderly and legal liberty, and who was cut off in the midst of vigorous and splendid measures, which, if executed by himself, or with his own spirit, promised to place his name in the first class of rulers, among the founders of lasting peace, and the guardians of human improvement." (J. F. S.)

CANNON, a generic term under which may be arranged all pieces of ordnance which from their weight or form cannot be used as the personal weapon of the soldier, such as guns, carronades, howitzers, and mortars. A brief historical sketch of the substitution of these tubular propelling machines for the mechanical instruments of war which had been used before the invention, or at least the practical application of gunpowder as a propulsive agent, has been given under the article Artillery; and such additional particulars will be here cited from the excellent Spanish treatise on artillery by Don Claudio del Fraxuo and Don Joaquin de Bouligny, as are necessary to explain satisfactorily the progressive improvements in the manufacture of cannon. In applying the suddenly developed impulsive force of ignited gunpowder to the propulsion of heavy projectiles, it is necessary to inquire what should be the properties of the material to be used in the manufacture of the tube, cylinder, or cannon, in which the powder is intended to be ignited, and from which the projectile is to be propelled. Such material then should possess hardness sufficient to resist the shock of the projectiles; should be capable of resisting the chemical action of the air, or of the compounds generated by the combustion of gunpowder, and augmented in their destructive agency by the heat produced by ignition; should possess sufficient elasticity to resist a disruption of continuity, or a permanent change of condition, resulting from the vibrations produced, either in rapid transport or by frequent discharges; and also a tenacity sufficient to resist the enormous pressure exercised by the elastic gases at the first moment of their development, which has been estimated by Preehll so high as 18,000 atmospheres, and by Hutton as 20,000, or even in the latter case at about 15,000 lb. per square inch of the bore of the tube or cannon. A deficiency in any one of these properties must lead to the rapid deterioration of the cannon: as want of hardness to the indentation, scratching, and grooving of the bore; want of elasticity to a change in its form and a diminution of its strength after every discharge; want of tenacity to a partial separation of its parts under pressure, and, finally, to decided fracture. It often happens that guns which have withstood the severe trial of proof charges, and have been subjected afterwards to much firing, suddenly burst under the effects of a very moderate charge; a result which must be attributed to a deficiency in one or more of these important properties, and which renders very doubtful the propriety of subjecting guns to excessive proof, by which they are often, though imperceptibly, much deteriorated.

The only simple substance in which the properties of hardness, elasticity, and tenacity are sufficiently blended together to produce an efficient result (for it must be observed, that to a certain extent they are opposed to each other), is iron; excluding, of course, from that term cast-iron, as being a compound or carburet. Various attempts, therefore, have been made from a very early epoch, to manufacture guns of wrought or forged iron, and only a few months have passed since a gun of this description, invented by Captain Simmons, Royal Engineers, was submitted to trial by the artillery authorities. There can be little doubt, indeed, that excellent guns might be manufactured from forged iron, and should it be found possible hereafter, either by rifling the bore of guns, or by altering the form of the shot, to diminish the charge of powder, as in the Minie and similar rifles, it is by no means improbable that forged iron will again be adopted as a material for field guns. The difficulty of completely purifying iron from the sulphur and phosphorus usually associated with it, and which render it brittle, naturally led to many failures in the early days of artillery; and it was thus that James II. of Scotland perished before the walls of Roxburgh in 1460, from the bursting of a bombard formed of large iron bars, strengthened and bound together by iron hoops. Notwithstanding these defects, all the guns of the fifteenth century were manufactured in this manner; and the system of forging was so improved, that guns were even made of a single piece, in spite of the great labour and difficulty of managing such heavy masses in the frequent heatings to which it was necessary to subject them in forging. The manufacture of forged cannons was again revived after having been long abandoned; and in 1753, a gun weighing 1600 pounds was forged in Paris, and six years afterwards several guns of various calibres were forged in Spain. In 1813, the St Etienne Iron Company of Lyons proposed to the French government to supply guns of forged iron from their establishment at the rate of eight 24-pounders each day, and forwarded as a specimen an 8-pounder. This

gun was proved by four discharges, with 3 lb. of powder, 1 ball, and two wads, one above the powder and the other above the ball; and then by five discharges with 4 lb. of powder under the same circumstances: the recoil being 24 feet in the first four, and 35 in the last five discharges. The extreme lightness of such guns—a 16-pounder French, about equal to our 18-pounder, weighing about 1650 lb., and a 24-pounder French, equal to a 27-pounder English, about 2100 lb. only—would have rendered the recoil with ordinary charges so excessive, and the destructive effect on the carriage so great, that they could not have been satisfactorily employed in the field; still, however, it should be always remembered, that iron has great advantages over all other simple metals for the manufacture of guns, that it is quite possible to forge good pieces of artillery of iron at two-thirds the cost of bronze, and that it is desirable in the field to obtain as large a calibre for the discharge of spherical and other case shot as is consistent with a reasonable weight, which, perhaps, will hereafter be effected more readily by forged iron than in any other way. Where a long range, and in consequence a powerful charge of powder, are indispensable, this form of gun can scarcely, under existing circumstances, be adopted; or, at least, until some means of diminishing the shock and the recoil, by the intervention of springs, has been discovered; and even then it will be necessary to move the same weight, taking the gun and carriage together, though distributed in a different way.

Cannon of cast-iron.

The precise date of the first cast-iron guns is not known, but it has been asserted by General Haguenin, that a piece of this description at Bois-le-Duc bears the date 1411. Some doubt, however, has been expressed on this subject; and it has been thought more probable, with reference to the invention of high smelting furnaces, to suppose this date 1511. In 1540 Ralph Page cast eight iron guns at Rackstadt; and in 1547 the use of such artillery began to become general, and was for nearly a century exclusively adopted in some countries. In France cast-iron guns were not manufactured before 1600; but so evident were the advantages to be gained by their use, both as regards the qualities of the guns and their moderate cost, that they were speedily adopted in most countries; foundries for iron guns having been established in Silesia in 1470, in Germany in 1577, in Saxony in 1594, in the Hartz in 1626, and in Sweden in 1640; one foundry alone, in the latter country, having been said to have supplied for some time from 400 to 500 cannons annually.

Hollow casting.

All these pieces of ordnance were cast hollow until 1729, when a horizontal boring machine was established at Lyons, and, after some trials made in 1734, M. Maritz abandoned hollow casting at Strasburg in 1744–45, and adopted the boring machines.

Solid casting.

Maritz, who was appointed, in 1755, inspector-general of the foundries of France, did much to perfect the art of solid casting and boring; but, in attempting to obtain a metal which should be easily turned and bored, he led to many failures in the proof, in consequence of which his system was combated by the celebrated Montalembert, and, subsequently, in 1764, the department of the Marine undertook the manufacture of its own cannons. These imperfect trials led to the resumption, for a time, of hollow casting; but an examination of specimens of ancient guns has shewn that the real defect was in the very imperfect casting of early times, fragments of metal unreduced being sometimes found imbedded, as it were, in a paste, very much like the condition of crystals in porphyry.

Reverberatory furnace, and casting in sand.

In 1770 Wilkinson established at Indret a reverberatory furnace, and introduced moulding in sand, as explained by Monge some years afterwards; and in 1780 reverberatory furnaces were applied to the re-smelting of iron for cannons in France, Silesia, Germany, and the Low Countries. In Sweden the use of reverberatory furnaces did not gain ground, as the excellence of its ores rendered them less necessary than in other countries. The efficiency of cast-iron guns was amply tested and proved in the siege of Ciudad Rodrigo in 1812, in the subsequent siege of Badajoz, and in that of St Sebastian in 1813; as the guns used were not deteriorated by the hard work of either of these memorable sieges. At that of Badajoz more than 36,000 projectiles were discharged, and each 24-pounder contributed to that total about 1250 rounds; but, notwithstanding this general success, many examples might be cited of guns bursting in action, which at least point to the necessity of still further improvement, and, it may be added, of a reconsideration of the system of proof.

Necessity of purity.

Whilst the properties of pure iron are so eminently suited to the manufacture of guns, it is necessary to guard against the presence of any of those minerals which in nature are so often associated with it, and which are removed only with great difficulty, as their presence even in small quantities deteriorates the metal. Sulphur, in the proportion of $\frac{1}{20}$th per cent., renders it friable and brittle when hot, and tends to produce white metal. Phosphorus, in the proportion of $\frac{7}{20}$ths per cent., renders it soft and easily worked when hot, but brittle when cold. Antimony renders it brittle when hot, and friable when cold; as does arsenic if in considerable quantity. Manganese augments the hardness of iron without affecting its tenacity, but it prevents the formation of gray metal. Silicon, even in the proportion of $\frac{37}{100}$ths per cent., renders iron brittle. Of other metals, tin in the proportion of 1 per cent., gives iron a fine grain and increased hardness, and renders it more sonorous, but at the same time more brittle when cold. Copper, increasing the hardness and tenacity of iron but in the proportion of $\frac{1}{4}$th per cent., renders it brittle when hot. Titanium renders the ores refractory, but gives to the metal tenacity and hardness. Zinc, chrome, gold, bismuth, and cobalt, in small quantities, do not affect the quality of iron. Nickel renders it fusible, soft, and tenacious. Silver and platinum in small quantity give it hardness and tenacity, and the presence of aluminum causes it to lose the latter property. From a consideration of these results, it is manifest that little can be expected in such a manufacture as that of cannon from any system of alloying iron, and that the main object is to ensure its absolute purity.

Swedish ores.

In Sweden the magnetic iron ores are abundant, forming extensive masses in the granite rocks. They are a mixture of the protoxide and peroxide of iron, in the proportion of 31 protoxide to 69 of peroxide. All these magnetic ores are not equally suited for this purpose, and those are preferred which are highly crystalline in structure. The Swedish iron enjoys a well-merited reputation; and the Swedish foundries of Finspong, Aker, and Stassjo, have supplied artillery not only to Sweden, but to Norway, Denmark, Russia, Piedmont, Naples, and Egypt. The metal for the casting of cannon is obtained both in Sweden and Norway directly from the ore, which is smelted with wood in high furnaces, composed of two truncated cones joined at their bases, the lower and shorter being inverted, and connected with the chamber or crucible which receives the melted metal. The height of these furnaces varies from 30 to about 43 feet, according to the fuel made use of, and about 13 feet of the upper cone form the air or draught chamber.

Rules for selecting a fitting metal.

Mr Moritz Meyer has given the following rules for selecting the metal for casting cannons. The metal which produces the best cannons is that which, cooled in small pieces, is of a clear gray colour, is very finely granular, and exhibits on the surface distant small white facettes like crystals, with a metallic lustre, whilst the general surface is of a greasy lustre. Poured into an empty mould, the surface remains concave with sharp edges, and without hollows or air-bubbles. Cooled in large masses as for cannon, it assumes on the surface a well-defined clear gray colour, and produces an iron of an interwoven texture. The principal mass presents a fine

Cannon.

white grain, and contains small separated groups of graphite-like stars, which in very good iron should not be much less nor greater than pin heads; and in less number they are uniformly disseminated over the whole mass, though in fracture these stars appear more numerous and larger towards the edges. These groups assume sometimes an ellipsoid figure, crystallized like hematite. The rays of these stars should be so small as scarcely to be discernible by the eye alone; for when larger and more visible, or as it were like lamellæ, the iron will be much weaker. The white metal appears to envelope these black groups, and whilst the former is attacked only with difficulty by the file, the latter are rapidly worn away. The recent fracture feels very harsh, and catches the fingers as if bristled with hooks. When turned in a machine, the surface seems as if marked by lines of cleavage, and the graphite groups appear of a stronger tint and more deeply incrusted.

Much difference of opinion has existed respecting the comparative merits of a clear gray, and of a dark or dull gray metal; and doubts have been expressed as to the rules or principles of Mr Meyer; but this at least is evident, that the condition of the metal in respect to the distribution of the plumbago is very peculiar, and that the greatest care must be necessary to insure satisfactory results in casting cannon, more especially those of large size.

In this country, in France, Germany, and the Lower Countries, from the difference of ore used, the first metal obtained in the smelting furnaces cannot, as in Sweden, be cast at once in cannons, but must be again melted in reverberatory furnaces, by which process the extraneous bodies still combined with the iron are removed, and the excess of carbon driven off as carbonic acid—the success of this process depending on the quantity of air admitted to the surface, and the manner in which the flame is directed over the metallic bath. This second reduction of the metal, though adding to the expense, has its advantages, as it enables the founder to mix together the products of different smeltings, and thus to correct the defects of some of them, and to use up the fragments of old guns, and generally to obtain with greater certainty a good metal.

The results of analyses of cast-iron by Gay-Lussac are as follows:—

Gray metal obtained with Charcoal.

From	Carbon.	Silicium.	Phosphorus.	Manganese.	Iron.	Total.

The general result being, that the metal is a mixture of a carbide (carburet), in which one atom of carbon is combined with four of iron, and of a silicide of similar constitution, or quadribasic. It had long been a received opinion that the iron guns of France were inferior to those of both Sweden and England, but Soult, when minister of war in 1832, sent two artillery officers into Sweden to study the manufacture there, and admirals Rigni and Dupperré, on the part of the marine, sent officers also both to Sweden and England. At Aker and Finspong in Sweden, and at Carron these officers had guns cast of three several calibres, viz., 8-pounders, 18-pounders, and 30-pounders, which were subsequently submitted to proof in France, when it is asserted that the Carron guns stood in order of resistance the fourth or last, the French the second, and one or other of the Swedish guns in every trial the first. Whatever may be thought of these reported results, the example of the French may well be imitated by us so far as regards the personal examination by well-instructed artillery officers, not only of foreign cannon foundries but also of our own; and it would be very desirable to have specimens of guns corresponding to our own authorized calibres cast at the most celebrated foreign foundries, such as those of Sweden already named, and that of Liege, to be used in comparison with our guns. In the furnaces of Liege the hot-blast has been adopted.

Proof.

The proofs to which iron guns are subjected before they are received as fit for service vary in different countries. In some each piece is proved by itself, in others only one is proved out of each distinct lot supplied by the founder In France and Belgium iron guns are proved one by one, each gun being fastened to a strong stage or platform of wood, fixed firmly in an ordinary battery so as to prevent recoil, and in this condition making two discharges with a load of powder equal to one-half the weight of the projectile, two balls, and two wads, or one to each ball. In Sweden from three to ten discharges are made from each gun, with charges of powder varying from $\frac{5}{12}$ths to $\frac{8}{12}$ths of the weight of the projectile, and a quantity of balls, after which the guns are carefully examined to ascertain the extent, if any, of deterioration; and should one gun explode still more attention is bestowed on the examination of the others. At the beginning of this century General Hellwig proposed a system of proof varying in strength according to the weight of the gun. For a 27-pounder cannon, weighing 170 times the weight of the projectile, six discharges were to be made, the first two with $14\frac{1}{2}$ lb. of powder and two balls, the two next with $9\frac{1}{28}$ lb. and a cylinder 4 calibres long, and the last two with $10\frac{3}{4}$ lb. of powder and two balls. Gazeran substituted a different principle of proof, which has since been adopted in Sweden, the Low Countries, and Germany, and which may be called a metal proof. Bars of a determinate size were constructed of the metal used in any particular cast, and loaded until they broke, the result being supposed to afford a test of the quality of the gun; but as such a trial as this can take no account of the imperfections which are liable to be engendered in the very operation of casting *large masses*, by irregular cooling or solidification, and other causes, it is evident that no satisfactory theoretical relation can be established between the weight which breaks a bar and the force which bursts a gun. Chemical proofs are equally unsatisfactory, as it is impossible that they should embrace all the possible physical defects of a gun, which may be so local as easily to escape notice in this way. In England the proof is of two kinds—the first instrumental, being directed to the examination of the bore, having previously tested the general dimensions and weight of the gun; and the second a fire-proof, all the other proofs (by searcher, by water, and by sun) being only means of detecting any deterioration from the firing. In respect to general dimensions, not more than ·3 of an inch variation is allowed; in the diameters of the bore not more than ·033 inch in 42 to 18-pounders, and ·025 in 12 to 6-pounders; and in the position of the bore as regards the axis ·5 in the 42 to 18-pounders, and ·334 in the 12 to 6-pounders. In the fire-proof, each gun is discharged twice with charges exceeding one-half the weight of the projectile, excepting in the 68 and 56-pounders; one shot and two high junk wads, the actual charges being as below:—

Nature of gun,	42	32	24	12	9	6	3
Charge in lb.,	25	$21\frac{1}{2}$	18	12	9	6	3

The proof charge of the 68-pounders is 30 lb., and that of the 56-pounders 28.

After the firing the searcher is used, and any cavity of

·2 of an inch depth behind the first reinforce, or one of ·25 before it, condemns the gun. Water is then forced into the gun by an engine, in order to detect fissures by its percolation through the metal, and subsequently the bore is examined internally by light reflected from a mirror, in order to detect minor flaws by their retention of water, which constitutes the sun proof. Should any one gun of a lot burst, all the others are subjected to another proof.

In respect to these modes of proof by firing with extraordinary charges of powder, it may be justly objected that they are rather proofs of the strength of a gun before firing than of its strength after firing; and it is scarcely possible that the discharge of an extreme load should not more or less modify the condition of an iron gun in respect to its power of resistance. It is thus that guns are found to burst unexpectedly in service with ordinary discharges, which have gone through the proof without exhibiting any deterioration; and this is by no means surprising, as the locality of the injury may often be entirely out of the reach of the test devised for its detection. In the proof charges used in our service there is even an unnecessary exaggeration of the principle in guns of the lesser calibres; for though in the 24-pounder the proportion of the weight of the gun to that of the projectile is as 233 to 1, whilst in the 12-pounder it is 196 to 1, the proof charge in the first is only three-fourths of the weight of the projectile, or 2·25 times the service charge, and in the last equal to that weight, or three times the service charge; and it is difficult to account for such high proof charges, unless the object of proof were to determine the absolute strength of the gun rather than simply to ascertain its ability to resist a regular charge under ordinary circumstances. It may be justly said that firing a few rounds with a moderate charge, combined with a knowledge of the quality of the metal and of the care used in casting and boring, would insure more effectively safe ordnance than the use of excessive charges; but this requires that the gun foundries should be under an artillery inspector as they are in Spain, the foundry of Trubia having been especially established by the Spanish government for that purpose.

Iron guns, how procured, and result of proof.

At present the greater portion of the iron guns are cast for the ordnance by Messrs Walker of Gospel Oak, and by the Low Moor Company in Yorkshire, for which Mr Hood is the agent. The guns are cast solid, are then bored and brought to Woolwich, and having been previously weighed, are subjected to the proofs already detailed. Taking the average of ten years, 64 in a thousand are rejected by the instrumental proof, or about $6\frac{1}{2}$ per cent., and 44 in a thousand, or about $4\frac{1}{2}$ per cent. by the fire proof; and this latter number is sufficiently great to warrant the belief that many more may have suffered considerable deterioration under so severe a trial, from the defective elasticity of cast-iron, although of a nature to escape detection by the searcher, or by the auxiliary water and sun proofs. It may be here observed that the Sardinian government have obtained iron ordnance from one at least of the Yorkshire foundries, as many of the guns mounted upon the new works of Genoa are of their make; and in respect to their mounting, they possess the peculiarity of being placed on iron garrison carriages, so high as to fire "en barbette" over the parapet with only a very slight elevation of the mound or platform on which they rest. This arrangement is intermediate between the ordinary garrison carriage and a traversing platform, and may under some circumstances have its advantages.

Cannon of cast-iron reinforced by wrought iron.

The insufficiency of mechanical means to construct easily and cheaply wrought-iron guns, as well as the impossibility of giving to cast-iron a large amount of elasticity without interfering with its hardness, have led to the proposal of strengthening the cast-iron gun by reinforces of wrought-iron. Several modes have been devised of effecting this object; that of M. Thiery consists in the use of both bars and hoops applied in the following manner. Bars of the same length as the piece are heated to a suitable temperature, and then arranged in grooves formed for the purpose in the interior of the mould, at about 8 inches apart, the number and thickness of the bars depending on the calibre of the gun. Making the cast afterwards with care, it is found that the bars adhere firmly to the cast metal. and though on the surface they are found to have undergone a steel-like modification, they retain internally the texture of wrought iron. This gun is moulded without trunnions, so that the bars extend its whole length, and protect the breech as well as every other portion of the gun. In the bars are notches at regular intervals to receive the binding hoops which, being put on at a white heat, grip the bars firmly in cooling. One of these hoops is considerably strengthened, so as to receive and support the trunnions which are welded on to it. An 8-pounder corresponding to an English 9-pounder constructed in this manner, with 12 bars and 36 hoops, the former $\frac{3}{10}$ths and the latter $\frac{4}{10}$ths inch thick is stated to acquire, by such an armature, a resisting power so great that it is probable a 9-pounder might be bored up to a 12-pounder, and be then efficient for the projectile and charge of that calibre; and thus, that it would be possible to replace bronze field-guns by iron guns of this description at about one-fourth the cost. It should be observed, that casting without the trunnions simplifies the process of moulding, and induces more uniformity in the cast; but the subsequent operation of attaching the trunnions by welding them to the hoops is not without much mechanical difficulty.

The necessity of casting guns of sufficient weight to prevent a violent recoil, and the consequent rapid deterioration of the carriage, will doubtless render our authorities disinclined to adopt guns of this description; but in mortars intended to be fired at high angles, the use of a wrought-iron armature would render the adoption of very heavy projectiles more practicable than they are at present, and it is thus that in Belgium mortars of the calibre of $23\frac{1}{2}$ inches, and capable of projecting a shell weighing half a ton, are secured from bursting by wrought-iron hoops.

Compound cannon of iron and bronze.

It has been proposed to cast a compound gun of iron and bronze, and it is said that a gun of this description was cast in India in 1666. In modern times several such guns have been constructed; as at Strasburg in 1802 and 1819, at Turin in 1812, and by M. Martin in 1821 and 1822. The object of such a system is to obtain a core of either wrought or cast iron for the bore of the gun, and by covering it with a metallic envelope of higher elasticity and tenacity to diminish the chances of explosion. It is said that in these experiments a perfect union was established between the bronze and iron; but that the results of proof were not satisfactory. Again, in 1826, three 24-pounders were made on this principle, the bore in one having been formed of short tubes of forged iron placed one above the other, so as to give the necessary length of bore, whilst in the two others tubes were used only of sufficient length to form a chamber for the charge and ball, the tubes being either of wrought or cast iron.

System deserves trial

When it is remembered that the great defect of bronze guns is, that they rapidly wear, or, as it is technically called, droop at the muzzle in active service, it may be suggested that this union of a wrought-iron bore, with a casing of bronze, deserves a trial at our arsenal, and seems to admit of very easy manipulation.

Alloy of iron and copper.

The attempts which have been made to use mixtures of iron and copper by melting the two metals in separate furnaces, and then mixing them in a reservoir before taking the cast, scarcely require observation; as the great difference in the fusibilities and affinities for oxygen of the two metals, as well as the small affinity of one for the other, render such alloys unnatural.

Cannon.

Bronze cannons.

Under this term may be arranged all alloys of copper, whether binary or ternary. The epoch of the first economical application of copper is lost in the darkness of the most remote antiquity; and the first use of an alloy of that metal in the construction of arms must be also referred to a very early epoch, as bronze is mentioned by Homer. The ruins of Pompeii and Herculaneum have exhibited to the moderns the skill in working bronze attained by the ancients; and the numerous Celtic swords and other warlike implements discovered in Ireland and other countries testify to the fact, that bronze was the material commonly used for the manufacture of arms, before the more intractable metal iron had been brought under sufficient control, partly to replace it for that purpose, and entirely for many others.

Tin, the other constituent of true bronze, was also known from the very earliest epoch; but zinc was not known in Europe as a distinct metal till the twelfth century, when it was introduced as such from China; and it was only about the middle of the last century that the method of extracting it from its mineral ores was discovered. The ancients, however, had unconsciously applied zinc to practical purposes in the manufacture of brass, which they produced by the direct action of the ores of zinc, either blende or calamine, on copper. The name zinc was given to the metal by Paracelsus at the beginning of the sixteenth century.

In respect to the first use of bronze cannon, the Spanish authors we have so freely cited state that the Moors used machines of cast metal for projecting stones in 1220, which may be assumed to have been bronze cannon, as the art of casting iron is of so much more recent date—at least the art so far as concerns the casting of large objects. The train which was prepared for the Andalusian war, in the reign of Henry III., in 1406, consisted of 6 bombards, and 100 lesser pieces, many of which were doubtless bronze guns; the probability indeed is, that the Spanish Arabs were our first instructors in this branch of war, just as they appear to have been our precursors in the institutions of chivalry, and that these warlike arts passed from them, through the Spaniards, to the other countries of Europe. In the wars of Charles V. against Francis I. of France, a great quantity of bronze cannons of various kinds, cast at Malaga, were used in the emperor's army, and so rapidly were such instruments of war multiplied, that Philip III., in 1609, issued an ordinance by which the number of bronze cannon foundries was limited to four within the peninsula, and four in the Spanish territory without it; and the number of calibres restricted also to four, a remarkable anticipation of a wise simplicity in the arrangements of war. The oldest bronze gun, with a legible date attached, now existing in Spain, was found in the Alhambra of Granada, in 1814, and was cast in 1501. Several others of the date of 1542 are also in the Alhambra, and one of probably much greater antiquity, which bears, in Gothic characters, this inscription, "*Præceptum mei domini facio, fugite a me omnes.*" In France, at Toulouse, there is a bronze gun cast in 1438, and in 1478 Louis XI. ordered artillery of this description to be cast at Paris, Orleans, and Tours, the epoch of which was marked by the death, at Tours, of the founder, Jean Moqué, who was killed by the bursting of one of his own guns. In Germany bronze guns were cast at Augsburg in 1372, and in Italy in 1399, and it is very probable that both countries derived the art from Spain. In England the industrial resources of the country have naturally led to a preference for iron guns; but it would appear, from the fact that bronze guns formed part of the armament of the Mary Rose, sunk off the coast of France in 1545, that at least prior to that date bronze guns had been used, if not cast, in England. The curious compound guns of the date 1426, formed of iron bars with a brass cylinder as part of the bore, connected with a moveable breech, belong to the section of forged guns.

Cannon.

Early guns made of a ternary bronze.

The bronze guns cast before the middle of the last century are supposed, from such chemical examinations as have hitherto been made, to have been formed of a ternary compound of copper, tin, and zinc. The latter, as before observed, derived from the calamine ore, a carbonate of zinc. In the early ages, each founder had his peculiar compound, and, guarding his secret under the veil of profound mystery, transmitted it as a legacy from father to son. So many of these guns burst, or became rapidly useless in service, that during the Thirty Years' war, bells were melted and used for casting guns. The proportions of some of the foundries, after the Thirty Years' war, were as follows:—

	Keller.	Buchner.	Other foundries.
Copper,............	91·5	89·9	86
Tin,..................	7·8	8·6	11·1
Zinc,..................	0 7	1·5	2 9

The zinc being introduced into the compound through the intervention of its binary compound with copper, a proportionate quantity of brass having been actually used in forming the metal for casting. The ternary gun-metal has even very recently had its advocates, and it is said to be still used in Denmark; but when the difficulty of insuring certainty in the proportions of the alloy with a metal like zinc, so volatile at a very moderate temperature, is considered, there can be little reason to depart from the binary compound now generally adopted.

The proportions adopted are different in different countries; in France, 11 per cent. of tin; in Spain the same for large calibres, or 8 per cent. for small calibres and for mortars and howitzers; and in England 10 per cent.; and in our service the proper line appears to have been drawn in respect to the use of iron and bronze—the heavy ordnance of garrison and siege artillery being constructed of iron, and the lighter ordnance for the field of bronze.

Casting of guns.

Of the several modes of casting which have been adopted at different times and in different countries, two only are at present in use in cannon foundries, namely, casting in sand, and casting in prepared earth or mould; the first for iron and the second for bronze ordnance. By casting iron guns in sand, a hard skin, as it were, forms on the metal, and it is unnecessary to subject the gun to turning, and this is gaining a great advantage in iron guns.

Dry sand moulding.

The sand for dry sand mouldings is made by mixing a quantity of sharp refractory sand with water in which clay has been diffused. After the mixture is thoroughly made, if a handful is grasped, and on opening the hand the sand retains the form given it, then the consistence of the mixture is good. The sand should have the following qualities:—1*st*, It should not be fusible by the heat of melted cast iron; if it were, it would adhere to the metal, and make the surface of the gun rough. 2*dly*, It must be sharp, and composed of angular particles; if the particles of the sand were round, it would not hold together on taking out the model. 3*dly*, It must not contain too much clay, for in that case it would crack in drying. 4*thly*, It must contain a certain proportion of clay, to retain the form that the model impresses on it.

The model.

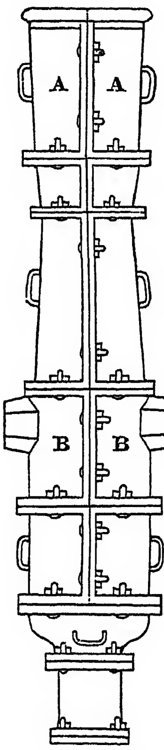
For dry sand moulding, a pattern of wood may be used, turned exactly to the form of the gun; or, to avoid expansion from humidity, the model, or pattern as it is termed in the foundries, may be of metal. Brass or pewter are preferable to iron for making patterns, as a smooth surface may be more easily given them, so that they may leave a correct impression, and may come out well from the sand. The metallic pattern is hollow, that it may be lighter and more easily handled: it is also in different pieces; and each piece fits into the adjacent piece by a rebate.

The length of each piece of the model should be a very little greater than the given length of the corresponding part of the gun, because the length of the mould is the length of the gun whilst hot, and this is longer than the

length of the gun when it comes to the temperature of the atmosphere, at which temperature the dimensions of the guns are given. It has been estimated that some kinds of cast iron contract six hundredths of an inch in a foot in passing from the liquid state to the temperature of the atmosphere. This contraction is not considerable enough to be taken into consideration in the diameter of the pattern. The shrinking of the sand in drying, though not considerable, tends likewise to make the piece shorter, and is another motive for making the pattern a little longer than the dimensions taken from a gun at the usual temperature. The patterns of the trunnions are attached to the pattern of the second reinforce by screws, so as to be unscrewed and separated when the pattern is to be lifted out of the sand.

Gun-boxes.

The gun-box, in which the dry sand mould is to be formed, is of cast iron, and cast in sand. It consists of several portions; each of these portions has a flange, by which it is fixed to the others, and the whole, when connected together, form the gun-box. In the flanges are holes through which bolts are passed; the bolts are secured by wedge-formed keys; thus the different parts of the box are firmly held together. The two portions of the gun-box which contain the breech-ring and cascabel are single, not being divided longitudinally. Each of the other five transverse portions is divided longitudinally into two. A handle is fixed to each portion of the box, for the purpose of moving it. The upper transverse portion AA contains the gun-head. In each of the two portions BB, which contain the second reinforce, there is a lateral projection for the trunnions. The figure represents the gun-box with the breech lowermost, in the position in which it is placed when the metal is poured in.



Forming the mould.

To make the mould, the pattern of the breech is first placed on a board, and the corresponding portion of the gun-box is put over it, and sand is rammed between the pattern and the box. The flat exposed surface of the sand is painted over with blacking, which consists of charcoal and clayed water, that there may be no adhesion with the sand of the next portion of the mould. The pattern of the first reinforce is now fitted into the pattern of the breech, and the corresponding portions of the first reinforce box adjusted on the flange of the breech-box. Sand is well rammed, in small quantities at a time, between the pattern and the box; and the upper flat surface of the sand is painted over with blacking. The mould is completed by adding the remaining pieces of the model and of the box, one above another, ramming the sand, and painting the transverse surface of the sand at the top of each division of the box with blacking. The sand must be strongly and equably rammed, that every part of its surface may be able to resist the pressure of the liquid metal. Three little wedges are interposed between the two adjacent transverse portions of the box, that the sand may project a little, so that after it is dry it may be flush with the box; if this were not done, there would be an interval between the adjacent surfaces of the sand, through which the metal would pass and form a fin.

Drying stoves.

When every part is moulded, the box is taken to pieces, and the parts of the pattern are carefully taken out of the sand, for which purpose they are first struck with a wooden mallet. Each part of the mould is then carried separately to the stove to dry. The stove is a room twelve or fifteen feet square, with large iron doors on one side; the fire is made in a large conical grate placed on the middle of the floor; the smoke issues by an aperture in the brick ceiling. The heat in this stove is considerable, but it must not be so great as to make the boxes red hot; for then, by the expansion of the iron, the mould would be injured; the moulds take about fifteen hours to dry in this situation. When the moulds are taken out of the stove, their interior surface is painted over with a coat of blacking, that there may be no adhesion between the mould and the metal.

Putting together the mould.

The pieces of the gun-box containing the mould are then taken to the pit, and being carefully placed the one upon the other by the crane, they are put together, and secured by their bolts. The mould is placed with the breech undermost; the axis of the mould is made perpendicular to the horizon by a plumb-line, that the weight of the melted metal may press equably, and not more on one side of the mould than on another. It is not necessary that sand should be rammed round the mould, the box being strong, and its parts firmly bound together, so as to require no additional support. The mould is now in a position for the metal to flow into it through its open end, which is the extremity of the head.

Air furnace.

The pig-iron from which the gun is to be made is melted in a furnace, called an air-furnace in the iron foundries, and termed by some authors a reverberatory furnace. The flame of pit-coal is carried by a current of air so as to play upon the pig-iron. The stack of the chimney is 40 feet high. By the pressure of the unrarefied external air on the lower part of the rarefied column of air in the furnace and chimney, the current of air through the furnace is produced. The grate G is larger than any other transverse section of the furnace. (See figure next page.) The furnace has three openings; one, C, for introducing the coals; the second, P, which has a sliding brick door, with a counterpoise, serves for introducing the pig-iron. The third, I, is for the purpose of stirring the metal, and taking out the melted iron for small castings by iron ladles coated with clay, and made red hot. This third opening has a door of fire-brick; the joints between the door and the door-frame are luted. In the middle of the door is a hole, through which the state of the melted metal may be seen. There is likewise a smaller opening, T, for letting out the melted metal.

The furnace and stack are of brick. The interior of the furnace is a coating of fire-brick, nine inches thick, detached and separate from the outer coat and the other parts of the building, in order that the heat may not melt the common brick of which the outer parts are composed. The fire-brick is made of refractory clay, which, containing little iron, and little or no calcareous matter, burns white, and sustains a great heat without melting. These bricks are made of Stourbridge clay, or of a light-bluish gray stratified clay, found in the strata that accompany coal in some of the collieries in Scotland. The clay is first ground, the pieces of ironstone picked out, and then made into bricks. In making the interior coating of the furnace, the bricks must be built with moistened fire-clay, and not with lime-mortar. The quantity of metal put into the furnace should be equal to the weight of the solid unbored gun with its head, and something more in case of need. It requires a large air-furnace to contain metal enough for one large gun.

Quality of the iron.

The pig-iron for guns should be gray, that kind having most tenacity; white pig-iron is too brittle, and so hard that the head cannot be cut off, nor the gun bored.

Charging the furnace.

A bed of sand, N, is made in the furnace, on which the pig-iron is to be laid. The furnace is heated to a white heat, till the sand is vitrified, which is known to have taken place by touching the surface of the sand with an iron ringard. The brick door is then lifted up, and the pig-iron is

Cannon.

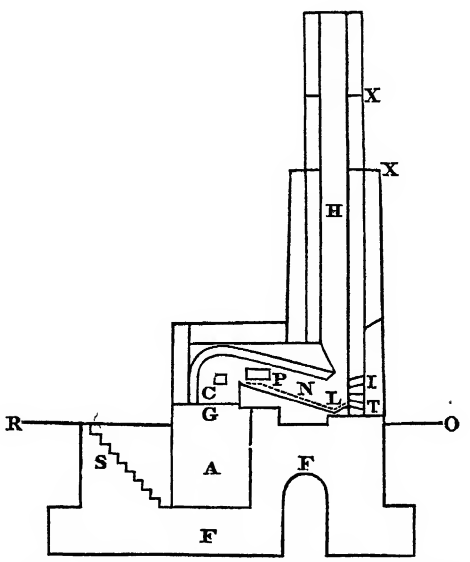
Fusion should be rapid.

laid on the bed of sand. The heat should be applied so as to produce a speedy fusion; for if the iron is long exposed to heat before melting, a portion of its carbonaceous matter is burnt, and it passes from the state of gray cast-iron to that of white. In situations where pit-coal cannot be had, wood may be used in the air-furnace; but the heat given by wood is not so great as that produced by pit-coal. To obtain the utmost heat that the wood is capable of affording, it should be well dried, cut into small logs, and the logs should be placed with their end upon the grate.

The pig-iron melted by the flame playing on it flows down into a cavity, L, which has a hole T, opening outwardly, and stopped with clay. When the hole is forced open by a workman, the metal issues and is conveyed by a gutter formed of sand to the gun-mould, into which the melted metal falls through the open end of the head. The sand forming the gutter should be in a proper state of moisture. If it is too dry, some pieces of it will be carried away by the metal. Across the gutter is a dam composed of an iron plate luted, and dipping a little below the surface of the metal to retain the scoriæ. This dam is driven down to stop the current of metal when the mould is full. The metal is also skimmed, as it passes along, by a skimmer, composed of a rod of iron terminated by a flat semi-elliptical piece luted and made red hot. It is sometimes the practice to plunge a piece of green wood for a short time into the head whilst liquid. This is with a view to prevent honeycombs, and its action may be to metallize any oxidated particles of the metal, and that the vapour from the green wood, rising to the surface of the metal, may carry with it small air bubbles, or other extraneous bodies that would, if they remained, occasion cavities in the metal.

Explanation of the figure.

The figure is a transverse section of the air-furnace. C is the opening through which the coals are introduced. P, the opening at which the pig-iron is thrown in. T, the hole through which the metal is let out. The metal flows into the casting-house. O, the floor of the casting-house. In this floor is the pit in which the moulds of large goods are sunk, that the metal may flow down into them. I, the door, with a hole in it, for seeing the state of the melted metal.



G, the grate. L, the lower part of the cavity of the furnace, into which the metal, as it is melted, flows. S, steps leading to A, the ash-pit. N, bottom of the furnace, lined with sand. H, chimney; the height of the stack is forty feet from the surface of the ground. The stack is strengthened in different places by iron bars, X. F is the mass of building which forms the foundation built below the surface of the ground to support the weight of the furnace and stack. R, the surface of the ground out of doors. C P N L H is the course that the flame takes.

Not cast from the blast furnaces.

The guns are not cast from the blast-furnace, where the ironstone is melted, as the quality of the metal would be uncertain, and might vary from one cast to another, by causes either unknown, or not under the control of the iron-master. On the other hand, in the air-furnace, pig-iron of a quality proper for making guns is put in, and the quality of the iron is not materially altered by the process of melting.

The head.

The head of the gun is like the jet (gate or geet of the workmen) of any other casting. Whilst the whole is liquid, the head is a column of liquid metal that acts by its height, exerting pressure on the metal that forms the body of the gun. The metal subjected to this pressure whilst liquid is less subject to porosity when cooled. The head also furnishes metal to fill up the cavities that occur in the piece by the contraction and crystallization of the metal whilst it is passing to the solid state. All the great contractions and crystallizations are thus transferred to the surface of the head, which is found to be composed of large cavities, sometimes containing cast-iron crystallized in a fern-leaf shape. The head also serves to receive any impurities that may have escaped the attention of those appointed to skim the iron as it flows along the gutter.

In 10 or 12 hours, the piece is sufficiently cool to be removed. It is then stripped of the mould, and taken to the boring-mill, to undergo the operations described under our article Boring of Cannon. Mortars, howitzers, and carronades, are moulded, cast, and bored in the same way as long guns.

Pit-coal cannot be employed entire in the blast-furnace; the bituminous part would be conglutinated by the heat, and the furnace would be choked, and the materials would no longer descend gradually as they ought to do. The coal is therefore burnt to drive off its bitumen, and it is then in a state of cinder, and called coke. It requires a larger mass of coke than of charcoal to smelt ironstone. Hence the coke blast-furnaces are large, and the machines employed to blow them are more powerful than the wooden spring bellows invented in Germany in 1620, and which continue to be employed in the charcoal iron-furnaces in Germany and France. Bellows connected by leather, and worked by water, were used to blow the blast-furnaces at Carron at the commencement of that establishment in 1760. Some time after, these bellows gave place to blowing machines, composed of pistons working in iron cylinders, constructed by the celebrated Smeaton, and described in his reports. The blowing machines of the blast-furnaces in Britain are now always composed of pistons moving in iron cylinders. The improvements in the steam-engine have rendered practicable the working of blast-furnaces in situations where there is no fall of water; and, on the other hand, the manufacture of the various parts of numerous steam-engines has called forth the abilities and ingenuity of the iron-founder.

In consequence of the advanced state of the English cast-iron manufacture, several foreign nations have been desirous of introducing the English method, and have procured English workmen for that purpose. In this way iron-works on the English plan were erected in Russia about 1780, in Silesia in 1790; and in France, at Creuzot, 12 miles south of Autun, there were three English coke blast-furnaces begun about 1790, under the direction of William Wilkinson.

Progress of the art of casting cannon.

The improvements in casting cannon, as in other arts, have been gradual. They are now always cast solid, experience having shown that guns cast solid are stronger, and less liable to burst than those cast hollow, and that the bore is freer from honeycombs, and more likely to have the same axis with the piece. The second of these qualities is still more certainly attained by the practice now in use of making the gun itself revolve whilst boring; in this way, as long as

the boring bar remains unmoved, the axis is right; but if the boring bar has a conical motion, then the point of the bit is out of the axis; when the boring bar was made to revolve, the bore might deviate greatly from the axis. The improvements in the casting of cannon have kept pace with the improvements in the manufacture of cast-iron.

The art of casting iron was known to the ancients, as appears from a small antique statue of Hercules of cast-iron, dug up at Rome. In China it appears to be practised with a dexterity visible in the Chinese specimens of many other arts. In modern Europe it has grown with the general advancement of society, and has now arrived at a high state of perfection. In the Prussian dominions small statues and other objects are cast in iron, and then bronzed; and from the great taste with which they are designed are highly ornamental; but in none of the other countries of Europe has so large a capital been embarked in the manufacture of cast-iron goods as in England, and their use, in some shape or other, is general throughout the British dominions. Pit-coal has been the main instrument in the development of this highly important manufacture, and Great Britain is indebted to its possession of such vast coal deposits for the extension and success of its iron-works. Pit-coal began to be used for smelting ironstone in 1619, the first operation having been performed in Worcestershire by Dudley, who describes the process in a book entitled *Metallum Martis.* The manufacture of cast-iron was not much advanced 100 years afterwards; for, in the first half of the eighteenth century cast-iron goods were imported from Holland, and the Dutch chimney backs, with the figure of a parrot, are yet to be seen in old country houses in Scotland. The minerals used are the hæmatites of Ulverstone, and the neighbourhood of Whitehaven, which, being very rich in iron, are carried by sea to smelting furnaces of other parts of Britain; and the argillaceous iron ore which is interstratified with the beds of coal of the great coal-fields, on which, therefore, the principal iron-works of Great Britain have been established.

Moulding in earth or prepared mould.

Bronze cannons are cast in earth or prepared mould, which is composed of clay, sand, cow-hair, and horse-dung. The clay, from its tenacity, the facility with which it can be moulded into any shape, and its property of hardening on drying, forms the basis of all moulding earths, whilst the defects it possesses of cracking and shrinking as it dries, are corrected by the addition of sand or silicious earth. Sands or earths containing much calcareous carbonate should be rejected, as the disengagement of carbonic acid upon contact with melted metal would produce air-bubbles; and ochreous earths should be also rejected, as the metallic oxides they contain may vitrify the first coats of the mould. The cow-hair adds to the tenacity of the earth, by binding its parts together, and diminishes the contraction or shrinking; and the horse-dung renders the paste more unctuous and cohesive, and more readily dried. All these substances undergo distinct preparative processes before they are mixed together, in order to free them from extraneous substances, and to make them fit for blending readily together; the earth being first mellowed by exposure in pits when moistened by a sufficient quantity of rain-water.

Three descriptions of moulding loam are used in the French foundries, viz., fine earth, putty, and common earth. The *fine earth* is a mixture of four parts of mellowed clay and one part of horse-dung, which is allowed to rest in the tubs for at least eight days, and is then used as a pulp, after having been passed through a very fine sieve. The putty consists of four parts of *fine earth* passed through a coarser sieve, or a perforated copper basin of three parts of silicious sand, and $\frac{1}{8}$th part of cow-hair. *Common earth* consists of two parts of mellowed clay, one of rather coarse silicious sand, one-half part of horse-dung, and one-half part of cow-hair. Each of these compounds is prepared separately on an oak table, and the various substances of which they consist are arranged in layers one upon the other, and then carefully triturated together with proper tools, so as to ensure a smooth and homogeneous mixture. The proportions vary in different foundries; but it is necessary to keep to moderate and fixed quantities of cow-hair and horse-dung, as these substances burn, and if in too great quantity may produce cavities in the coats of the mould into which the metal, when in fusion, would necessarily filter. In Spain the *common earth* is made by spreading on the table 584 lb. of prepared clay, and over that 36 lb. of horse-dung; and as a third layer $2\frac{1}{2}$ lb. of cow-hair; 69 lb. of water being then added, and left for $1\frac{1}{2}$ hours, so as to allow the whole mass to be penetrated by the water, when the operation of mixing commences, and is continued for about three-quarters of an hour, after which it is generally found that the three materials have been perfectly combined together.

Moulding in prepared mould or loam.

The operation of moulding is divisible into two parts, namely, the preparation of the model and the formation upon the model of the mould.

Model.

The model, as well as the mould, is formed of three distinct parts, namely, the models of the body of the gun, comprising part of the first and the second reinforces, the chase, and the muzzle; of the breech and cascable, and of the head metal. The model of the body of the gun is built up on a conical spindle of wood, either of pine or fir, which is supported horizontally, by its ends resting in the sockets of the vertical end-pieces of a frame firmly fixed to the ground. The large end of the spindle has a shoulder in the shape of a truncated cone, which, resting in a hollow or notch of the frame, prevents any longitudinal motion, and this shoulder is terminated by a square head pierced with lever holes, into which the handles are placed, by which the model and the mould in progress of formation may be turned as required. Each frame supports two spindles placed opposite each other, but in reverse positions, so that two models may be prepared at once. In well-arranged foundries the frames are constructed of cast-iron, and made moveable on trucks and rails, so that their position may be shifted; and as it is necessary to dry the model and mould in course of formation, the frames are placed over a brick pavement made slightly concave for the reception of the fuel. The external form of the model is regulated by a profile board, to one edge of which is attached throughout its length an iron plate cut so as to correspond exactly to the various rises, depressions, mouldings, &c. of the intended gun. This profile is fixed to the uprights of the frame, either horizontally at the level of the axis of the spindle, or vertically below the spindle; and as the spindle is turned round during the process of forming the model, every part of it is reduced to its true shape and size, or rather to a size somewhat greater, as the profile is so placed as to produce an increase in the diameter of the gun of about half an inch, which allows a sufficient thickness of metal for the operation of turning. The spindle and profile-board being properly placed, the first act of the moulder is to fix brackets, shaped to the swell of the muzzle, at regular intervals all round the smaller end of the spindle, and to fasten them on with long nails; he then covers the spindle with straw-rope, winding it round from the muzzle end backwards; and when the rope circles have sufficiently bound the brackets which define the swell of the muzzle, he withdraws the nails by which they had been at first secured in position, and continues the straw coating until there remains only an interval of one or two-tenths of an inch between it and the profile-board, which space is then filled up by a coat either of prepared clay, or plaster of Paris, the last layer being put on in a finely liquid state, so as to fill up all cracks, and efface any defects; the spindle being turned during the operation, so as to bring every point of the surface into contact with the profile-board, by which it is as it were turned into proper shape. The model of the

Cannon.

body of the gun being thus finished, the models of the trunnions and dolphins (if any) are next attached to it. These models are made of plaster, cast in plaster moulds; and those of the trunnions are, from their bulk, cast hollow. The trunnions and dolphins having been carefully secured in their proper places by straps, and cemented on by liquid plaster the model is complete, and the workman then proceeds to form the mould upon it.

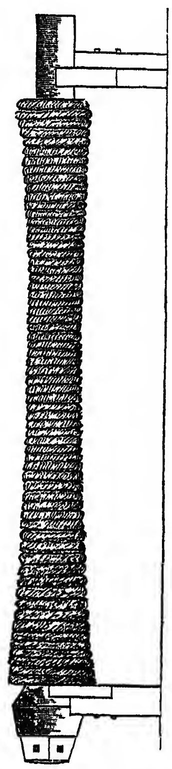
Formation of the mould.

The model is first brushed over with a wash either of finely comminuted and well-washed ashes, or with tan-ashes diffused in water, the object of this coating being to prevent adhesion between the model and the mould. The ash-coat being perfectly dry, the moulder applies three successive coats of putty loam, being in all about $\frac{6}{10}$ths of an inch thick, all being slowly dried in the air, with a mixture of putty and common loam. Several other coats are then added, gradually increasing in thickness, and dried by artificial heat so as to render them hard enough to resist the point of a knife; and these are followed by thicker layers of common moulding loam, until a thickness of about $2\frac{3}{4}$ inches in guns of large calibre, and $2\frac{1}{4}$ inches in those of lesser calibre has been attained. The surface is then carefully smoothed, and any irregularities having been removed by the application of a profile-board, the first armature is fixed, which consists of flat bands of iron of the length of the mould, secured by circular iron bands at fitting intervals, these hoops being well closed by iron wire. In guns of large calibre, such as the French 16-pounder and 24-pounder, 10 or 12 bands, and 16 or 20 hoops are used. The bands and hoops are 2 inches wide; the bands being $\frac{4}{10}$ths of an inch thick, and the hoops between $\frac{3}{10}$ths and $\frac{2}{10}$ths. Before putting on the bands some iron wire is wound round the mould at both ends and at each side of the trunnions, and by this wire the bands are tied down to the mould, and thus kept firmly in place until the hoops have been put on and closed. The armature being thus fixed, the moulder fills up all the spaces between the bands and hoops with common loam, and puts fragments of brick into any open spaces between the bands and hoops. He then applies over the whole surface a new coat of coarse loam, which he dries as before, and continues the operation, by successive coats, until the mould has acquired a total thickness of 5 inches for large calibre, and 4 inches for small; and as these dimensions have been found sufficient to insure stability in the mould, they should not be exceeded, as a greater thickness would only add to the difficulties of drying and baking. The moulder now smooths and trims this last coat, and having strengthened the region of the trunnions by hoops let into the substance of the loam, proceeds to attach the second armature of bands and hoops, which are somewhat stronger than the first, and terminated by hooked ends, by which they may be secured to the bands of the breeching and head-metal moulds; on this second armature one or two more coats of loam are spread, and the whole being smoothed by the hand, the mould is complete. The spindle and the straw bands are now withdrawn, and such portions of the plaster which do not come off with the straw being carefully extracted, as well as that which formed the moulds of the trunnions and dolphins, the mould is ready to be baked. The models and moulds of the breeching and head-metal are formed upon the same principles as that of the body of the cannon, except that in the model of the breeching, an iron axis is used instead of the wooden spindle; the axis and profile-board being sometimes horizontal for small calibres, and vertical in large calibres, in consequence of the greater thickness and heavier armature of the moulds. The moulding with a vertical axis is carried on over a small round furnace heated with wood, and surmounted by a cast-iron drum, which can be raised or depressed for either moulding or drying. The axis is in this case fixed, being firmly attached at its base to the platform of the furnace, and the profile-board is moveable, being fixed to an iron plate, which turns on a shoulder of the axis. The model being finished, the mould is formed upon it in the same manner as in that of the body of the gun; but the second armature is replaced by an envelope of iron or bronze, called the goblet mould, into which the mould is cemented either with plaster or loam, and from which it acquires strength to support the whole weight of the metal. The mould being completed is then dried by fire, and this is effected at Toulouse by a circular furnace with a central hearth sufficiently large to dry ten moulds at once; the ten stoves being arranged circularly round the hearth, and covered as required by a drum of sheet-iron. The model of the tail piece itself of the cascabel is made of bronze, and is used for all guns of the same calibre. The final hardening or baking of the moulds requires special precaution in respect to that of the body of the gun, on account of its length, and it is therefore effected in the casting-pits by suspending the mould over a small temporary brick furnace, which is removed after the operation. The three pieces which constitute the whole mould of a cannon being now ready, they are lowered into the pit and properly adjusted to the breech below and the dead-head above, each part being firmly secured to the other two by iron wire passed round the hooked ends of the iron bands of the armature, and the joints well plastered with moulding loam. The mould now forms one complete whole, and the moulds of all the cannons to be cast at the same time are carefully arranged in the pit, so that their summits should all be on the same level, and the top of the dead-head level with the lower discharging hole of the furnace. The whole pit is now filled up with slightly damp earth, put in by successive layers, gradually increasing in thickness from below upwards, and carefully rammed with an iron rammer. In the moulds of large guns, the breech and body of the gun are first connected together, and the dead-head mould fixed on when the pit has been filled up to the level of the muzzle. The ramming is a delicate operation, and much care is required to avoid a blow on the trunnion portion of the mould, an accident which in some foundries is guarded against by small stakes placed around the trunnions as a guide to the workman. When the filling has come up to about $1\frac{1}{4}$ inch of the discharge hole of the furnace, canals are formed in the earth of the pit for conveying the melted metal to the different moulds, the sides and bottoms being of bricks well cemented and plastered with moulding putty, and the pit is then filled up to its summit, when everything is ready for the casting. The system which has been here described is that adopted in the great cannon foundries in France, in which country even siege guns of the largest calibres are manufactured of bronze, and is, with some slight modification, that of our own arsenal.

Shell Moulding.—This description of moulding is also effected in loam, but far more expeditiously than the preceding. The model is either of wood or brass turned to the exact shape of the particular gun, with the addition of the dead-head; and serving, therefore, for all guns of that calibre. It is divided into two halves by a plane passing through the axis; and one half being placed on a horizontal plank, the model is covered by a coat of moulding loam sufficiently soft to be readily applied to the model by the simple pressure of the hand, and about $1\frac{1}{2}$ inches thick. Numerous holes are then made over the surface with the finger to the depth of about one-third of an inch, and the whole is dried with lighted charcoal placed in lumps upon it until it has begun to harden, when a thick coating of plaster is applied, which fills also the holes, and thus binds the two coats together. An armature is now applied consisting of strong iron bars, both longitudinal and transverse, fixed one to the other by rivetted bolts, and over this armature a second thick bed of plaster; so that the armature is as it were imbedded between the two coats. The one half

Cannon.

being finished, the mould is turned over, and the model having been taken out, the hollow is thoroughly dried by live coals, and the interior surface brushed over by a liquid paste of clay to fill up cracks or other defects, when an ash coat is applied as in ordinary moulding to prevent adherence. It should be observed that the models of the trunnions and dolphins are made separate, and are attached to the body of the model by long screws, being removed by unscrewing when the mould has been completed. The two halves are now carefully adjusted to each other, and secured by bolts passing through the transverse bars of the armature; after which the joints are plastered up and the mould is complete for lowering into the casting pit. Another mode of shell-casting is only a slight modification of the above: the model is laid with its longitudinal axis horizontal, and one-half immersed in a bed of sand. Upon that part of the model which projects above the sand successive coats of loam are applied, and dried one by one by fire, till the model is covered with a coat of loam four or five inches thick, when an iron carcass is applied, and over the carcass another coat of loam. The mould with the model in it is now turned, so that the half already covered with loam shall be lowermost. The plain surface of the loam which had been in contact with the sand is painted over with a coat of blacking, composed of finely-powdered charcoal mixed with clayed water; this prevents the adhesion of the flat surface with the loam that is to be laid on it in order to form the mould of the other half of the gun, now of course uppermost. The two halves are secured together in the manner before described; but this method has the advantage of securing precision in the structure of the two parts by forming one upon the other. Both these methods were in use in the French foundries towards the end of the last century, but have been abandoned, as it was found impossible to prevent an escape of the more liquid portions of the metal, surcharged with tin at the line of junction. Guns cast in this way exhibit along the lines of junction, even after turning, long white streaks, which are only so many spots of tin which has filtered through, and it was therefore found impossible to secure homogeneity in the mass by this system. The process of forming the model will be better understood by the accompanying woodcut, which represents the spindle at that stage of the work where the straw-rope is wound round it, the brackets fastened on towards the lesser end, giving an approximation to the form of the muzzle. The description will, it is believed, render the remaining portion of the process sufficiently intelligible.



The importance of casting with a dead-head is very great, as the weight of the column of fluid metal forces the lower portions into all the sinuosities of the mould, and insures a homogeneous structure with a proper density. The following table gives the result of French experience as regards the weight of the dead-head, as it is evident that an excess of weight would endanger the deterioration of the mould, whilst too little weight would lead to imperfections in the mass; hence it is very important to have some guide in determining the weight from such extended experience:—

Weight of French Cannon in their different States, and dimensions of their Dead-Heads, 1838, *in Kilogrammes, the Kilogramme equal to* $2\frac{1}{5}$ *lb. Avoirdupois.*

Remarks.—At Douai the dead-head is a truncated cone, the greater circle next the piece—both diameters given in the table. At Toulouse the dead-head is cylindrical, except the small piece merging in the mould of the body of the cannon, which is a truncated cone. At Strasbourg, in guns and howitzers, a truncated cone commencing at the swell of the muzzle, and then cylindrical; in mortars of 32 and 27 cent., partly cylindrical and partly a truncated cone; in mortars of 22 cent., two cylinders of different diameters. It appears from the data given, that the weight of the dead-head in a French 8-pounder, equivalent to an English 9-pounder, is to that of the whole mass to be cast, as 1 to $2\frac{1}{10}$ths, or about 1694 lb., and that its length is about $4\frac{1}{2}$ feet, this height of metal being necessary to ensure a sufficient pressure. (J. E. P.)

CANNONADE. See GUNNERY and WAR.

CANO, ALONZO, one of the most vigorous of the Spanish painters, and, like M. Angelo, also an architect and sculptor of great merit. He must have been very industrious, from the number of specimens of his genius which he has left in Spain, particularly at Seville, Malaga, Granada, and Madrid, where we have seen and admired the boldness of his design, the facility of his pencil, and the purity of his flesh-tints, with his knowledge of chiaro-oscuro. He was a contemporary of Velasquez and Pacheco, whom he rivalled without imitating; and though we regard him as one of the most original and spirited of the Spanish school, his name and merits are scarcely known beyond the Pyrenees. Alonzo was patronized by Philip IV., and obtained the church preferment of a canon; but he was a man of ungovernable temper; and at Granada demolished a saint he had sculptured for a niggardly magistrate with a blow of his hammer, a feat which before had condemned Torregiano to the stake, in the reign of Philip II. Alonzo was born at Granada in 1600, and died there in 1667.

CANOE, a sort of Indian boat formed of the trunk of a tree hollowed, and sometimes of several pieces of the bark put together. Canoes are of various sizes, according to the uses for which they are designed. The largest are made of the cotton tree; and some of them will carry from twenty to thirty hogsheads of sugar or molasses. Others are made to carry sail, and for this purpose are steeped in water till they become pliant, after which their sides are extended, and strong beams placed between them, on which a deck is laid. The smaller kinds rarely carry sail, unless when going before the wind; their sails are made of a sort of short silk grass or rushes. They are commonly rowed with paddles, which are worked in the water perpendicularly. The small canoes are very narrow, having only breadth enough for one person, and length for seven or eight. The Indians are very expert in managing their paddles, and adjusting their bodies so as to balance their canoes, which are extremely light, and liable to be overturned. The American Indians, when their progress is impeded by a waterfall or a shallow, or in crossing the land from one river to another, carry their canoes on their heads till they arrive at a place where they can launch them again. Some nations have small vessels under the name of canoes, which differ considerably from the above, as the inhabitants of Greenland, Hudson's Bay, Otaheite, and other places.

CANON, a person who possesses a prebend, or revenue allotted for the performance of divine service in a cathedral or collegiate church.

Canons are of no great antiquity. Paschier observes, that the name canon was not known before Charlemagne; at least the first we hear of are in Gregory de Tours, who mentions a college of canons instituted by Baldwin XVI., archbishop of that city, in the time of Clotharius I. The common opinion attributes the institution of this order to Chrodegangus, bishop of Metz, about the middle of the eighth century.

Originally canons were only priests, or inferior ecclesiastics, who lived in community, residing by the cathedral church to assist the bishop, depending entirely on his will, supported by the revenues of the bishopric, and living in the same house as his domestics or counsellors. They even inherited his moveables till the year 817, when this was prohibited by the council of Aix-la-Chapelle, and a new rule substituted in the place of that which had been appointed by Chrodegangus, and which was observed for the most part in the west till the twelfth century. By degrees these communities of priests, shaking off their dependence, formed separate bodies, of which the bishops, however, were still heads. In the tenth century there were communities or congregations of the same kind established even in cities where there were no bishops; and these were called collegiates, as they used the terms congregation and college indifferently; the name chapter, now given to these bodies, being much more modern. Under the second race of the French kings, the canonical or collegiate life had spread itself all over the country; and each cathedral had its chapter distinct from the rest of the clergy. They had the name canon from the Greek κανων, which signifies three different things—a rule, a pension or fixed revenue to live on, and a catalogue or matricula, all which are applicable to them.

In time, the canons freed themselves from their rules, the observance relaxed, and at length they ceased to live in community; yet they still formed bodies, pretending to other functions besides the celebration of the common office in the church, assuming the rights of the rest of the clergy, making themselves necessary as a council of the bishop, taking upon them the administration of a see during a vacancy, and the election of a bishop to supply it. There are even some chapters exempt from the jurisdiction of the bishop, and owning no head but their dean. From the example of cathedral chapters, collegiate ones also continued to form bodies after they had abandoned living in community.

Canons are of various kinds; as,

Cardinal Canons, who were those attached, and, as the Latins call it, *incardinati*, to a church, as a priest is to a parish.

Domicellary Canons, young canons, who, not being in orders, had no right in any particular chapters.

Expectative Canons, or such as, without having any revenue or prebend, had the title and dignities of canons, a voice in the chapter, and a place in the choir, till such time as a prebend should become vacant.

Foreign Canons, or such as did not officiate in the canonries to which they belonged. To these were opposed mansionary canons, or canons residentiary.

Lay or *Honorary Canons*, who are those among the laity who have been admitted, out of honour and respect, into some chapter of canons.

Regular Canons, who are canons that still live in community, and, like religious, have in process of time added the solemn profession of vows to the practice of their rules. They are called regulars, to distinguish them from those secular canons who abandon living in community, and at the same time the observance of the canons made as the rule of the clergy for the maintenance of the ancient discipline. The canons subsisted in their simplicity till the eleventh or twelfth century, when some of them, separating from the community, took with them the name of canons, or acephalous priests, because they declined to live in community with the bishop; and those who were left thenceforth acquired the denomination of canons regular, and adopted most of the professions of the rule of St Augustin. This order of regular canons of St Augustin was brought into England by Adelwald, confessor to Henry I., who erected a priory at Nostel in Yorkshire, and obtained for them the church of Carlisle as an episcopal see, with the privilege of choosing their own bishop. They were singularly protected and encouraged by Henry I., who gave them the priory of Dunstable in 1107; and by Queen Maud, who, in the following year, gave them the priory of the Holy Trinity in London. It appears that under the reign of Edward I. they had fifty-three priories.

Tertiary Canons, or those who had only the third part of the revenues of the canonicate.

CANON, in an ecclesiastical sense, is a law or rule, either of doctrine or discipline, enacted especially by a council, and confirmed by the authority of the sovereign.

Canons are properly decisions of matters of religion; or regulations of the policy and discipline of a church, made by

Canon. councils, either general, national, or provincial. Such are the canons of the councils of Nice, Trent, &c.

There have been various collections of the canons of the eastern councils; but there are four principal ones, each ampler than the preceding. The first, according to Usher, A.D. 380, containing only those of the first ecumenical council, and the first provincial ones; they were only 164 in number. To these, Dionysius Exiguus, in the year 520, added the fifty canons of the apostles, and those of the other general councils. The Greek canons in this second collection end with those of the council of Chalcedon; to which are subjoined those of the council of Sardica, and the African councils. The fourth and last collection comes down as low as the second council of Nice; and it is on this that Balsamon and Zonaras have commented.

Apostolical Canons are those which have been usually ascribed to St Clement. Bellarmin, Baronius, and others, will have them to be genuine canons of the apostles. Catelerius observes that they cannot be ascribed to the apostles or Clement, because they are not received with other books of Scripture, are not quoted by the writers of the first ages, and contain many things not agreeable to the apostolical times. Hincmar, de Marca, Beveridge, and others, believe them to have been framed by the bishops who were the apostles' disciples in the second or third century; S. Basnage is of opinion that they were collected by an anonymous writer in the fifth century, but Daille and others maintain them to have been forged by some heretic in the sixth century; and S. Basnage conjectures that some of them are ancient, and others not older than the seventh century. The Greek Church allows eighty-five of them, and the Latin only fifty; though there are eight-four in the edition given of them in the Corpus Juris Canonici.

CANON, signifying in *Scripture* a rule to walk by, or standard to judge by, was by the early Christians appropriated as a distinctive appellation of the inspired Scriptures, because they regarded them as the only rule of faith and practice. For the formation of the Canon, see BIBLE.

Paschal CANON, a table of the moveable feasts, showing the day of Easter, and the other feasts depending on it, for a cycle of nineteen years.

CANON, in monastic orders, a book in which the religious of every convent have a fair transcript of the rules of their order frequently read among them as their local statutes. This is also called *regula*, as containing the rule and institution of their order. The canon differs from the *missale*, *martyrologium*, and *necrologium*.

CANON, again, is used for the catalogue of saints acknowledged and canonized in the Romish Church.

CANON is also used, by way of excellence, in the Romish Church, for the secret words of the mass, from the preface to the *Pater;* in the middle of which the priest consecrates the host. The common opinion is, that the canon of the mass commences with *Te igitur*, &c.

CANON, in the ancient music, is a rule or mode of determining the intervals of notes. Ptolemy, rejecting the Aristoxenian way of measuring the intervals in music, by the magnitude of a tone, which was supposed to be formed by the difference between a diapente and a diatessaron, thought that musical intervals should be distinguished according to the ratios or proportions which the sounds terminating those intervals bear to one another, when considered according to their degree of acuteness or gravity, which, before Aristoxenus, was the old Pythagorean way. He therefore made the diapason consist in a double ratio, the diapente in a sesquialterate, the diatessaron in a sesquitertian, and the tone itself in a sesquioctave, and all the other intervals according to the proportion of the sounds that terminate them; wherefore taking the canon, as it is called, for a determinate line of any length, he shows how this canon is to be cut accordingly, so that it may represent the respective intervals; and this method answers exactly to experiment, in the different lengths of musical chords. From this canon Ptolemy and his followers have been called *Canonici*, as those of Aristoxenus were called *Musici*.

Canon Law. CANON LAW is a term used to denote the ecclesiastical law sanctioned by the church of Rome, and possessing more or less direct influence in all countries which acknowledge the authority of the pope. The word κανων signifies a rule, and this word was not at first considered as too feeble to express the claims of the church to the obedience of her children; but, in the progress of priestly usurpation, the successor of St Peter began to arrogate a more ample and definite jurisdiction, and to extend his regulations to many causes which are not strictly ecclesiastical. The stupendous fabric of papal dominion attained its full height in the eleventh century, under the auspices of Hildebrand, who was elected in the year 1073, and assumed the name of Gregory VII. It was one of his dictates, that the church of Rome has never erred, and, according to the testimony of Scripture, never shall err;[1] and after this maxim was fully admitted, nothing remained to obstruct the progress of spiritual arrogance. What had formerly been described as a *rule*, was now dignified with the name of *law;* and from this period, a period of the deepest ignorance and superstition, the canon law obtained great influence in most countries of Europe. After the foundation of those seminaries of learning which we denominate universities, it acquired a distinguished place among the other faculties; and a knowledge of the canon law became a common road to the highest honours. It is a maxim of the commentators, that a Doctor of the Canon Law is to be preferred to a Doctor of Divinity in such dioceses as do not contain many heretics.[2]

The canon law is derived from many different sources. The authority of the Scriptures cannot be entirely disregarded; but the writings of the fathers and doctors of the church, the decrees of councils, and the decretals of popes, are much better adapted to the general views of the canonists. The canon is to a great extent to be considered as the spurious offspring of the civil law: what is most valuable it has derived from the Roman jurisprudence; and its own peculiar maxims and rules have all the same general tendency towards the power and aggrandizement of churchmen.

The Greek church has bequeathed various reliques, which cannot be safely neglected by those who investigate the history of the canon law, as well as the general history of the church. Its *Codex Canonum*[3] is confirmed by the 131 Novel of Justinian, and is therefore considered as a portion of the civil law. From this collection the emperor borrowed those ecclesiastical constitutions which occur in the Code and Novels. We cannot however pursue this branch of enquiry, but shall merely direct the reader's attention to two very elaborate publications. The first of these is the "Bibliotheca Juris Canonici veteris: ex antiquis codicibus MSS. bibliothecæ Christophori Justelli, opera et studio Gulielmi Voelli et Henrici Justelli." Lu-

[1] Mastricht Historia Juris Ecclesiastici et Pontificii, p. 297. Amst. 1686, 8vo.
[2] Lancelotti Institutiones Juris Canonici. tom. i. p. 232. edit. Doujat. Paris. 1685, 2 tom. 12mo.
[3] Codex Canonum Ecclesiæ universæ, a Justiniano confirmatus. Christophorus Justellus, J. C. nunc primum restituit, ex Græcis codicibus editis et MSS. collegit et emendavit, Latinum fecit, et notis illustravit. Paris. 1610, 8vo.

tetiæ Paris. 1661, 2 tom. fol. For the other we are indebted to Dr Beveridge, the very learned bishop of St Asaph: " Συνοδικον, sive Pandectæ Canonum SS. Apostolorum, et Conciliorum ab Ecclesia Græca receptorum; nec non canonicarum SS. Patrum Epistolarum: una cum scholiis antiquorum singulis eorum annexis, et scriptis aliis huc spectantibus." Oxonii, 1672, 2 tom. fol. This publication was followed by his " Codex Canonum Ecclesiæ primitivæ vindicatus et illustratus." Lond. 1678, 4to. Nor must we here neglect to mention a very recent work by Professor Biener of Berlin: " De Collectionibus Canonum Ecclesiæ Græcæ Schediasma litterarium." Berolini, 1827, 8vo.

Of the rules or laws received by the Latin church, there were many ancient collections. Dionysius Exiguus, an abbot who flourished about the beginning of the sixth century, formed two different compilations, one of the canons of the church, another of the decretals of the bishop of Rome; and this was the earliest collection of decretals. These were followed by the collections of Fulgentius Ferrandus, who flourished soon afterwards; of Isidorus Hispalensis, who was bishop of Seville from 595 to 636; of Cresconius, who flourished about the year 690; of Isidorus Mercator, otherwise called Peccator, who wrote about the year 800, and is described as " impostor nequissimus;" and of various other compilers, whose labours we have not at present an opportunity of reviewing. Burchardus, who was bishop of Worms from 996 to 1025, formed a compilation of the canon law, described as " Magnum Decretorum Volumen," and divided into twenty books. Ivo Carnotensis, bishop of Chartres from 1092 to 1115, was the author of a similar compilation, which bears the title of *Decretum;* and to him is ascribed another work on the canon law, sometimes called *Pannomia,* and sometimes *Pannormia.* Both these works have been repeatedly printed.

Ivo was followed by Gratian, whose *Decretum* forms the first and most ample part of the *Corpus Juris Canonici.* He was a native of Clusium, or Chiusi, near Florence, and, according to a very improbable account, was the brother of Petrus Lombardus and Petrus Comestor. One of these three individuals was a native of Tuscany, another, as his name denotes, of Lombardy, and the third of France; but, in order to remove the difficulty which arises from this variety in the places of their nativity, some writers do their mother the honour of supposing that her three distinguished sons were the fruit of her unlawful intercourse with three different fathers, at different periods, and in different places. Gratian was a Benedictine monk of the monastery of St Felix and St Nabor at Bologna. His work has long been commonly known by the title of *Decretum,* but is more correctly described as " Decretorum Collectanea;" and it is remarked by the very learned archbishop of Tarragona, that the old manuscripts scarcely ever bear the former title, but generally that of " Concordia discordantium Canonum."[1] According to the usual account, it was compiled in the year 1151: this may indeed have been the period of its completion, but it evidently was not the labour of a single year. Cardinal Bellarmin has endeavoured to reconcile two conflicting authorities, by supposing that Gratian commenced his work in 1127, and completed it in 1151, thus allowing a period of twenty-four years for its composition.[2] The Decretum was presented to his holiness Eugenius III., who is said to have testified his approbation by conferring upon him the bishopric of Chiusi.[3] It never obtained the formal sanction of the pope; but although it is thus to be regarded as the work of a private individual, it speedily secured, and has ever since maintained, a degree of authority which makes a near approach to that which belongs to written law.[4] The principal sources from which his compilation is derived, are the sacred Scriptures, the spurious work described as the Apostolical Canons, the decisions of ecumenical and local councils, the decretal epistles, partly genuine and partly spurious, of seventy-eight Roman pontiffs, the works of the Greek and Latin fathers and other ecclesiastical writers, the Theodosian Code and the *Corpus Juris Civilis,* the capitularies of kings of France and the rescripts of emperors. It is divided into three parts; of which the first and third are subdivided into distinctions, and the second into causes and questions.[5] Gratian, who wrote in an unenlightened age, is chargeable with many errors of ignorance or inadvertence, which the canonists have not scrupled to detect and expose. Augustinus has composed a series of dialogues *De Emendatione Gratiani,* in which the reader will find much learned and curious disquisition; and many other writers, editors as well as commentators, have endeavoured to rectify errors and supply defects. " To the compilations of Isidore and Gratian," says a catholic lawyer, " one of the greatest misfortunes of the church, the claim of the popes to temporal power by divine right, may in some measure be attributed. That a claim so unfounded and so impious, so detrimental to religion, and so hostile to the peace of the world, should have been made, is strange—stranger yet is the success it met with."[6]

The second collection which appears in the body of the canon law is entitled *Decretalium D. Gregorii Papæ IX. Compilatio.* It was formed under the direction and authority of this pontiff, who filled the chair of St Peter from 1227 to 1241. He is himself commended for his skill in jurisprudence, and in the execution of this plan he employed Raymundus de Penyafort, a learned Spaniard, who was afterwards enrolled in the catalogue of saints.[7] The work is divided into five books, and each book into various titles. " Epistolæ decretales" are rescripts of the popes, in answer to prelates or other individuals by whom they have been consulted. They are sometimes called Decretalia, but commonly Decretales, the words Rescripta and Epistolæ being respectively understood. The work however is not strictly conformable to its title; for although the greater part of it is composed of decretals, the compiler has had recourse to various other authorities.

Gregory's decretals are followed by *Liber sextus Decretalium D. Bonifacii Papæ VIII:* which, notwithstanding the general title, is divided into five books. It was intended as supplementary to the other collection, and was compiled under the authority of Boniface, whose pontificate extended from 1294 to 1303. Besides the decretals of Boniface himself, and of preceding popes, ascending

7 Antonii Bibliotheca Hispana vetus, tom. ii. p. 67. edit. Bayerii.

to Gregory IX., it includes decrees of the two general councils held at Lyons in 1245 and 1274.

The next work in the series bears the title of *Constitutiones Clementis Papæ V. in Concilio Vienensi editæ,* and is likewise divided into five books. Clement, whose residence was at Avignon, presided in the council of Vienne in the year 1312; and in addition to the constitutions there enacted, his collection comprehends some other constitutions and decretals which he himself divulged before or after the holding of that council. After his death, these *Clementinæ* were promulgated in the year 1317 by his successor John the Twenty-first, otherwise called John the Twenty-second.

Of the same pope, who likewise resided at Avignon, there is a collection of twenty consitutions, which bear the name of *Extravagantes Joannis XXII.* They were so called, because for some time they wandered beyond the limits of the collection which contained the works already enumerated as belonging to the body of the canon law. The next work, which is entitled *Extravagantes Communes,* and is divided into five books, comprehends the constitutions of various popes, concluding with Sixtus IV. whose pontificate extended from 1471 to 1484.

These are all the different compilations which constitute what is denominated the body of the canon law. It may be proper to add that the best edition bears this title: "Corpus Juris Canonici, Gregorii XIII. Pont. Max. jussu editum: a Petro Pithœo et Francisco fratre, Jurisconsultis, ad veteres codices manuscriptos restitutum, et notis illustratum." Parisiis, 1687, 2 tom. fol. Of a more recent as well as more early date, there are many other editions which we cannot here enumerate; and we shall only mention another, which was published by a protestant professor: "Corpus Juris Canonici: Justus Henningius Boehmer, J. C. recensuit, cum codicibus veteribus manuscriptis aliisque editionibus contulit, variantes lectiones adjecit, notis illustravit." Halæ Magdeburg. 1747, 2 tom. 4to.

The Institutes of Jo. Paulus Lancelottus, divided into four books, are inserted in different editions of the Corpus; and this circumstance has led some individuals, superficially acquainted with the subject, to suppose that they form an essential part of the authorized collection. They are however the production of a private lawyer, and having never received the sanction of the pope, they possess no authority beyond that which belongs to the character of the author as an able interpreter of the canon law. This work was undertaken with the approbation of Paul IV.: fifteen years elapsed before its completion; and Lancelottus, having at length submitted it to the papal censors, and lingered two years in Rome, was compelled to abandon the hope of obtaining the sanction of his holiness Pius IV. The book was published in 1563, a few months before the dissolution of the council of Trent. The only favour which the author could obtain was that his Institutes might be added to the Corpus, but without any confirmation of their authority. They are sometimes inserted, and sometimes omitted; nor do they occur in that edition which we have already mentioned as the best. As they do not include the changes and modifications introduced by the council of Trent, they require the aid of a perpetual commentary. The Institutes of Lancelottus are closely modelled upon those of Justinian. His subject does not easily admit of any high degree of classical purity, but the work is at least written with much neatness and perspicuity. The notes of Doujat form a very important addition: they evidently proceed from a man of ability and learning, and are generally composed in a style of pregnant brevity.

The subsequent progress of the canon law, together with the more recent method of expounding it, must be learned from other writers. The most distinguished canonist of the last century was Dr Van Espen, professor of the canon law in the university of Louvain, whose works extend to five volumes in folio. His *Jus Ecclesiasticum universum* Mr Butler has described as "a work which, for depth and extent of research, clearness of method, and perspicuity of style, equals any work of jurisprudence which has issued from the press; but which, in some places, where the author's dreary Jansenism prevails, must be read with disgust."[1] The life of the learned and conscientious author, it may be proper to state, has been elaborately written by Bellegarde."[2] There are other two recent works on the canon law which we must recommend to the student's notice. "Caroli Sebastiani Berardi Commentaria in Jus Ecclesiasticum universum." Venetiis, 1789, 4 tom. 4to. "Joannis Devoti Institutionum Canonicarum libri IV." Florentiæ, 1816–7, 4 tom. 8vo. Neither of these is the earliest edition. Those who have any wish to ascertain how the canon law is now taught by the catholics of Germany, may consult the following works. "Mauri de Schenkl Institutiones Juris Ecclesiastici communis: editio emendata et valde adaucta a Josepho Scheill." Landishuti in Bavaria, 1830, 2 tom. 8vo. "Fundamenta Juris Ecclesiastici Catholicorum: in usus scholasticos conscripsit Jos. Anton. Sauter." Rotwilæ, 1825–6, 2 tom. 8vo. The canon law was ably illustrated by some of the German protestants, particularly by Ziegler, Thomasius, and Böhmer. Such was the reputation enjoyed by the last of these individuals, that difficult and intricate processes were frequently transmitted from Italy, to be decided by the law-faculty of the university of Halle, during the period when Bohmer was dean. Nor is this study neglected by the protestants of our own age. Dr Walter, professor of law in the university of Bonn, is the author of a work, published for the fourth time, under the title of "Lehrbuch des Kirchenrechts aller Christlichen Confessionen." Bonn, 1829, 8vo. And a similar work has more recently been published by Eichhorn of Göttingen, well known for his history of the German law.

While the papal power was yet in its meridian height, this system of jurisprudence could only claim the proper force of law within the papal dominions. It maintained a very powerful and direct influence in every other country which acknowledged the bishop of Rome's supremacy; but its dictates were controlled by the legislative authority, and modified by the practice of the courts, in each of the countries where it found admission. Thus the canon law of France differed in many respects from that of Spain, and the canon law of England from that of Austria. "All the strength," says Sir Matthew Hale, "that either the papal or imperial laws have obtained in this kingdom, is only because they have been received and admitted either by the consent of parliament, and so are part of the statute laws of the kingdom, or else by immemorial usage and custom in some particular cases in courts, and no otherwise, and therefore so far as such laws are received and allowed here, so far they obtain, and no further; and the authority and force they have here is not founded on, or derived from themselves; for so they bind no more with us than our laws bind in Rome or Italy."[3] These remarks, written in protestant times, were equally applicable during the times of popery.

[3] Hale's Hist. of the Common Law of England, p. 27.

The influence of the canon law in countries which have long abjured the authority of the pope, renders it even there a study of occasional importance to lawyers. "So deep," says Lord Stair, "hath this canon law been rooted, that even where the pope's authority is rejected, yet consideration must be had to these laws, not only as those by which church benefices have been erected and ordered, but as likewise containing many equitable and profitable laws, which, because of their weighty matter, and their being once received, may more fitly be retained than rejected."[1] We cannot refrain from adding, that some knowledge of the canon law, at least of its history and external form, is of no small consequence to those who wish to understand the history and literature of the middle ages. This remark we shall endeavour to confirm by one or two examples. Winton, the venerable prior of Lochleven, after having mentioned the irregular manner in which Walter Danielstoun took possession of the see of St Andrews, subjoins this observation:

Yeit be this electioune
He dyd all ministratioune
In jurisdictioune spirituale,
And in all thingis temporale,
All that quhile, rycht as he
Had had lauchful autorite,
Pretendand ay for his resown
Nichil de electione.[2]

This passage, which to most readers must appear sufficiently obscure, the very accurate and intelligent editor, Macpherson, has left without explanation or conjecture. It bears an allusion to the *Decretales Gregorii IX.* lib. i. tit. vi. cap. xliv. § 2. *Nihil* is the first word of the chapter, and *de electione* denotes the subject of the title, or subdivision of the book. Danielstoun, whose election had not been confirmed by the pope, evidently relied on the authority of the subsequent passage: "Ita quod interim valde remoti, videlicet ultra Italiam constituti, si electi fuerint in concordia, dispensative propter necessitates ecclesiarum et utilitates, in spiritualibus et temporalibus administrent, sic tamen ut de rebus ecclesiasticis nihil penitus alienent."

Sir David Lindsay, another Scottish poet, makes the following allusion to the inordinate pretensions of the pope.

His style at lenth gif thow wald knaw,
Thow moste ga luke the cannon law:
Baith in the Sext and Clementene
His staitlie style thair may be sene.[3]

His editor, Mr George Chalmers, who was guilty of a radical error when he supposed himself to be a man of learning, has subjoined this curious annotation. "The allusion is to the works of Pomponius Sextus, the great jurist of the third century." It is first to be remarked that Pomponius did not flourish in the third, but in the second century;[4] but if this "great jurist," of whom he speaks so familiarly, had actually written in the third century, how could he have illustrated the temporal power and splendour of the pope before Christianity was established in the Roman empire? Manifestly the *Sext* to which Lindsay refers is the "Liber *sextus* Decretalium;" and the other authority the *Clementinæ*, or constitutions of Clement V. (D. I.)

CANONESS, in the Romish Church, a woman who enjoys a prebend, affixed by the foundation to maids without obliging them to renounce the world, or make any vows.

CANONICA, an appellation given by Epicurus to his doctrine of logic. It was called *canonica*, as consisting of a few canons or rules for directing the understanding in the pursuit and knowledge of truth. The *canonica* of Epicurus is represented as a very slight and insufficient logic by several of the ancients, who put a great value on his ethics and physics. Laertius even assures us that the Epicureans rejected logic as a superfluous science; and Plutarch complains that Epicurus made an unskilful and preposterous use of syllogisms. But these censures seem too severe. Epicurus was not averse to the study of logic, but even gave better rules in this art than those philosophers who aimed at no glory but that of being thought logicians. He only seems to have rejected the dialectics of the Stoics, as full of vain subtilties and deceits, and fitted rather for parade and disputation than real use. The stress of Epicurus's *canonica* consists in his doctrine of the criteria of truth. All questions in philosophy are either concerning words or things: concerning things, we seek their truth; concerning words, their signification: things are either natural or moral; and the former are either perceived by sense or by the understanding. Hence, according to Epicurus, arise three criteria of truth, namely, sense, anticipation or prænotion, and passion. The great canon or principle of Epicurus's logic is, that the senses are never deceived; and therefore, that every sensation or perception of an appearance is true.

CANONICAL, something that belongs to, or partakes of, the nature of a rule or canon.

Canonical *Hours* are certain stated times of the day, consigned, more especially by the Romish Church, to the offices of prayer and devotion. Such are *matins*, *lauds*, *sixth* and *ninth vespers*. In our country the canonical hours are from eight to twelve in the forenoon, before or after which marriage cannot be legally performed in any parish church.

Canonical *Obedience* is that submission which, by the ecclesiastical laws, the inferior clergy are bound to pay to their bishops, and other religious orders to their superiors.

Canonical *Sins*, in the ancient church, those which were deemed capital or mortal. Such especially were idolatry, murder, adultery, heresy, and schism.

Canonical *Punishments* are such as the church may inflict; as excommunication, degradation, and penance, &c.

Canonical *Life*, the method or rule of living prescribed by the ancient clergy who lived in community. It was a kind of medium between the monastic and the clerical. Originally the orders of monks and clerks were entirely distinct; but in process of time pious persons instituted colleges of priests and canons, where clerks brought up for the ministry, as well as others already engaged therein, might live under a fixed rule. This was called the *canonical life*, and those who embraced it *canons*. Authors are divided about the founder of the canonical life. Some maintain that it was founded by the apostles; others ascribe it to Pope Urban I. (about 1230), who is said to have ordered bishops to provide such of their clergy as were willing to live in community with necessaries out of the revenues of their churches. It is generally attributed to St Augustin, who instituted a monastery within the episcopal palace. According to Onuphrius Panvinus, Pope Gelasius I., about A.D. 495, placed the first regular canons of St Augustin in the Lateran church.

Canonical *Letters*, in the ancient church, were a sort of testimonials of the orthodox faith, which passed between the bishops and clergy, to keep up the Catholic communion, and distinguish orthodox Christians from Arians and other heretics.

CANONICUM, in the Greek church, a fee paid by the clergy to bishops, archbishops, and metropolitans, for degrees and promotions. Also a due of first fruits paid by the laity to their bishops or priests.

CANONIST, a professor of canon law. Canonists and civilians are usually combined in the same persons; hence the title of *juris utriusque doctor*, or *legum doctor*, expressed in abbreviature, J.U.D. or LL.D.

CANONIZATION, a ceremony in the Romish Church, by which persons deceased are ranked in the catalogue of the saints. This act is preceded by beatification; and after the merits of the individual have been duly tested and approved, the pope decrees the canonization.

The term was not introduced till the twelfth century. The first person who availed himself of it was Udalric, bishop of Constance, in his letter to Pope Calixtus II. relative to the canonization of Bishop Conrad. The act, however, dates from a much more remote antiquity. The ceremony was originally only a commemoration of the martyrs, whose assistance was invoked in the name of the church militant to which they had belonged. Originally bishops decided whether or not the candidate had fairly vindicated his claim to the honour; but they only acted as the organ of public opinion. As soon as the power of Rome was once more upon the ascendant in Europe, the popes naturally appropriated to themselves the important privilege of canonization. None but martyrs were at first admitted into the category of saints, but in course of time the privilege was extended to some of those pious men who, without having sealed their testimony with their blood, had evinced the sincerity of their belief by the purity of their practice. In later times, however, the pope assumed the right of admitting into the sacred catalogue such potentates as had favoured his temporal interests. Notable instances of this are the names of Henry, Emperor of Germany, canonized by Eugene III., and Edward the Confessor, of England, canonized by Alexander III.

So long as the right of according the honours of canonization was vested in the bishops, there was no public guarantee that it had been exercised with rigour or discretion. But when it passed into the hands of the popes, means were taken to prevent any but really meritorious persons from being enrolled in the holy category. Even then, however, a very simple ordeal sufficed. A few pretended miracles happening at a tomb were enough to give its inmate a claim to have his name inscribed in the canon of the mass among the number of the happy. If the honour were conferred on any saint shortly after his death, it was commonly through family interest, or the intrigues of noble relatives. At a later period, when the ceremony was only performed after a considerable lapse of time, reasons were always hard to be found why the saintly candidate should be rejected. In modern times the court of Rome has shown itself extremely averse to promiscuous canonization; and since the days of Benedict XIV., the *advocatus diaboli*, or devil's advocate, has exercised extreme severity in sifting the claims of aspirants. It is further necessary that a period of a hundred years should elapse between the death of the saint and his admission into the calendar. But the more pious men of every country in Europe have of late evinced so little ambition to secure this posthumous compliment, that it may now be considered to have gone fairly out of fashion. Chemical science moreover has within the last century wrought so many miracles, that those of the church have fallen into neglect, if not absolute contempt.

On the day of canonization the pope and cardinals officiate in white; while St Peter's church is illuminated and hung with rich tapestry, upon which the arms of the pope, and of the prince or state requiring the canonization, are embroidered in gold and silver.

CANONRY, the benefice filled by a canon. It differs from a prebend, in that the prebend may subsist without the canonicate, whereas the canonicate is inseparable from the prebend; again, the right of suffrages, and other privileges, are annexed to the canonicate, and not to the prebend.

CANOPUS, a star of the first magnitude, in the rudder of the constellation Argo.

Canōpus, or *Canōbus*, a deity of the ancient Egyptians, and, according to some, the god of water. It is said that the Chaldeans, who worshipped fire, carried their idol through other countries to try its powers. It easily subdued the gods of wood, stone, brass, silver, and gold, and therefore its priests declared that all gods did it homage. But when the Chaldeans brought their god to contend with Canōpus, the priest took a large earthen jar, and bored in it several holes, which he stopped with wax; and then, after painting the vessel of various colours and filling it with water, he fitted the head of an idol to it. The Chaldeans then kindled their fire around the image; but it was speedily extinguished, for the wax melted and the water gushed out. Thus was the god of the Chaldeans vanquished by Canōpus. Jars similar to that we have just noticed are of frequent occurrence on the Egyptian monuments. They are generally ornamented with images and hieroglyphics, and surmounted by the head of some animal or by a human head. They are also found on coins. It is uncertain, however, whether a jar deity was really worshipped at Canōbus. These jars were probably merely symbolical representations of certain divinities, or perhaps of the god Serapis, who was the chief deity of Canōbus.

Canōpus, or *Canōbus*, the pilot of Menelaus, who, on his return from Troy, died in Egypt of the bite of a serpent. A temple was erected in his honour at Canōpus, which derived its name from him.

Canōpus, or *Canōbus*, in *Ancient Geography*, a town of Lower Egypt, on the Mediterranean, a hundred and twenty stadia, or fifteen miles, to the east of Alexandria.

CANOPY, in *Architecture*, a magnificent kind of decoration, serving as a hood or cover above an altar, throne, tribunal, pulpit, &c. The word is formed from κωνωπειον, *a net spread over a bed to keep off the gnats*, from κώνωψ, *a gnat*.

Canopies are also borne over the head in processions. The canopy of an altar is more peculiarly called *ciborium*.

CANOSA. See Canusium.

CANOVA, Antonio, one of the greatest sculptors of modern times, was born on the 1st of November 1757, at Passagno, an obscure village situated amid the recesses of the hills of Asolano, where these form the last undulations of the Venetian Alps, as they subside into the plains of Treviso. At three years of age Canova was deprived of both parents. Their loss, however, was compensated by the tender solicitude and care of his grandfather and grandmother, the latter of whom lived to experience in her turn the kindest personal attention from her grandson, who, when the efforts of successful genius had afforded him the means, gave her an asylum in his house at Rome. The father and grandfather of our artist followed the occupation of stone-cutters; and it is said that their family had for several ages supplied Passagno with members of that profession. As soon as Canova's hand could hold a pencil, he was initiated into the principles of drawing by his affectionate grandfather Pasino, who was acquainted with the subject. He also possessed some knowledge of architecture, designed well, and showed considerable taste in the execution of ornamental works. To his art he was attached with fond partiality; and upon his young charge he looked as one who was designed not only to perpetuate the family name, but also the family profession. The object of his hopes and instructions may be said to have done so; but his works were destined to be known far beyond the period of his life, or the circle of his native hills.

The early years of Canova were passed in study. The

bias of his mind was to sculpture, and the facilities afforded for the gratification of this predilection in the workshop of his grandfather were eagerly improved. In his ninth year he executed two small shrines of Carrara marble, which are still extant. Soon after this period he appears to have been constantly employed under his grandfather. Amongst those who patronized the old man was the patrician family Faliero of Venice, and by this means young Canova was first introduced to the senator of that name, who afterwards became his most zealous patron. Between the younger son, Giuseppe Faliero, and the artist, a friendship commenced, which terminated only with life. From the interest which was excited in this family for Canova, Signor Faliero was induced to receive him under his immediate protection. It has been related by an Italian writer, and since repeated by several biographers, that Canova was indebted to a fortuitous circumstance, the moulding of a lion in butter, for the warm interest which the senator took in his welfare. The anecdote may be true; but it does not appear to rest on authority sufficiently strong to warrant our stating it as authentic. By his kind patron Canova was placed under Bernardi, or, as he is generally called by filiation, Toretto, a sculptor of considerable eminence, who had taken up a temporary residence at Pagnano, a village in the vicinity of the senator's mansion. This took place whilst he was in his thirteenth year; and with Toretto he continued about two years, making in many respects considerable progress. This master returned to Venice, where he soon afterwards died; but by the high terms in which he spoke of his pupil to Faliero, the latter was induced to bring the young artist to Venice, where he accordingly went, and was placed under a nephew of Toretto. With this master he continued about a year, studying with the utmost assiduity. After the termination of this engagement he began to work on his own account, and received from his patron an order for a group on the subject of Orpheus and Eurydice. The first figure, which represents Eurydice in flames and smoke in the act of leaving the infernal realms, was completed towards the close of his sixteenth year. It was highly esteemed by his patron and friends, and the artist was now considered as qualified to appear before a public tribunal. The kindness of some monks supplied him with his first work-shop, which was the vacant cell of a monastery. Here for nearly four years he laboured with the greatest perseverance and industry. He was also regular in his attendance at the academy, where he carried off several prizes. But he did not confine himself to these exercises alone. He resolved to begin where the art itself began, in the study and imitation of nature. From his contemporaries he could learn nothing, for their style was vicious. From their works, therefore, he reverted to living models, as exhibited in every variety of situation. A large portion of his time was also devoted to anatomy, which science was regarded by him as " the secret of the art." He also frequented places of public amusement, where he carefully studied the expressions and attitudes of the performers. Not a day was allowed to pass without his making some visible advances in his profession. He formed a resolution, which was faithfully adhered to for several years, never to close his eyes without producing some design. Whatever was likely to forward his advancement in sculpture, he studied with ardour. On archaiological pursuits he bestowed considerable attention. With ancient and modern history he rendered himself well acquainted, and he also began to acquire several of the continental languages. When we view such industry, inspired and directed by such a genius as that of Canova, it scarcely appears matter of wonder that the result should be a new era in the art.

Three years had now elapsed without any production coming from his chisel. He began, therefore, to complete the group for his patron, and the Orpheus which followed evinced the great advances he had made in his profession. The work was universally applauded, and laid the foundation of his fame. Several groups succeeded this performance, amongst which was that of Dædalus and Icarus, the most celebrated work of his noviciate. The simplicity of style and the faithful imitation of nature which characterized them called forth the warmest admiration. But there was still wanting in his productions that elevation and ideal beauty which he afterwards attained to, and which rather carried nature to its highest perfection than went beyond it. His merits and reputation being now generally recognised, he began to turn his attention from the shores of the Adriatic to the more classic banks of the Tiber, for which he set out at the commencement of his twenty-third year.

Previous to his departure for Rome, his friends had applied to the Venetian senate for a pension, to enable him without embarrassment to pursue his studies. The application was ultimately successful. It amounted to three hundred ducats, about sixty pounds per annum, and was limited to three years. Our artist had obtained letters of introduction to the Venetian ambassador, the Cavaliere Zuliani, an enlightened and generous protector of the arts, and was received in the most gracious and hospitable manner. Canova's arrival in the " eternal city" marks a new era in his life. It was here he was to perfect himself, by a study of the most splendid relics of antiquity, and to put his talents to the severest test by a competition with the greatest living masters of the art. The result was equal to the highest hopes cherished either by himself or by his friends. The work which first established his fame at Rome was Theseus vanquishing the Minotaur. The figures are of the heroic size, that is, larger than life. The victorious Theseus is represented as seated on the lifeless body of the monster. The exhaustion which visibly pervades his whole frame proves the terrible nature of the conflict in which he had been engaged, while at the same time it evinces the genius of the sculptor. Simplicity and purity of natural expression had hitherto characterized his style; but with these were now united more exalted conceptions of grandeur and of truth. By those who were capable of appreciating the beauties of the Theseus, it was regarded with rapturous enthusiasm, as worthy of the best days of sculpture in a land where sculpture was unrivalled; and it formed a noble presage of future glory and yet more splendid achievements.

His next undertaking was a monument in honour of Clement XIV.; but before he proceeded with it, he deemed it necessary to request permission from the Venetian senate, whose servant he considered himself to be, in consideration of the pension. This he solicited in person, and it was granted in the most handsome manner. He returned immediately to Rome, and opened that studio in the Strada Babbuino, which was soon to be one of the proudest boasts of Italy, and to which the ardent devotees of the art from every nation of Europe were to perform pilgrimage. He spent about two years of unremitting toil in arranging the design and composing the models for the tomb of the pontiff. After these were completed, other two years were employed in finishing the monument, and it was finally opened to public inspection in 1787. Expectation had been highly excited, and never was it more amply gratified. The work, in the opinion of the best judges, stamped the author as the first artist of modern times. After five years of incessant labour, he completed another cenotaph to the memory of Clement XIII. of which it is sufficient praise to say, that it raised still higher the fame of

the author. Works came now so rapidly from his chisel, that it will be impossible to enumerate any but the most conspicuous. Amongst those which belong to the period in question is Psyche with a butterfly, which is placed on the left hand, and held by the wings with the right. This beautiful figure, which is intended as a personification of man's immaterial part, is considered as in almost every respect the most faultless and classical of Canova's works. In two different groups, and with opposite expression, the sculptor has represented Cupid with his bride; in the one they are standing, in the other recumbent, and both are of superlative excellence. These and other proofs of lofty genius raised his reputation so high, that the most flattering offers were sent him from the Russian court to induce him to remove to St Petersburg; but these were declined. "Italy," says he, in writing of the occurrence to a friend, "Italy is my country—is the country and native soil of the arts. I cannot leave it; my infancy was nurtured here, and if my poor talents can be useful in any other, they must be of some utility to this; and ought not hers to be preferred to all others?" Genius never appears so truly great as when it is united with a disinterested love of country. In this respect Canova will ever command admiration. The powers of his mind scarcely surpassed the virtues of his heart.

Numerous works were produced during the years 1795-6-7, of which several were repetitions of previous productions. It is only necessary to notice the celebrated group representing the parting of Venus and Adonis. The youth is gazing tenderly upon the goddess. With his left arm he encircles her waist, while his right grasps a hunting spear. She, on the other hand, by the most endearing yet chaste caresses, endeavours to avert his resolution of departing. This famous production was sent to Naples; and, out of respect to the artist, the king ordered every tax which attended its importation to be remitted. As a more substantial mark of approbation, he decorated the sculptor with the insignia of the order of the Two Sicilies. The French revolution was now extending its ravages over Italy; and the pure and peaceful spirit of Canova, shrinking from scenes of contention and blood, sought obscurity and repose in the bosom of his native Passagno. Thither he retired in 1798, and continued about a year, principally employed in the sister art of painting, in which also he was no ordinary proficient. One of his productions in this department of art is a picture representing the dead body of the Saviour just removed from the cross, surrounded by the three Marys, the beloved disciple, Joseph of Arimathea, and, somewhat in the back ground, Nicodemus. Above appears the personification of the Father, with the mystic dove in the centre of a glory, and surrounded by a circle of cherubs. This admirable composition, which was greatly applauded, he presented to the parochial church of his native place. Events in the political world having come to a temporary crisis, he returned to Rome; but his health, from arduous application, having been impaired, he took a journey through a part of Germany, in company with his friend Prince Rezzonica. He returned from his travels much improved, and again commenced his labours with renewed vigour and enthusiasm.

Canova's sculptures have been distributed under three heads: 1. Heroic compositions; 2. Compositions of grace and elegance; and 3. Sepulchral monuments and relievos. In noticing the works which fall under each of these divisions, it will be impossible to maintain a strict chronological order, but perhaps a better idea of his productions may thus be obtained. Their vast number, however, prevents their being all enumerated.

Soon after his return appeared his Perseus with the head of Medusa. The moment of representation is when the hero, flushed with conquest, displays the head of the "snaky Gorgon," whilst the right hand grasps a sword of singular device. By a public decree, this great triumph of art was placed in one of the *stanze* of the Vatican, hitherto reserved only for the most precious works of antiquity. In 1802, at the personal request of Napoleon, Canova repaired to Paris to model a bust of the first consul. The artist was entertained with munificence, and various honours were conferred upon him. The statue, which is colossal, was not finished till six years after. On the fall of the living original, the French king presented this statue to the British government, by whom it was afterwards given to the Duke of Wellington. Palamedes, Creugas, and Damoxenus, the combat of Theseus and the Centaur, and Hercules and Lychas, all displaying great and varied excellence, may close the class of heroic compositions, although the catalogue might be swelled by the enumeration of various others, such as Hector and Ajax, the statues of Washington, Ferdinand, and others. The group of Hercules and Lychas is considered as the most terrible conception of Canova's mind, and in its peculiar style as scarcely to be excelled.

Under the second head, namely, compositions of grace and elegance, the statue of Hebe takes the first place in point of time. Four times has the artist embodied in stone the goddess of youth, and each time with some variation. The only material improvement, however, is the substitution of a support more suitable to the simplicity of the art. The invention merits the title of originality, and the figure in each of the statues is, in all its details, in expression, attitude, elegance, and delicacy of finish, perfect in beauty. The Dancing Nymphs maintain a character similar to that of the Hebe. The Graces and the Venus are more elevated, as combining dignity with elegance. The Awakened Nymph is another work of extraordinary beauty, a term indeed which may be applied to all his productions indiscriminately. The mother of Napoleon, Maria Louisa, to model whom the author made a second journey to Paris in 1810, the Princess Esterhazy, and the muse Polyhymnia, take their place in this class; as do the ideal heads, comprising Corinna, Sappho, Laura, and Beatrice. In these the artist combined reality with fancy; all are representations of celebrated females, and he has endeavoured to realize the glowing descriptions of poesy, or the more veracious traits of history, according to his own refined conceptions of character. Living models supplied the contour and the features, but these were kindled up with the soul of passion and expression by the sculptor's hand. Belonging to this class of composition the most glowing portraiture of female loveliness is the Helen of Troy.

The cenotaphs and funeral monuments fall next to be noticed. Of these the most splendid is the monument to the Arch-Duchess Maria Christina of Austria, consisting of nine figures. It is considered as a *chef-d'œuvre* in this department of art. Besides the two for the Roman pontiffs, already mentioned, there is one for Alfieri, another for Emo, a Venetian admiral, and a small model of a cenotaph for Nelson, besides a great variety of monumental relievos.

The events which marked the life of the artist during the first fifteen years of the period in which he was engaged on the above-mentioned works, are of so little importance as scarcely to merit notice. His mind was entirely absorbed in the labours of his studio, and, with the exception of his two journeys to Paris, one to Vienna, and a few short intervals of absence in Florence and other parts of Italy, he never quitted Rome. In his own words, "his statues were the sole proofs of his civil existence." There was, however, another proof, which modesty forbade him

to mention, an ever active benevolence, especially towards artists. In 1815 he was commissioned by the Pope to superintend the transmission from Paris, of those works of art which had formerly been conveyed there under the direction of Napoleon. By his zeal and exertions, for there were many conflicting interests to reconcile, he adjusted the affair in a manner at once creditable to his judgment and fortunate for his country. In the autumn of this year he gratified a wish he had long entertained, of visiting the British metropolis, where he was graciously received by the prince regent, and honoured with the highest tokens of esteem. He returned to Rome in the beginning of 1816, with the ransomed spoils of his country's genius. Immediately after, he received several marks of distinction: by the hand of the pope himself his name was inscribed in "the golden volume of the capitol," and he received the title of Marquis of Ischia, with an annual pension of 3000 crowns, about L.625.

He now contemplated a great work, a colossal statue of Religion. The model filled Italy with admiration: the marble was procured, and the chisel of the sculptor ready to be applied to it, when the jealousy of churchmen as to the site, or some other cause, deprived the world of the projected work. The mind of Canova was inspired with the warmest sense of devotion, and though foiled in this instance, he resolved to consecrate a shrine to the cause, at once worthy of himself and of the religion to which he was devoted. In his native village he began to make preparations for erecting a temple, which was to contain not only the above statue, but other works of his own; and within its precincts also were to repose the ashes of the founder. Accordingly, in prosecution of this design, he repaired to Passagno in 1819. At a sumptuous entertainment which he gave to his workmen, there occurred an incident which it is impossible to overlook in any life of Canova, however circumscribed. When the festivities of the day had terminated, he requested the shepherdesses and peasant girls of the adjacent hamlets to pass in review before him, and to each he made a present, expending on the occasion about L.400. We need not therefore be surprised, that, a few years afterwards, when the remains of the donor came to be deposited in their last asylum, the grief which the surrounding peasantry evinced was in natural expression so intense and irrepressible, as totally to eclipse all the studied solemnity of more pompous mourning.

After the foundation stone of this edifice had been laid, Canova returned to Rome; but every succeeding autumn he continued to visit Passagno, in order to direct the workmen, and encourage them with pecuniary rewards and medals. In the mean time the vast expenditure exhausted his resources, and compelled him to labour with unceasing assiduity, when age and disease had set their seal upon his frame. During the period which intervened between commencing operations at Passagno, and his decease, he executed or finished some of his most splendid works. Amongst these were the group Mars and Venus, the colossal figure of Pius VI., the Pietà, the St John, the recumbent Magdalen, and others of scarcely inferior excellence. The last performance which issued from his hand was a colossal bust of his friend the Count Cicognava. In May 1822 he paid a visit to Naples, to superintend the construction of wax-moulds for an equestrian statue of Ferdinand. This journey materially injured his health, but he rallied again on his return to Rome. Towards the latter end of the year he paid his annual visit to the place of his birth, when he experienced a relapse. He proceeded to Venice, and expired there on the 13th of October 1822, at the age of sixty-five. The most distinguished funeral honours were paid to his remains, which were deposited in the temple at Passagno on the 25th of the same month.

Canova is allowed to rank above every other master, from the age of Nicholas of Pisa. He renovated the art in Italy, and brought it back to the standard from which it had declined. His style in youth displayed the utmost simplicity; but as he proceeded in his career, he evinced the true poetic feeling which spiritualizes and exalts nature into ideal beauty and grandeur—that power which gives to marble features an expression apparently resulting from the workings of an inherent and active intelligence; in a word, he stamped them with the impress of the soul. His finishing was excessively refined, and he had a method of giving a mellow and soft appearance to the marble, hitherto unattempted. He formed his models of the same size as the work he designed was intended to be, which was, undoubtedly, a great improvement in the art. Of his moral character, a generous and unwearied benevolence formed the most prominent feature. Of the vast fortune realized by his works, the greater part was distributed in acts of this description. To artists in particular, his hand was "open as day to melting charity." He established prizes for them, and endowed all the academies of Rome. The aged and unfortunate were also objects of his peculiar solicitude. His titles were numerous. He was enrolled amongst the nobility of several states, decorated with various orders of knighthood, and associated in the highest professional honours. (See the *Life of Canova* by Memes, one vol.; by Missinini, four vols.; also the *Biografia*, by the Count Cicognava.) (J. F. S.)

CANSO, or CANCEAU, an island, cape, and small fishing bank, on the N.E. coast of Nova Scotia, about forty leagues east by north of Halifax. The island is small, but has a good harbour. The Gut of Canso forms the passage from the Atlantic into the Gulf of St Lawrence, between Cape Breton Island and Nova Scotia. Lat. 45. 20. N. Long 61. W.

CANSTATT, CANSTADT, or KANSTATT, a town of Würtemburg on the Neckar, not far from Stuttgard, at a point where the high roads of the circle converge. Besides the mineral springs for which it is famous, it possesses a fine cathedral, a beautiful town-hall, an educational institute, considerable manufactures of cottons, woollens, and tobacco, and an important transit trade. The adjoining country is remarkably picturesque and fertile. Seelberg, a hill in the vicinity, is upwards of 600 feet in height, and is interesting as well for the numerous mineral springs which issue from it, as for the valuable fossils with which it abounds. The summer theatre, and the pleasure house, are much frequented by the people of Stuttgard, who repair thither in great numbers during the vacation. In the neighbourhood is the princely seat of Rosenstein, formerly known under the name of Kahlenstein. Pop. 5400.

CANT, a quaint, affected style of speaking, either as regards the utterance or the subject itself. The term has been said to be derived from the name of a Cameronian preacher in Scotland, Andrew Cant, who by practice had attained the faculty of preaching in such a tone and dialect as to be understood by none but his own congregation. Since his time, the word has been extended to all affected exclamations and whining unmusical tones, especially in praying and preaching. The more probable derivation of the word, however, is from the Latin *cantare*, to sing; in which sense cant would be synonymous with sing-song.

CANT is also applied to unusual words and phrases affected by particular persons or professions. The difference between *cant* and *technical*, as applied to terms, seems to be, that the former is restricted to those introduced out of folly, affectation, or imposture; and the latter is applied to such as are introduced for the sake of clearness and precision.

CANT also denotes a call for bidders at an auction. Some derive the word, in this sense, from *quantum*, how much; others, from *cantare*, to sing or cry aloud.

CANTABRIA, a district of Hispania Tarraconensis, lying on the south coast of the Bay of Biscay. By the more ancient geographers, the name was applied to the entire country now occupied by the provinces of Asturias, Santander, Biscay, and Guipuzcoa. After the conquest of Spain by the Romans, the name of Cantabria was restricted to what is now the province of Santander and the eastern portion of Asturias. The Cantabrians were the most warlike of all the native Spanish tribes that the Romans had to encounter, and were never finally subdued. Along with the Astures, they offered for many ages a successful resistance to the Roman arms, and were only at last compelled to acknowledge the supremacy of Rome by Augustus. They revolted a few years after, but were cut off nearly to a man by Agrippa, B.C. 19. When their numbers began once more to increase, they again revolted, and were only kept in check by the most vigorous exertions of the emperor Tiberius. Their indomitable spirit is frequently alluded to in the ancient classics; among others, Horace alludes to the "*Cantabrum indoctum juga ferre nostra.*" Cantabria under the Roman empire comprehended five principal tribes,—the Pleitauri, the Varduli, the Autrigones, the Conisci or Concani (who fed on the blood of their horses,—"*lætum equino sanguine Concanum*"), and the Tuisi. There were numerous towns and villages distributed throughout the country, of which the most important was Juliobriga.

CANTABRUM, a large banner used during the time of the Roman emperors, and borne in festive processions.

CANTACUZENUS, JOHANNES, emperor of the East, celebrated as a statesman, general, and historian, was born at Constantinople, of an ancient and opulent family; and, under the reign of the elder Andronicus, he held the high office of Great Domestic. In the disputes that ensued between that emperor and his grandson, Cantacuzenus espoused the cause of the latter; and when Andronicus II., on the abdication of his grandfather, ascended the throne (A.D. 1328), this able minister was intrusted with the supreme administration of affairs, in which capacity he displayed extraordinary vigour and ability. On the death of the emperor in 1341, Cantacuzenus was left regent, and guardian of his son John Palæologus, who was but nine years of age. This trust he continued to discharge with fidelity, till the intrigues of the empress-mother and her faction rendered Cantacuzenus alarmed for his personal safety. Declared a traitor, he had but one resource; and accordingly he assumed the imperial purple in the autumn of 1321. A civil war ensued, which lasted six years, when he admitted John Palæologus as his colleague in the empire; and this union was confirmed by the marriage of Palæologus with the daughter of Cantacuzenus. Suspicions and enmities, however, soon arising, the war broke out again, and continued till John took Constantinople in 1355. A few days after, Cantacuzenus, unwilling to continue the effusion of blood, abdicated his share of the empire, and retired to a monastery, where he assumed the habit of a monk, under the title of Joasophas Christodulus. His wife also retired to a nunnery, and changed her name of *Irene* for that of *Eugenia*. In this retirement he lived till 1411, when he must have been upwards of a hundred years of age. Here he wrote a history of his own life and times, which has been incorporated in the series of the Byzantine historians; and also an apology for the Christian religion against that of Mohammed, under the name of *Christodulus*.

CANTAL, a department in central France, lying between N. Lat. 44. 37. and 45. 26. and between E. Long. 2. 3. and 3. 18: bounded north by the department of Puy-de-Dôme; east by the Haute-Loire and Lozère; south by Aveyron; west by Corrèze and Lot. Area 1950 square miles.

It is formed of the ancient province of Upper Auvergne, and received its name from the Plomb-du-Cantal, the central peak of a bare and rugged chain which traverses the whole department. Near the Plomb, which attains a height of above 6000 feet, are the Col-de-Cabre, and other peaks belonging to the same system. They are evidently of volcanic origin; and volcanic agency may be traced in the strata of lava with which several valleys have been filled up, and which are exposed in the sides of the water courses. The slopes of the higher mountains are steep and bare, and the more elevated valleys thinly peopled. In summer they afford pasture for the flocks and herds which migrate thither from the low countries. Most of the streams of the department have their sources in this central ridge, and fall by a short and rapid course into the rivers which traverse the extensive valleys on either side. The Aragnon, which rises on the east, is a tributary of the Allier; the Celle and Truyère are tributaries of the Lot; the Cère and the Rue, into which the Santoire falls, are tributaries of the Dordogne. The climate of the department varies considerably in the different localities. In the alluvial plain between Murat and St Fleur, and in the S.W. in the arrondissement of Aurillac, the climate is generally mild and dry; but in the northern and central portions the winters are long and severe, and the hurricanes peculiarly violent. The internal resources of the department are considerable; but, from the difficulty of land-carriage over a rough and broken surface, they are prevented from being sufficiently developed. The hills and valleys are stocked with game, and the streams with fish. In the botanical kingdom it produces a vast variety of aromatic and medicinal plants; and its mineral products include coal, copper, lead, iron, antimony, granite, slate, &c.; but of these natural sources of wealth little advantage is taken by the inhabitants. The cold and damp of the climate are insuperable obstacles to the successful cultivation of corn, which has therefore to be imported from the neighbouring departments; but the extent and richness of the pastures render the rearing of cattle and horses for exportation a profitable source of remuneration. Butter and cheese are made in large quantities, and the wool of the district is of a very superior quality. The manufactures of Cantal are inconsiderable, consisting chiefly of coarse woollen and linen stuffs, paper, brazier's work, cooper's work, glass, and leather. The inhabitants are a rude and uncultivated race, accustomed to live on the scantiest fare, and plying the meanest handicrafts for a considerable part of the year in their migrations to Paris and through the provinces. The principal articles of food are rye, buckwheat, and chestnuts.

The department is comprised within the military division of Clermont-Ferrand, and the tribunals hold of the royal court of Riom. It forms the see of a bishop, who is suffragan to the archbishop of Bourges.

The divisions and population of the department are as follows:—

Arrondissements.	Cantons.	Communes.	Pop. (1851).
Aurillac	8	93	96,433
Mauriac	6	57	63,346
Murat	3	34	35,309
Saint Fleur	6	74	58,241
Total	23	258	253,329

CANTARINI, SIMONE, called *Simone da Pesaro*, a celebrated painter and engraver, born at Pesaro in 1612. He was a disciple of Guido, and a fellow student of Domenichino and Albano. The irritability of his temper was extreme; and it is said that his death, which took place at Verona in 1648, was occasioned by chagrin at his failure in a portrait of the Duke of Mantua. Others relate that he was poisoned by a Mantuan painter whom he had injured. His pictures, though masterly and spirited, are deficient in originality. Some of his works have even been mistaken for those of Guido.

CANTEMIR, DEMETRIUS, son of a prince of Moldavia, born in 1673; died in 1723. Disappointed in not succeed-

ing his father in that dignity, which was held under the Ottoman Porte, he went over with his army to the Czar Peter, against whom he had been sent by the Grand Signior. He signalized himself in the czar's service, and wrote in Latin a History of the Growth and Decay of the Ottoman Empire, which has been translated into almost every language in Europe. This once popular work is now known to be taken principally from an inaccurate abridgment and continuation of Saad-ed-deen's great Turkish history. (See *Journal Asiatique*, anno 1824, tom. iv.)

Cantemir, *Antiochus*, the father of Russian poetry, was the youngest son of the preceding, and was born in 1700. Under the ablest professors, whom the czar had invited to Petersburg, he studied mathematics, physics, history, moral philosophy, and polite literature. After completing his academic course, he published in the Russian language a Concordance to the Psalms, and was elected a member of the academy. When only twenty-four years of age he was nominated as minister to the court of Great Britain; and here, as well as in France, whither he went in 1738 as minister plenipotentiary, he was equally admired as a statesman and a man of letters. Subsequently he was ambassador-extraordinary at the courts of Britain and France successively. His wise and prudent conduct in relation to the different revolutions which agitated Russia during his absence, procured him the confidence and esteem of three successive princes. This accomplished man died at Paris in 1744, at the age of forty-four. Besides a Russian translation of Anacreon and the Epistles of Horace, he wrote original satires, odes, and fables, and translated Fontenelle's *Plurality of Worlds*, and Algarotti's *Dialogues on Light and Colours*. The Abbé Guasco has written his life in French, and translated his satires into that language.

CANTERBURY, a municipal and parliamentary borough in the county of Kent, 55 miles S.E. from London, or 81 miles by the South-Eastern railway. N. Lat. 51. 17., E. Long. 1. 4. It is situated on the river Stour, but its trade is carried on through the small port of Whitstable in Herne Bay, with which it communicates by rail. The municipal corporation consists of 6 aldermen, one of whom is mayor, and 18 councillors. By a very ancient statute, it is entitled to return two members to parliament. In a commercial point of view, Canterbury is a town of little importance. Its inhabitants are principally engaged in the corn, wool, and hop trades. The mills in the neighbourhood are driven by water-power derived from the river. The manufacture of silk was introduced here by the French refugees, to whom Queen Elizabeth granted the use of the cathedral crypt; but, as in other places of the empire, it became extinct with the original colony which had projected it. Recent improvements have rendered Canterbury a very desirable place of residence, and in the vicinity are several handsome villas and gentlemen's seats. Its principal modern public buildings are the corn-exchange, philosophical museum, and town-hall. It contains some mineral springs which are highly valuable for their medicinal properties. Pop. (1851) 18,398.

Ecclesiastical Antiquities.—The most famous is the cathedral, the foundation of which is said to have been laid in the time of Augustine, when that monk was sent by Gregory I. to convert the Angles, although the present building cannot be traced beyond the twelfth century. Since the date of its foundation it has suffered severely, at first from the fires of the Danish invaders, and at other times from accidental conflagrations; but from the zeal of its archbishops (amongst whom Lanfranc and Anselm are most conspicuous), and the treasures which it amassed from the crowds of pilgrims who resorted to it, it quickly recovered from its disasters. From the frequency of these repairs arises the motley character of its architecture. The cathedral is built in the form of a double cross, and has an extreme length of above 500 feet. The most remarkable objects are the great Bell Harry tower, and Becket's crown which forms the eastern part. The crypts, which are of immense size, contain the remains of several ancient paintings; and the monuments of Henry IV., Edward the Black Prince, &c., are of the most magnificent description. After the canonization of Thomas à Becket, who was assassinated beside the altar by the emissaries of Henry II., the shrine was visited, and the cathedral gifted with a small endowment by Louis VII. of France, and it was enriched by costly presents from the nobility and ecclesiastics of both nations. Mercery Lane, the name still given to the principal approach to the cathedral, shows that traffic was not forgotten by the pious visitors. The treasures of the cathedral were confiscated by Henry VIII., and fresh exactions were levied from it in the time of Edward VI. It was partly demolished during the parliamentary contests, and it is only in recent times that it has been thoroughly repaired.

Next to the cathedral in importance are the remains of the monastery of St Augustine, by whom it is said to have been founded. The greater part of it was destroyed by fire at the same time with the cathedral; and since the Reformation the remaining portion has been occupied successively as a royal palace, a private residence, and a public brewery. The old edifice has been recently restored and constituted by royal charter into a missionary college in connection with the establishment.

Of the churches of Canterbury the most ancient is that of St Martin in the suburbs. It is partly built of Roman and Norman remains, and has been carefully repaired. In the vaults of the Roper family, underneath St Dunstan's church, the head of Sir Thomas More was deposited after it had been exposed on Temple-Bar. The churches of Saint Mary Magdalen and St Mildred are also edifices of considerable antiquity. Of the numerous hospitals and alms-houses which once existed in the neighbourhood, scarcely any trace can be found.

Canterbury is a town of great antiquity, and held an important place both during the Roman occupation and under the Saxon heptarchy. Its Roman name was Durovernum, part of which is a corruption of the British *dwr*, and seems to refer to the Stour. It was the capital of Kent, and the residence of King Ethelbert, when Augustine landed on the island. Of its walls and gates the ruins have long since disappeared.

The archbishop of Canterbury is primate of all England and metropolitan. The jurisdiction of the ecclesiastical province comprehends the dioceses of Canterbury, Bangor, Bath and Wells, Bristol, Chichester, Ely, Exeter, Gloucester and Bristol, Hereford, Lichfield, Lincoln, Llandaff, London, Norwich, Oxford, Peterborough, Rochester, St Asaph, St David's, Salisbury, Winchester, and Worcester. Present value of income, L.15,000. The succession of archbishops has been as follows; the dates give the year of appointment.

A.D.		A.D.	
596.	St Augustine.	793.	Athelard.

1768.	Hon. Frederick Cornwallis.
1783.	John Moore.
1805.	Charles Manners Sutton.
1828.	William Howley.
1848.	John Bird Sumner, the present archbishop.

(Haydyn's *Book of Dignities.*)

CANTERUS, William, an eminent linguist and philologer, born at Utrecht in 1541. He studied at Louvain and Paris under Valerius and Aratus, and, after visiting the German and Italian universities, retired to Louvain, where he died in 1575. He was familiar with Latin, Greek, Hebrew, French, Italian, and German literature, and published several works, which deserve notice as almost the earliest specimen of scientific criticism and philosophy. These are, *Novæ Lectiones*, 8vo, Basle, 1564; *Aristidis Orationes*, fol., Basle, 1566; *Nota, scholia, emendationes, et explicationes in Euripidem, Sophoclem, Æschylum, Ciceronem, &c.* (See his Life, in Melchior Adam's Collection.) His brother Theodore (born 1545, died 1617), was also a scholar and critic of some eminence. His critical works are published in Gruter's *Thesaurus Criticus*.

CANTHARIDES (κανθαρίς), or Spanish flies, are used as the common vesicatory or blistering-plaster. The largest are found in Italy, but the best come from Spain. See Entomology.

CANTICLES, or Song of Solomon, one of the books of the Old Testament, is placed in our modern collection immediately before the prophetical books, but generally stands fourth in the *Hagiography* of the Jews. There is no other inspired book concerning which (at least in modern times) so great diversity of opinion has existed; and the points of attack have been severally its canonicity, its authorship, its structure, and its interpretation. In regard to the first of these, the denial of its canonicity, this has been based more on æsthetical than on historico-critical considerations, although some writers (such as Whiston, and Dr Pye Smith) have attempted to show that, because it cannot hold a place in any of the groups into which the catalogue of Josephus is divided, it is therefore to be regarded with great suspicion. This is an opinion which has been generally abandoned by modern critics. It is utterly untenable when weighed against the fact of its existence in all the MSS., in all the detailed catalogues which have come down to us, in the Septuagint, and the versions of Symmachus and Aquila. The denial of its authorship by Solomon is a fundamental principle of that school of criticism which denies the unity, and consequently the single authorship, of all the great poems of antiquity. In this respect it has only shared the fate of the Iliad and Odyssey. With endless variety in the details, the critics of this class all agree in regarding it as a collection of songs by different authors, compiled and edited by a later hand. To what an extent this disintegrating criticism has been carried, may be seen from the scheme of Magnus (*Kritische Bearbeitung und Erklärung des Hohen Liedes*, 1842), who detects in Canticles no fewer than forty-four different parts, complete and fragmentary, early and late, glossarial and spurious. This is justly regarded by most later critics as inconsistent with the sameness that prevails throughout the whole collection. The sameness of the subject, of the recurring formulæ, of the Aramaic colouring and idiom, and of the personages introduced, all combine to mark the Song of Songs, like the holy of holies, as an individual *unity*. In regard to its author, the unvarying testimony of tradition is decisive in favour of Solomon, and there are many things in the style of the book to sanction this view. The wide circle of its imagery, drawn from the most remote localities, if not also the freshness and vigour of its style, point to an age anterior to the dismemberment of the kingdom; at the same time that the allusions to foreign equipages (i. 9), and the introduction of foreign words (iv. 13, iii. 9), strikingly coincide with Solomon's *penchant* for exotic grandeur. In regard to the structure of the book, critics have more widely differed. Bossuet regards it as a pastoral eclogue, divided into plots of seven days, commensurate with the celebration of a marriage-feast; Eichhorn divides it into a number of detached but systematized idyls; Ewald into a drama of four, Delitzsch of six, acts; while others split it into sections and subsections, on an endless variety of principles. The difficulty attaching to all the schemes is that they are too artificial. Any of them may, none of them must, be true; but the dramatic and semi-dramatic theories are inconsistent with the entire absence of any progress in the plot. With all the change of scenery there is no change of the relations subsisting between the parties who are introduced in each successive scene. The more probable solution appears to be, that it is entirely destitute of any plan, and that, as it aims simply at placing the love of the king and his bride in a variety of aspects, it is consistent with such abrupt transitions as may easily be mistaken for the commencement of separate acts.

The interpretation of the Canticles is the point at once the most important, and, within certain limits, the most keenly contested. Disregarding the questions that have been raised in regard to the origin of the poem, we may divide the various methods of interpretation into the three great classes of literal, typical, and allegorical. Those who interpret it literally, still regarding it as Solomon's, hold it to be an erotic poem, the heroine of which is either Pharaoh's daughter or a simple country maiden introduced into his court. Others, who regard it as a collection of detached songs or idyls, find in them the loving converse of a chaste pair, either before or after marriage. Of this class, some hold it to be utterly destitute of a moral at all; others recognise in it an ethical value, as commending monogamy, or as setting forth the beauty of conjugal fidelity in the faithfulness of Shulamith. On any of these hypotheses it seems impossible to account for or vindicate the placing of Canticles in the canon of

Scripture. Its language—which is, however, far more delicate in the Hebrew than in any European dress—might be used in the harem as well as at the hearth, and it is as void of any reference to the religious import and religious duties of marriage or monogamy as are the odes of Hafiz or Anacreon. The typical interpretation stands half-way between the literal and allegorical. It regards the primary aim of the Canticles as being a celebration of Solomon's marriage with his one favourite wife, at the same time that the parties described are raised to the rank of ideals or types of the marriage union, which has its antitype in the union of Christ and the church. This mode of interpretation, although—by investing the composition with a higher ethical meaning—it rises from the degradation of the literal, and approaches indefinitely near the higher spiritual signification, yet is unfortunate in having to bear the burdens of both without the advantages of either scheme. By those who have held the allegorical view various solutions have been given, most of them more remarkable for their ingenuity than their verisimilitude. One theory regards it as a delineation of the fortunes of Israel at various epochs of their history; another as marking the relation of the Jewish church to Christ, before and after his advent; and a third as illustrating the betrothal of Japhetic and Hametic heathendom to the Saviour.

But the interpretation which has been sanctioned by the concurrent testimony of Jewish and Christian antiquity is that which regards it as an allegory descriptive of the love of Jehovah to Israel, of Christ to his church. The arguments in favour of this view are derived from the inconsistencies that defy any literal interpretation; the intimations of collective plurality in that of which the bride is the representation (i. 4, i. 9, iii. 6, &c.); and the prominence given to the fundamental figure of the conjugal relation of Jehovah to the church in the Old, and in some passages of the New Testament. It remarkably corroborates this view, that the same idea is seen to colour the denunciations of all the posterior prophets, who freely borrow the language applicable to a violation of the seventh in order to designate a breach of the second commandment. This is the view which has prevailed almost universally in the synagogue and in the church till within a very recent period. It does not seem to have been challenged till the sixth century, when the literal interpretation formed a count in the condemnation of Theodore of Mopsuestia; and though Jerome approves of what seems to have been the Jewish rule in his day, which forbade all below thirty years of age to read it, this scrupulous jealousy was accompanied by no suspicions of the truth of its spiritual meaning. From Theodore in the sixth to Castellio in the sixteenth century, the literal interpretation had no advocate; and when first brought forward it was everywhere rejected as sacrilegious. From the period of the Reformation it again lay quiescent till revived in Germany by the Rationalists of last century, among whom it has since held undisputed sway. The most recent interpreters, however, in that country—Delitzsch, Hahn, and Hengstenberg—seem to be retracing their steps, through the typical and semi-allegorical, back to the ancient allegorical interpretation. (R. W—N.)

CANTILEVER, or Cantaliver, a support projecting from the front or the side of a building to sustain the eaves, mouldings, &c. The word is perhaps derived from *canterii labrum*, the lip of a rafter.

CANTIUM, in *Ancient Geography*, the name of a district in Britain, nearly corresponding with the county of Kent. The inhabitants, *Cantii*, were noted for being considerably in advance of the rest of the Britons in civilization.

CANTO (Italian *canto*, a song), a part or division of a poem, answering to what in prose is called a *book*.

CANTO-FERMO (literally *firm song*), in *Music*, the subject song. This term is applied by the Italians to every part that is the subject of counterpoint, whether plain or figured.

CANTON, a small district or portion of territory constituting a distinct state or government, as in Switzerland.

Canton, a large and populous commercial city of China, in the province of Quang-tong, situated on the eastern bank of the Pekiang river, which at Canton is somewhat broader than the Thames at London Bridge, and is navigable 300 miles farther into the interior. It has an additional course of 80 miles to the sea, near its junction with which it takes among foreigners the name of Bocca Tigris, or the mouth of the Tigris, from the appearance of one of the islands at its entrance. When viewed from the hills on the north, Canton appears to be little more than an expanse of reddish roofs relieved by a few large trees; two pagodas shooting up within the walls, and a five-storied tower near the northern gate, being the most conspicuous objects. These hills rise 1200 feet above the river. Little or no vegetation is seen on them; and their acclivities, covered for miles with graves and tombs, serve as the necropolis of this vast city. Three or four forts are built on the points nearest the northern walls. In the river opposite Canton is the suburb and island of Honam. The part of Canton inclosed by walls is about six miles in circumference, and has a partition wall, running east and west, and dividing the city into two unequal parts. The northern and larger division is called the old, and the southern the new city. Including the suburbs, the city has a circuit of nearly ten miles. The houses stretch along the river for four miles, and the banks are everywhere nearly concealed by boats and rafts. The walls of the city are of brick, on a foundation of sandstone, and are 20 feet thick, and from 25 to 40 feet high. There is an esplanade on the inside, with pathways leading to the rampart on three sides. The walls were formerly surrounded by a ditch, which is now dry on the northern side, but on the other three, and within the city, it and most of the canals are filled by the tide, and present a revolting mass of filth when the retiring waters expose the bottoms. There are twelve outer gates—four in the partition wall, and two water gates, through which boats pass from east to west across the new city. The gates are all shut at night, and a guard is constantly stationed at them to preserve order. The streets, amounting in all to upwards of 600, are long, straight, and very narrow, paved with little round stones, and flagged at the sides of the houses. They are not so dirty as those of some of the other cities in the empire; and considering the habits of the people and the inattention of government to these matters, it may be said to be a well-governed and comparatively cleanly city. The houses are in general small, seldom consisting of more than two stories, the lower story serving as a shop in which goods are exhibited for sale, and the rest of the house, with the court behind, being used as a warehouse. Particular streets are allotted for the supply of strangers; others to particular classes of artizans. The principal street appropriated to Europeans is denominated China Street. Here are to be found the productions of every quarter of the globe; and the merchants are in general extremely attentive and civil. The Chinese are remarkably expert men of business, and of the most assiduous habits. They are always to be seen sitting on their counters, and using every effort to attract the attention of the British seamen who are in the habit of frequenting this quarter of Canton. They have an English name painted on the outside of their shops, besides a number of advertisements composed for them by the sailors in their peculiar idiom. They contrive in this manner to draw the seamen into their shops, and occasionally to impose upon them by their specious manners and command of temper. The temples and public buildings of Canton are numerous; but none of them present features worthy of special remark

There are two pagodas near the west gate of the old city, and 124 temples, pavilions, halls, and other religious edifices within the city. One of the pagodas called the *Kwang-tah*, or plain pagoda, was erected by the Mohammedans about ten centuries ago, and rises in an angular tapering tower to the height of 160 feet. The other is an octagonal pagoda of 9 stories, 170 feet in height, and was first erected more than thirteen centuries ago. A Buddhist temple at Honam, opposite the foreign factories, and usually known as the Honam Josshouse, is one of the largest in Canton. Its grounds cover about seven acres, surrounded by a wall, and divided into courts, garden-spots, and a burial-ground, where are deposited the ashes of priests, whose bodies are burned. There are about 175 priests connected with this establishment, of whom only a small number can read. Besides the Honam temple, there are two others in the old city, belonging to the Buddhists, both of which are likewise well endowed. The number of priests and nuns in Canton is not exactly known, but they probably exceed 2000, nine-tenths of whom are Buddhists. The temples are gloomy-looking edifices. The areas in front of them are usually occupied by hucksters, beggars, and idlers, who are occasionally driven off to make room for the mat-sheds in which the theatrical performances got up by the priests are acted. The principal hall where the idol sits enshrined is lighted only in front, and the inner apartments are inhabited by a class of men almost as senseless as the idols they serve.

The residences of the high officers of government are all within the walls, some in the Old, and some in the New City. The residence of the governor-general is in the S.W. corner of the New City, and comprises a large number of buildings for the accommodation of himself and attendants. The collector of customs resides eastward of the governor-general. The residence of the commander-in-chief is in the Old City, and said to be one of the best houses in Canton. There are four prisons in the city, all large edifices. The factories of the different European powers trading here extend a considerable distance along the banks of the river, fronting the city at about a hundred yards from the water. They consist of large and handsome houses, on which are hoisted the respective flags of the different nations. By the Chinese these factories are called *hongs;* they resemble long courts without a thoroughfare, and generally contain four or five separate houses. They are built on a fine quay; and a broad parade extends along the river in front of the factories, whither the European merchants, and commanders and officers of ships, resort to enjoy the cool of the evening. The British factory far surpasses all others in elegance and extent. It has a large verandah, reaching nearly down to the water's edge, raised on handsome pillars, and paved with marble, and commanding an extensive view along the river banks. There are spacious warehouses in the neighbourhood for the reception of goods, as well as Chinese dwellings, which are let to merchants who visit Canton. For the space of four or five miles opposite Canton boats and vessels are ranged parallel to to each other in such close order that it resembles a floating city; and these marine dwellings are occupied by numerous families, who reside almost constantly on the water. In the middle of the river lie the Chinese junks, which trade to the eastern islands and Batavia, and which are moored head and stern, some of them of the burden of 600, and even of 1000 tons. The various guilds and associations among the people and the merchants from other provinces have each public halls for their own particular use. The number of these buildings is not less than 150. Canton was long the only, and is still the principal seat of the British trade with China. As a place of traffic, it labours under the great disadvantage that from the shallowness of the river most of the vessels cannot ascend farther than about eight miles from the city, and every British merchant-man is obliged to anchor at Whampoa, nine miles from the city; whereas at Shanghae ships can anchor close to the English wharfs. The trade of Canton is retrograding, while that of Shanghae is increasing; and indeed it is not unlikely that the latter will in time supplant Canton in the European trade, as it enjoys the additional advantage of being nearer the tea districts. Canton was no doubt fixed upon by the Chinese government for the European trade, as being the most distant from the capital Pekin.

Formerly only a limited number of merchants, called the hong or security merchants, were allowed to trade with foreigners. They were commonly men of large property, and were famed for integrity in their transactions. All foreign cargoes passed through the hands of these merchants, and by them also the return cargoes were furnished. They became security for the payment of duties, and it was treason for any other merchant to engage in the trade with foreigners. This severe law, however, has recently been abolished, and foreigners may now deal with any merchant they think fit to employ.

Accounts are kept in *tales, mace, candarines,* and *cash;*—ten cash being one candarine, ten candarines one mace, ten mace one tale, which last is converted into English money at 6s. 8d., though it is intrinsically worth only 6s. The coin called cash is of base metal, cast, not coined, and very brittle. It is of small value, and varies in the market from 750 to 1000 cash for a tale. Its chief use is in making small payments among the lower classes. Spanish and other silver coins are current, and are estimated by their weight; every merchant carrying scales and weights with him. All the dollars that pass through the hands of the hong merchants bear their stamp; and when they lose their weight in the course of circulation they are cut in pieces for small change. The duties are paid to government in sycee, or pure silver, which is taken by weight. In delivering a cargo, English weights and scales are used, which are afterwards reduced to Chinese catties and peculs. A pecul weighs 133⅓ pounds avoirdupois, and a catty 1⅓ pound. Gold and silver are also weighed by the tale and catty, 100 tales being reckoned equal to 120 ounces 16 pennyweights troy. All goods are sold by weight in China—even articles of food, such as fowls, hogs, and the like.

The foreign trade of Canton is very extensive; but the great article of export is tea, for which the demand in Europe has been increasing for upwards of a century. This article was formerly monopolized by the East India Company; and from their accounts it appears that they imported annually into this country about thirty millions of pounds. But this monopoly was abolished in 1834, and the commerce with China was thrown open to all classes of his majesty's subjects. The other exports are raw silk and silk manufactures, nankeen cloth, cassia, lignea, &c. The principal imports from the United Kingdom are cotton and woollen goods, earthenware, iron, steel, &c. In 1848, 176 British vessels of 73,975 tons, with goods of the value of 8,653,033 dollars left, and 171 of 72,315 tons, with goods to the value of 6,534,597 dollars, entered the port of Canton. The Americans, French, and Dutch, also carry on a considerable trade with Canton.

Although situated in the same parallel of latitude as Calcutta, the climate of Canton is much cooler, and is considered superior to that of most places situated between the tropics. The thermometer, during the months of July and August, averages from 80° to 88°; and in January and February from 50° to 60°. The highest recorded observation in 1831 was 94° in July, and the lowest 29° in January. In shallow vessels, ice sometimes forms at Canton a line or two in thickness. A fall of snow, nearly two inches deep, occurred at Canton in February 1835, and remained on the ground three hours,—a circumstance so unusual that the citizens hardly knew its proper name. Fogs are common during February

and March. Most of the rain falls during May and June, but it is nothing in comparison of a rainy season in Calcutta. July, August, and September, are the regular monsoon months, the wind coming from the S.W., with frequent showers, which allay the heat. In the succeeding months the northerly winds commence with some interruptions at first, but from October to January the temperature is agreeable, the sky clear, and the air invigorating. Few large cities are more healthy than Canton; no epidemics nor malaria prevail there, though much of the town is built upon piles.

Provisions and refreshments of all sorts are abundant at Canton, and in general are excellent in quality and moderate in price. It is a singular fact, that the Chinese make no use of milk, either in its natural state, or in the form of butter or cheese. Among the delicacies of a Chinese market are to be seen horse-flesh, dogs, cats, hawks, owls, and edible birds'-nests. The business at Canton is generally transacted in a jargon of broken English, the Chinese being extremely ready in acquiring such a smattering of English words as to render themselves intelligible; and the lower classes of them are frequently hired as servants by the Europeans.

The intercourse between China and Europe by the way of the Cape of Good Hope began in 1517, when Emanuel, king of Portugal, sent a fleet of eight ships, with an ambassador, who was conveyed to Pekin, and who obtained the sanction of the emperor to establish a trade at Canton. It was in 1596, in the reign of Queen Elizabeth, that the English first attempted with two ships to open an intercourse with China; but they were lost in the outward voyage. About 1634 several English ships visited Canton; but a misunderstanding having occurred with the Chinese authorities by the treachery of the Portuguese, a rupture and a battle took place, and it was with difficulty that this misunderstanding was rectified. China was again visited in 1673 by an English ship that was refused admission into Japan. In 1677 a factory was established at Amoy; but in 1680 the factory was destroyed by an irruption of the Tartars, and it was not till 1685 that the emperor permitted any trade with the Europeans. Upon the union of the two East India Companies in London, an imperial edict was issued, restricting the European commerce to the port of Canton. Tea was first imported about the year 1667. This is one of the five Chinese ports opened to Europeans by the treaty of 1842. See CHINA.

CANTON, *John*, an ingenious natural philosopher, born at Stroud in Gloucestershire, in 1718. Among those with whom he became acquainted in early life was Dr Henry Miles of Tooting, a member of the Royal Society, and of approved eminence in natural science and philosophy. This gentleman perceiving that Mr Canton possessed abilities too promising to be confined within the narrow limits of a country town, prevailed on his father to permit him to go to London. Accordingly he arrived at the metropolis in March 1737, and resided with Dr Miles at Tooting till the 6th of May following, when he articled himself for the term of five years as a clerk to Mr Samuel Watkins, master of the academy in Spital Square. In this situation, his ingenuity, diligence, and conduct were so conspicuous, that on the expiration of his clerkship in May 1742 he was taken into partnership with Mr Watkins for three years. He afterwards succeeded that gentleman in Spital Square, and there continued during the remainder of his life. In 1744 he married Penelope, the eldest daughter of Mr Thomas Colbrooke.

Towards the end of 1745, electricity, which seems early to have engaged Canton's notice, received a very important improvement by the discovery of the Leyden phial. This event turned the thoughts of most of the philosophers of Europe to that branch of natural philosophy; and Canton, who was one of the first to repeat and to pursue the experiment, found his assiduity and attention rewarded by many valuable discoveries. Towards the end of 1749 he was concerned with his friend Benjamin Robins in making experiments in order to determine to what height rockets may be made to ascend, and at what distance their light may be seen. In 1750 was read at the Royal Society Canton's "Method of making Artificial Magnets, without the use of, and yet far superior to, any natural ones." This paper procured him the honour of being elected a member of the society, and the award of their gold medal. The same year he was complimented with the degree of M. A. by the University of Aberdeen; and in 1751 was chosen one of the council of the Royal Society.

In 1752 Canton was so fortunate as to be the first person in England who, by attracting the electric fire from the clouds during a thunder-storm, verified Dr Franklin's hypothesis of the identity of lightning and electricity. Next year his paper entitled "Electrical Experiments, with an attempt to account for their several phenomena," was read at the Royal Society. In the same paper he mentioned his having discovered, by a great number of experiments, that some clouds were in a positive, and some in a negative, state of electricity. Dr Franklin, much about the same time, made a similar discovery in America. This circumstance, together with Canton's constant defence of the doctor's hypothesis, induced that philosopher immediately on his arrival in England to pay him a visit, and gave rise to a friendship which ever afterwards continued without interruption. In the Lady's Diary for 1756, Canton answered the prize question that had been proposed in the preceding year. The question was, "How can what we call the shooting of stars be best accounted for; what is the substance of this phenomenon; and in what state of the atmosphere doth it most frequently show itself?" and the solution, though anonymous, proved so satisfactory to his friend Mr Thomas Simpson, who then conducted that work, that he sent Canton the prize, accompanied with a note, in which he said he was sure that he was not mistaken in the author of it, as no one besides, that he knew of, could have answered the question. Canton's next communication to the public was a letter in the *Gentleman's Magazine* for September 1759, on the electrical properties of the tourmalin, in which the peculiarities of that stone are stated in a very concise and elegant manner. On the 13th December, in the same year, was read at the Royal Society a paper of his entitled "An attempt to account for the regular diurnal variation of the Horizontal Magnetic Needle; and also for its irregular variation at the time of an Aurora Borealis." A complete year's observations of the diurnal variations of the needle are annexed to this paper. On the 5th November 1761, he communicated to the Royal Society an account of the Transit of Venus, 6th June 1761, observed in Spital Square. His next communication to the Society was a letter addressed to Dr Franklin, and read in February 1762, containing some remarks on Mr Delaval's electrical experiments. On the 16th December in the same year he published a paper entitled "Experiments to prove that water is not incompressible." These experiments are a complete refutation of the famous Florentine experiments, which so many philosophers have mentioned as a proof of the incompressibility of water. On St Andrew's day 1763, he was for the third time elected one of the council of the Royal Society; and on the 8th November in the following year were read before that learned body his further "Experiments and observations on the compressibility of water and some other fluids." The establishment of this fact, in opposition to the received opinion, formed on the hasty decision of the Florentine Academy, was thought to be deserving of the society's gold medal. It was accordingly moved for in the council of 1764; and after several invidious delays, which terminated much to his honour, it was presented to him on the 30th November 1766.

His next communication to the Royal Society was made in December 1768, entitled "An easy method of making a phosphorus that will imbibe and emit light like the Bolognian stone; with experiments and observations." The dean and chapter of St Paul's having, in a letter to the president, dated 5th March 1769, requested the opinions of the Royal Society relative to the best and most effectual method of fixing electrical conductors to preserve that cathedral from damage by lightning, Canton was one of the committee appointed to take the letter into consideration, and to report upon it. The gentlemen joined with him in this business were Dr Watson, Dr Franklin, Mr Delaval, and Mr Wilson. Their report was made on the 8th of June following, and the method recommended by them was carried into execution. The last paper of Canton's which was read before the Royal Society was on the 21st December 1769, contained "Experiments to prove that the Luminousness of the Sea arises from the putrefaction of its animal substances." Besides these, he wrote a number of papers both in earlier and in later life, which appeared in several publications, and particularly in the *Gentleman's Magazine*.

The close and sedentary life of Canton, arising from an unremitted attention to the duties of his profession, and to the prosecution of his philosophical inquiries and experiments, probably contributed to shorten his days. He died of a dropsy in the chest, on the 22d of March 1772.

CANTONI, Simone, a Milanese architect, who after studying at Rome settled in his own country, where he erected several palaces, and the halls of the Lyceo and Seminario, in a good Italian style of architecture. His principal work is the council-hall in the ducal palace at Genoa, where his father had formerly been employed. He died in 1818.

CANTONING, in the military art, the allotting separate quarters to each regiment.

CANTON'S PHOSPHORUS, is made by mixing three parts of calcined oyster-shells with one of flowers of sulphur, and exposing the mixture to a strong heat in a covered crucible for an hour. If exposed to the sun's light for a few seconds, it will shine in a dark room for some minutes afterwards. It must be kept in a well-stopped bottle.

CANTRED, or Cantreth, a hundred villages. It is a British word, compounded of the adjective *cant*, hundred, and *tref*, a town or village. In Wales some of the counties are divided into cantreds, as in England into hundreds.

CANTYRE, a peninsula of Scotland, forming the most southern part of the county of Argyll. The *Mull of Cantyre* is its most southern point, and has a lighthouse with a fixed light, seen 22 miles off.

CANUS, or Cano, Melchior (1523–1560), a learned Spanish bishop and theologian, who succeeded Vittoria as professor of theology at Salamanca. From his violent opposition to the establishment of the Jesuits in his native country, he was summoned by Paul III. to the council of Trent, and appointed bishop of the Canaries. By his influence with Philip II., Canus succeeded in frustrating the schemes of his enemies and procuring his recal to Castile, where he became provincial of the Dominican order. His principal works are entitled *Prælectiones de Pœnitentia; de Sacramentis;* and *Locorum Theologicorum, libri* xii. Two 8vo editions of his works were published at Cologne in 1605 and 1678; and a 4to edition at Venice in 1759.

CANUSIUM, now Canosa, an old and celebrated town of Apulia, on the right bank of the Aufidus, 15 miles from the mouth of that river, and 6 miles from the ancient Cannæ. Like very many of the more important cities in this part of Italy, it is said to have been founded by the Grecian hero Diomed: the origin of the city, however, can be traced with tolerable certainty to the Pelasgi. Canusium is first mentioned in history as assisting the Samnites in their wars against the Romans, by whom it was subdued for the first time B.C. 318. In the second Punic war the inhabitants gave a strong proof of their patriotism by sheltering within their walls the relics of the Roman army, which retreated thither after the rout at Cannæ. In the second year of the social war, in which Canusium joined the revolted allies, it was besieged unsuccessfully by the Romans. In the civil wars it suffered severely, but always contrived to secure its municipal privileges, and was never colonized from Rome till the days of Marcus Aurelius. Canusium is repeatedly mentioned in the Latin classics. In the *Iter ad Brundusium* of Horace, its bread is described as gritty, and its water is extremely scanty. This last defect was remedied by Herodes Atticus, who constructed an aqueduct, of which the remains are still visible. In the tenth satire of the first book of Horace, the inhabitants are called *bilingues*, either from their duplicity, or, as is more generally believed, from their speaking Latin or Greek indifferently. The modern Canosa is built on the site of the ancient citadel of Canusium, and contains about 6000 inhabitants. Many interesting remains of antiquity are from time to time discovered in the neighbourhood.

CANUTE, or Knut, king of England, was the son of Sweyn, king of Denmark, whom he succeeded A.D. 1014, and, by the conquest of England, was the first monarch that united in his own person the undivided sovereignty of the two kingdoms, after the assassination of Edmund Ironside by Edric the brother-in-law of Canute, in 1017. He married Emma, widow of King Ethelred, and put to death or banished several persons whose legitimate claims to the throne he had reason to dread. Having thus confirmed his power in England, he crossed over to Denmark, in order to resist the attacks of the king of Sweden; and he carried along with him a great body of English under the command of Earl Godwin. This nobleman had there an opportunity of performing a service by which he both reconciled the king's mind to the English nation, and gained to himself the friendship of his sovereign. He was stationed next to the Swedish camp; and observing a favourable opportunity, he suddenly attacked the enemy in the night, drove them from their trenches, threw them into disorder, and obtained a decisive victory. Next morning, when Canute saw the English camp entirely abandoned, he imagined that the troops had deserted to the enemy; but was agreeably surprised to learn that they were then engaged in pursuit of the discomfited Swedes. He was so pleased with this success, and the manner of obtaining it, that he bestowed his daughter in marriage upon Godwin.

In another visit to Denmark, Canute attacked Norway, and expelled the just but unwarlike Olaus from his kingdom, of which he took possession. Canute, who was become one of the greatest sovereigns in Europe, now began to feel the unsatisfactory nature of worldly greatness; and, weary of the glory and turmoils of this life, he began to turn his thoughts upon that which is to come. Unfortunately the spirit which prevailed in that age gave a wrong direction to his devotion; and, instead of making atonement to those whom he had formerly injured by his acts of violence, he devoted himself to those exercises of piety which monkish superstition represented as most meritorious. He built churches, endowed monasteries, enriched ecclesiastics, and bestowed revenues for the support of chantries at Assington and other places, where he appointed prayers to be said for the souls of those who had there fallen in battle against him. He even undertook a pilgrimage to Rome, where he sojourned a considerable time; and, besides obtaining from the pope some privileges for the English school erected there, he engaged all the princes through whose dominions he passed to desist from those heavy impositions and tolls which they were accustomed to exact from English pilgrims. By this spirit of devotion, no less than by his equitable and politic administration, he gained the affections of his subjects.

A well-known and beautiful story shows that he had learned to bear his honours meekly. Some of his courtiers, desirous of serving their own interests by flattering their royal master, extolled his greatness as if nothing were now too great for him to resist or overcome. The monarch, it is said, caused his chair to be placed at the sea-side when the tide was flowing; and when the waves approached his feet, he, with a feigned assumption of that power which his obsequious attendants declared his own, commanded the rising waters to respect the voice of him who was lord of the ocean, and retire. The result was a practical rebuke to those sycophants, and, on the part of Canute, a humble ascription of omnipotence to God alone. From that time, it is said, he never would wear a crown. He died at Shaftesbury, A.D. 1036, in the twentieth year of his reign, and was buried in the monastery at Winchester.

CANVAS (French *canevas;* Greek *καννaβις*, hemp); a strong kind of cloth made of hemp or flax, and used for tents, sails, &c. Also a clear unbleached cloth, woven regularly in little squares used for working tapestry with the needle.

Canvas, among painters, denotes the prepared cloth on which pictures are drawn.

Canevas, among the French, signifies also the rough draught of the words to which an air or piece of music is composed, and which serves merely to indicate the measure and style of writing required of the poet who is to complete the work.

CANY, a town in the department of the Lower Seine, in France, with 240 houses and 1650 inhabitants.

CAOUTCHOUC, sometimes called *Gum-elastic*, or more commonly, from its use in removing pencil-marks from paper, *India-rubber*, is a substance *sui generis*, found in the milky juice of a great variety of tropical trees; the most prolific in this remarkable product being *Siphonia Cahuchu* or *Hevea guianensis*, *Urceola elastica*, and *Ficus elastica*. The first of these trees, which affords the best commercial caoutchouc, extends over a vast district in central America; the second is abundant in the islands of the Indian Archipelago; and the *Ficus elastica* abounds in Assam, and is plentifully distributed over some other parts of India. This substance is contained also in small quantity in the milky juices of some European plants.

Though caoutchouc was introduced into Europe early in the last century, its origin was unknown till 1736, when M. de la Condamine communicated to the French academy the discovery that it was the inspissated juice of a Brazilian tree, known by the native name of *Hhevé*. The best caoutchouc is still imported from Para, where it is called *borracha* and *seringa;* but the native name is *cahuchu*—and thence the word caoutchouc is derived. It is procured by piercing the tree, or by making a series of incisions around the trunk and main branches, whence the juice exudes abundantly as a creamy-looking fluid, which gradually becomes firmer and darker by exposure to the air. It is usually collected in clay cups, or in leaves folded in that form, and attached to the tree in the line of incision. It is also spread in successive layers on moulds of clay, which are crushed and shaken out when the process of drying is completed. In this manner the India-rubber bottles and figures of animals are produced. The trees are most prolific during the rainy season. The caoutchouc proper may be separated from the thinner portion of the juice by the application of heat, which coagulates it; and the same result is obtained by means of acids and with alcohol. The Indians have long been acquainted with the fact that cloth imbued with this juice is rendered impervious to water. They also form it into boots; and for this purpose they employ wooden lasts coated with clay, which are dipped from time to time in the fluid caoutchouc until they have received a coating of the thickness desired. To accelerate the process, the caoutchouc is usually dried over wood fires, and thus is blackened by the smoke. While still soft, it is frequently ornamented by indenting patterns on its surface, which its want of elasticity in that state enables it to retain very readily.

Caoutchouc is occasionally imported in its fluid state; but in spite of the utmost care to exclude it from the atmosphere it gradually tends to solidification. Fluid caoutchouc has the consistence and colour of cream, and a specific gravity of 1·012. In some recent experiments on caoutchouc juice, Dr Ure found one sample, with a specific gravity of 1·04125, to yield 20 per cent. of solid caoutchouc; while another of a thicker consistence, and a specific gravity of only 1·0175, yielded no less than 37 per cent. of white, solid, and very elastic caoutchouc. The ordinary commercial caoutchouc is in the form of bottles, solid balls, and crude masses, and varies considerably in quality according to the species of tree from which it is obtained, independently of adulteration by the admixture of earthy and other matters. Previous to being used for manufacturing purposes, the caoutchouc is freed from from its impurities by washing in warm water. Sometimes the masses contain a viscid tarry-looking matter (the result apparently of putrefactive fermentation), which renders them worthless.

Pure caoutchouc is insipid, with little if any perceptible odour, and has a specific gravity of 0·925. Unlike most solid vegetable products, it contains no oxygen. Its constituents, according to Professor Faraday, are carbon 87·2, hydrogen 12·8; while Dr Ure gives the result of his experiments as carbon 90, hydrogen 10, or three atoms of the former to two of the latter. Caoutchouc is insoluble in water, alcohol, and acids; but it dissolves more or less readily in ether, naphtha, coal-tar naphtha, bisulphuret of carbon, and some essential oils, as oil of cassafras, lavender, and turpentine. By certain processes it may be dissolved in the fixed oils; but these solutions when spread as varnishes remain in a glutinous state. One of the most perfect solvents for manufacturing purposes is a mixture of 100 parts of sulphuret of carbon and 6 or 8 parts of anhydrous alcohol. Caoutchouc is but slightly affected by the acids at the ordinary temperature; nor will the strongest caustic potash ley, even at a boiling temperature, dissolve it. Sulphuric acid, especially with the aid of heat, decomposes it; and so will nitric acid, if concentrated. Azotic acid changes it into a yellow insoluble substance, with the disengagement of a minute quantity of oxalic acid. From its quality of resisting the action of the most corrosive gases, tubes of this substances are much employed in the chemical laboratory; and it also forms, when fused, a very adhesive and efficient lute. When boiled in water it swells; and in this state it is more readily soluble in its several menstrua. Boiling water also renders it somewhat adhesive; so that a slip coiled about a cylinder, and held in position by a thread, may be formed into a tube. Its solutions in coal-tar naphtha and ether, when dried up, leave the caoutchouc unaltered in its properties. When treated with the first it soon swells to many times its original bulk; and the process of solution may be accelerated by trituration. This solution is much employed for rendering textile fabrics impervious to air and water, and formed the subject of Macintosh's well-known patent. For such purposes the manufacturers usually employ the coarse inelastic lumps and parings, which may be dissolved either in petroleum (coal-tar), naphtha, or oil of turpentine. The solution is effected in a close cast-iron vessel, by the aid of triturating cylinders; the heat generated during the process being alone sufficient to favour the solution Thirteen cwts. of caoutchouc may thus be prepared at one time in a vessel measuring 4 feet by 4; three days being required to complete the process. The quantity of caoutchouc much exceeds that of the solvent, so as to produce a varnish of considerable consistence. This

Caoutchouc.

solution is spread in one or more coats over the surface of the cloth; and in order to ensure its uniform thickness, the varnished cloth is drawn along under an edge or bar, which is placed horizontally to its surface, and almost in contact with it. When it is partially dry, another piece of cloth, similarly prepared, is applied carefully to the varnished surface of the first, and the two are then united firmly together by pressure between rollers. The cloth thus prepared is suspended in a well-ventilated stove-room, where it speedily dries, and loses in a great measure its offensive smell. When required for the purposes of the bookbinder, or any nice operation, this varnish should be well smoothed by rubbing, and then strained. The latter precaution, indeed, should be observed in the preparation of all caoutchouc varnishes, in order to remove the aloetic or other extraneous matter which usually occurs in the caoutchouc of commerce. To obtain the ethereal solution it is necessary that the ether be previously washed with water three or four times; and this purification may be simply effected by agitation with twice its bulk of water in a narrow-necked bottle, which is then to be inverted and allowed to remain in that position until the ether has separated and risen to the surface—when the water is to be drawn off. In this state the ether will completely dissolve it in the course of a few days. The caoutchouc should previously be cut into shreds, and boiled in water for two hours. For nice purposes this solution is particularly well adapted, as when spread it dries very speedily, leaving a coating of caoutchouc unaltered in its properties, and free from any disagreeable smell. It remains somewhat clammy for a while; but this defect may at once be removed by dusting its surface with sulphur or with French chalk. A varnish suitable for aerostatic machines may be obtained by digesting one part of caoutchouc, cut into shreds, in thirty-two parts of rectified oil of turpentine, and then straining the solution through muslin. A good transparent cement, too, for uniting small pieces of glass, &c., is said to be obtained by dissolving from fifteen to twenty grains of caoutchouc in two ounces of chloroform, and afterwards adding half an ounce of mastic; the whole to be allowed to macerate for a week, when it will be ready for use, and may be applied cold with a brush.

The most remarkable property of caoutchouc is its elasticity, which exceeds that of any other known substance. Cold and quiescence render it hard and rigid, but warmth speedily restores its elasticity. If a slip of this substance be softened by immersion in hot water, it may be extended to seven or eight times its length, and will contract very nearly to its original dimensions. Its expansive power may be strikingly exhibited in a very simple manner. If an India-rubber bottle be steeped in well-washed sulphuric ether till it has become quite flaccid, it may be expanded by means of a condensing syringe to a globe five or six feet in diameter. If suffered to dry in this state, its tractile power will be destroyed.

The great variety of purposes to which its elasticity and imperviousness to water and to air have occasioned its application, are too numerous and familiar to be particularized in this place. The extent of its employment in Britain in the several branches of manufacture is shown by the quantity of caoutchouc imported, which for the year ended January 5, 1854 amounted to 17,326 cwt. The total quantity exported from Para alone in 1852 was 32,860 cwt., and 116,465 pairs of shoes. The filature of caoutchouc, for the manufacture of elastic fabrics, such as cloth, cord, tape, braces, &c., is an important and increasing branch of our national industry. This operation has been made the subject of various patents, all modifications more or less perfect of one general principle, namely that of reducing it to threads by means of steel edges acting either on the bottle caoutchouc compressed in a mould, on the solid cake, or by cutting it when stretched on a mandrel of wood which is set in rapid revolution. In this operation water is allowed to trickle over the cutting blades in order to prevent the cohesion that would otherwise impede their progress. In this manner, thread of 5000 yards to a pound weight is produced. Previous to its employment in the manufacture of textile fabrics, it is necessary to render the thread inelastic; which is effected by winding it tightly on reels, and allowing it to remain in that condition until nearly deprived of its elasticity—which is afterwards restored by exposing it to the action of a heated smoothing-iron. Sheets are sometimes cut from the solid cake; and may likewise be obtained of any size, and of extreme tenuity, by spreading a solution in naphtha upon cloth previously sized, stripping it off when dry. The use of rollers, with a piece of cloth similarly prepared and superimposed on the varnished surface of the first, may also be employed in this operation.

Caoutchouc ‖ Cap.

An ingenious application of the elastic force of caoutchouc has been used to raise weights by what are called power purchases; and it has also been used as torsion springs for roller-blinds, for door-springs, as a projectile force, and a great variety of other purposes.

Caoutchouc when impregnated with sulphur—a process technically called *vulcanizing*—undergoes a very important change. Thus prepared, it becomes more uniformly elastic, always recovering its form after being stretched, and remaining unaffected by climatic temperatures. Various methods for effecting its sulphuration in the most effectual way have been proposed and patented. This may be done, either by adding sulphur to the naphtha or turpentine in which the caoutchouc is to be dissolved; by kneading in by means of a roller-press the flowers of sulphur, in the proportion of ten pounds of sulphur to sixty pounds of caoutchouc; or by impregnating it with the fumes of sulphur or its compounds. Sheets and tubes are well vulcanized by immersion for a few minutes in a mixture of 100 parts of sulphuret of carbon and 2½ parts of protochloride of sulphur, and then rinsing them in water. Other methods also are practised.

Caoutchouc burns with a bright flame, emitting much smoke, and an odour that is scarcely disagreeable. At a temperature of 248° Fahr. it fuses, and remains very long in a glutinous state. When exposed to about 600°, it resolves itself into a vapour which is condensable into a powerfully odorous and extremely volatile amber-coloured oil, which has received the name of *caoutchoucine*. Caoutchoucine is a powerful chemical solvent; and as when mixed with alcohol it dissolves copal and other resins without the aid of artificial heat, it is peculiarly useful in the preparation of varnishes. It is also a solvent of caoutchouc. By repeated rectification, this dark-coloured fluid becomes bright and transparent; and it may be deprived of its peculiar odour by being mixed and shaken up with nitromuriatic acid, or with chlorine. Though the lightest of known fluids, its vapour is so ponderous that it may be poured like water from one vessel to another. This interesting fluid is the discovery of Mr William Henry Barnard of Greenwich, who obtained a patent for it in 1833.

It is worthy of remark, that in the operation of grinding or kneading the crude masses of caoutchouc for the purpose of reducing the separate fragments into a homogeneous whole, the alternate expansion and contraction of the mass occasions so great an evolution of caloric that the water employed in the process, though cold as it trickles into the drum, is quickly raised to a boiling temperature.

For some very interesting details of the several processes connected with the manufacture of caoutchouc, the reader is referred to the article Caoutchouc in Ure's *Dictionary of Arts and Manufactures*, from which the leading facts here noticed are derived. (T. S. T—L.)

CAP, a cover for the head. Caps and hats were not in general use before the year 1449, the fashion having been introduced, it is said, at the entry of Charles VII. into

Rouen; from which time they began to take the place of the hoods or chaperons, which had till then been used. When the cap was of velvet it was called *mortier;* when of wool, simply *bonnet.* None but kings, princes, and knights, were allowed the use of the mortier. The cap was the head-dress of the clergy and graduates. Pasquier says that it was a part of the hood anciently worn by persons of the robe, from which the skirts were cut off as an encumbrance, leaving the round cap a convenient cover for the head; and when the round cap was afterwards assumed by the people, those of the gown changed it for a square one, first invented by a Frenchman named Patrouillet. He adds, that the giving of the cap to students in the universities denoted that they had acquired full liberty, and were no longer subject to the control of their superiors; in imitation of the ancient Romans, who gave a *pileus* or cap to their slaves, in the ceremony of making them free; and hence the proverb, *Vocare servos ad pileum.* Hence, also, on medals, the cap is the symbol of liberty.

The Romans for many ages had no regular covering for the head. As a defence against the rain or sun, the lappet of the gown was thrown over the head. The same usage obtained among the Greeks, at least during the heroic age; yet hats or bonnets appear in the Panathenaic procession.

The French clergy wear a shallow kind of cap called *calotte*, which only covers the top of the head, and is made of leather, satin, worsted, or other stuff. The red cap is a mark of dignity, allowed only to cardinals. The secular clergy are distinguished by black leathern caps; the regulars, by knit and worsted ones.

Churchmen, and the members of most universities, students in law, physic, and others, as well as graduates, wear square caps. In many universities doctors are distinguished by peculiar caps, which are given them on assuming their degree. Wickliff calls the canons of his time *bifurcati*, from their caps. Pasquier observes that in his day the caps worn by churchmen and others were called square caps, though in fact they were round yellow caps.

The cap is sometimes used as a mark of infamy. In Italy generally the Jews are distinguished by a yellow cap, but at Lucca by an orange one. Formerly in France, bankrupts were obliged to wear a green cap, that others might be warned against trusting them. By several arrêts in 1584, 1622, 1628, and 1688, it was decreed, that if such person were found without his green cap, his protection should be null, and his creditors might cast him into prison.

CAP *of Maintenance*, one of the regalia, or ornaments of state, carried before the sovereigns of England at their coronation and other great solemnities. Caps of maintenance are also carried before the mayors of some cities, and likewise appear in heraldic bearings.

CAPACITY, the power of containing or holding; extent of room or space. It is also applied to the extent or comprehensiveness of the intellectual faculties; and it likewise denotes state, condition, character, profession, occupation, &c. In geometry it signifies the solid contents of any body: in chemistry, that state, quality, or constitution of bodies by which they absorb and contain, or render latent, any fluid.

CAPALUAN, one of the Philippine Islands, fourteen miles in length by five in breadth. It lies about four miles south of the island of Luzon. E. Long. 121.48., N. Lat. 13. 50.

CAPARASON, or CAPARISON, the cloth or covering laid over a horse, especially a sumpter horse, or horse of state. The word is Spanish, *caparazon*, probably an augmentative of *capa*, a cloak. The ancient caparason was defensive armour with which horses were protected in battle.

CAPE, a high land running out with a point into the sea; as Cape Nord, Cape Horn, the Cape of Good Hope, &c.

CAPE-BRETON, an island of British America, to the north of Nova Scotia, from which it is separated by the Strait of Canso. It lies between 45. 27, and 47. 5. N. Lat. and between 59. 40. and 61. 40. W. Long. It has an area of about 2,500,000 acres, of which about one-third consists of swamps and barren wastes. It is deeply indented in all directions by arms of the sea, the largest of which, the great Bras d'Or, nearly divides the island in two, and being deep enough for the largest vessels, affords the greatest facilities for commerce. It was discovered by Cabot, but was first occupied by the French, in whose possession it remained till 1758, when it fell into the hands of the English. By them it was annexed to Nova Scotia and erected into a county, returning two members to the assembly. It was afterwards constituted a distinct government; but in 1820 it was re-annexed to Nova Scotia, to whose laws it has since remained subject. It now returns two members to the assembly. Population of the united county of Cape Breton and Victoria in 1851, 27,580. The climate of Cape Breton is very variable. In winter the thermometer sometimes falls to 32° and generally to 20° below zero; while in summer it rises to 96° in the shade. The mean summer heat may be estimated at 80°. The commercial resources of the island consist chiefly in its timber, its agricultural productions, its minerals, and fisheries. In the timber trade it joins with the mainland of North America in the shipment of pine, birch, ash, &c., to the United Kingdom. The agricultural produce consists chiefly of grain crops: the most extensively cultivated are oats (1,384,437 bushels), wheat (297,157 bushels), and barley (196,097 bushels), in 1851. On the pasture grounds horses and cattle are reared, and cheese and butter are made. The only minerals wrought in the island are coal, limestone, and gypsum; although iron ore and slate might be made available for commercial purposes. The coal mines are wrought in the neighbourhood of Sydney, and in 1851 yielded 53,000 chaldrons. In the same year the consumpt of limestone was 4421 casks. Gypsum is exported, although in very small quantity, to the United States. The fisheries, which employ nearly 1300 men, consist chiefly of salmon, cod, mackerels, herrings, shad, and white fish, of which large quantities are cured and exported. The rest of the population are engaged at the saw-mills, grist-mills, and tanneries, and in the manufacture of coarse cloth, flannel, and soap. The number of schools in the island in 1851 was 70, with an attendance of 2179 scholars. The number of churches in the same year was 47. The principal religious sects are, Roman Catholics 11,493; Free Church, 8968; Church of Scotland, 3452; Church of England, 2156; the rest consist of Methodists, Congregationalists, Baptists, &c. There is still a remnant of the native Indian population.

CAPE Clear. See CORK COUNTY.

CAPE Coast Castle. See COAST.

CAPE Fear River. See CAROLINA, NORTH.

CAPE of Good Hope. See GOOD HOPE.

CAPE Haytien, a seaport-town of the island of Hayti, on its northern coast, 90 miles north of Port-au-Prince, in N. Lat. 19. 46. W. Long. 72. 14. Pop. probably from 12,000 to 16,000. This town was formerly the capital of the island, and previous to the Haytian revolution was noted for its elegance and beauty, but is now remarkable for little more than the ruins of its former grandeur. It has a secure harbour protected on the north by a projecting tongue of land, but the entrance is rather difficult. It carries on a considerable trade, principally with the United States.

CAPE Horn. See HORN.

CAPE Verd. See VERD.

CAPEL, LORD ARTHUR, was the son of Sir Henry Capel. In 1640 he was chosen to represent the county of Hertford, and sat as a member of the Long Parliament, which was convened that year. He was elevated to the peerage by Charles I.; and on the breaking out of the revolution he

raised and maintained a troop in the royal interest till the final triumph of the Parliamentarians compelled him to make peace with them. He then retired to his private residence at Hadham. On reassembling his troop, in order to effect the rescue of Charles, he was forced to surrender at Colchester to General Fairfax, and was condemned by the Commons to be banished; but on the authority of some of the parliamentary leaders he was immediately committed to the Tower. He contrived to effect his escape from prison, but was apprehended at Lambeth, and again committed to stand his trial at Westminster for treason. He was condemned to death, and executed on the 9th of March 1649, exhibiting on the scaffold the greatest calmness and dignity. While in the Tower he wrote several stanzas, which were afterwards published. He was the author of *Daily Observations or Meditations, divine, moral, and political, written by a person of honour and piety; to which are added, Certain Letters written to several persons*, a posthumous publication, which was afterwards reprinted under a different title, with an account of his life.

CAPELL, Edward, the well-known critic and annotator of Shakspeare, was born at Troston in Suffolk in 1713. Through the influence of the Duke of Grafton, he was early appointed to the office of deputy-inspector of plays, with a salary of L.200 per annum. Shocked at the inaccuracies which had crept into Sir Thomas Hanmer's edition ot Shakspeare, he projected an entirely new edition, to be carefully collated with the original copies. After spending three years in collecting and comparing a vast number of scarce folio and quarto editions, he published his own edition in 10 vols. 8vo, with an introduction, which was written in a style of extraordinary and romantic quaintness, and which was afterwards appended to the prolegomena of Johnson's and Steevens's editions. The work was published at the expense of the principal booksellers of London, who gave him L.300 for his labour. Three other volumes of *Notes and various readings of Shakspeare*, which he had announced in his introduction, under the title of *The School of Shakspeare*, were published under the editorial superintendence of Mr Collins, in 1783, two years after Capell's death. They contain the results of his unremitting labour for thirty years in collating the ancient MSS., and throw considerable light on the history of the times of Shakspeare, as well as on the sources from which he derived his plots. Besides the works already specified, he published a volume of ancient poems called *Prolusions*, and an edition of *Antony and Cleopatra* adapted for the stage.

CAPELLA, Martianus Mineus Felix, a celebrated writer, who lived somewhere about the close of the fifth century A.D. From his familiar name of *Afer Carthaginiensis*, he appears to have been born at Carthage; but of his life nothing is known with certainty. He is the author of a voluminous allegorical work entitled *Satyra de Nuptiis Philologiæ et Mercurii*, in nine books, which attained a wide celebrity during the middle ages. It is a medley in prose and verse, composed in the bizarre style of Varro's *Satyra Menippea*, and Petronius's *Satyricon*, and probably furnished the model of Boethius' *Consolatio Philosophiæ*. The first two books give an account of the nuptials of Mercury with Philology, mentioned in the title, and the remaining seven are devoted to an exposition of the seven liberal sciences, grammar, dialectics, metaphysics and logic, rhetoric, geometry, arithmetic, astronomy, and poetry. In the eighth book he makes the remarkable assertion that the earth is not the centre of all the planets, but that Venus and Mercury revolve in common round the sun; and it seems probable that Copernicus, who quotes Capella (*De revolutionibus orbium cœlestium*, lib. i., cap. 10), derived from this the first hint of his system. The whole work is one which displays immense learning, and, independently of its African idioms, probably owes much of its barbarous appearance to the frequent erroneous transcriptions which were made by the monks for the use of the mediæval schools. The best editions are those of Hugo Grotius, 8vo, Leyden, 1599, and U. F. Kopp, 4to, Frankf., 1836.

Capella, a bright fixed star in the left shoulder of the constellation Auriga.

CAPELLUS or CAPPELLUS, Ludovicus, a celebrated Protestant theologian, born at Sédan in France, abou the year 1579. After prosecuting his studies at Sédan, Oxford, and Saumur, he was appointed Professor of Divinity and Oriental languages in the University of Saumur, and wrote several learned critical and exegetical works. He is chiefly known from his controversy with the younger Buxtorf, in regard to the antiquity of the Masoretic pointing, which had been first called in question by Jacob Perez of Valencia, in his Commentary on the Psalms. His book *Arcanum punctationis revelatum* was written in reference to a passage in the *Tiberias* (viii. 8.) of the elder Buxtorf, and was answered in the *De punctorum origine, &c.* of the younger, in reply to which Capellus again published his *Vindiciæ arcani punctationis revelati*. The arguments which Capellus advanced from the existence of unpointed MSS., of unpointed alphabets, and unpointed quotations in Origen, Jerome, and the translators generally, have been confirmed by the researches of modern Hebraists, who have shown that the present elaborate system of pointing cannot be traced beyond the eleventh century. Capellus died about the year 1658. His brother James was also distinguished as a theologian and an astrologer.

CAPERCAILZIE, the Scotch name for the capercail or wood-grouse, which had ceased to hold a place in the British fauna, until lately re-introduced with success by Lord Breadalbane. It is the *Tetrao Urogallus* of Linnæus.

CAPERNAUM (Καπερναούμ), a city on the northwestern side of the Lake of Gennesareth, and on the border of the tribes of Zebulun and Naphtali. The infidelity and impenitence of the inhabitants, after the evidence given to them by our Saviour himself of the truth of his mission, brought upon them this heavy denunciation:—"And thou, Capernaum, which art exalted unto heaven, shalt be brought down to hell," &c. (Matt. xi. 23.) This seems to have been more than any other place the residence of Christ after he commenced his mission; and hence the force of the denunciation, which has been so completely accomplished, that even the site of Capernaum is quite uncertain. Dr Robinson regards its site as marked by a mound of ruins, called by the Arabs Khan Minyeh, situated in the fertile plain on the western border of the Lake of Gennesareth. In this plain Josephus places a fountain called Capharnaum: he says nothing of the town; but, as the town of Capernaum was in this same plain, it may be safely concluded that the fountain was not far from the town, and took its name therefrom. In this plain there are now two fountains, one called 'Ain el Madauwarah, the "Round Fountain," rising immediately at the foot of the western line of hills; the other, called 'Ain et-Tin, near the northern extremity of the plain, and not far from the lake. This latter fountain Dr Robinson inclines to regard as that which Josephus mentions under the name of Capharnaum. Near it is a low mound of ruins occupying a considerable circumference, which are most probably the remains of the doomed city: and if these be all its remains, it has, according to that doom, been brought low indeed. It is important to add, that Quaresmius expressly states, that in his day, the place called by the Arabs Minyeh, was regarded as marking the site of Capernaum.

CAPEROLANS, a congregation of the minor order of Observants, in Italy, so called from Peter Caperole their founder, in the fifteenth century.

During the Milanese and Venetian war, the superiors in the province of Milan, whose jurisdiction extended as far as Venice, behaved so haughtily to the Venetians, that the

monks of Brescia resolved to shake off their yoke. The superiors, informed of this, drove out of the province those whom they considered as the authors of the plot, the principal of whom were Peter Caperole, Matthew de Tharvillo, Gabriel Maluezzi, and Bonaventure of Brescia. Peter Caperole, with a view to separate the convents of Brescia, Bergamo, and Cremona, from the province of Milan, instituted a law-suit against the vicar-general, which was determined in his favour; and the convents, in 1475, by the authority of Pope Sixtus IV., were erected into a distinct vicarate. Soon after, by the interposition of the doge of Venice, this vicarate was erected into a congregation, which from him was called *Caperolans.* On the death of Caperole, they were incorporated with the Observantine order, but retained a separate jurisdiction, under the title of the Province of Brescia. They consist of about twenty-four convents in Brescia, Bergamo, Cremona, and other places.

CAPERS, the pickled buds or unexpanded flowers of *Capparis spinosa*, which grows in the warm parts of Europe.

CAPH, a Jewish measure of capacity for things, estimated by Arbuthnot at the sixteenth part of the hin, or five-eighths of an English pint.

CAPIAS, in *English Law*, is a name given to certain executive writs. It is derived, according to a common practice, from the initial words in the order or instruction. This writ is of two sorts; one before judgment in an action, and the other after. That before judgment is called *capias ad respondendum*, and may issue, at any time before final judgment, on the application of a plaintiff having a cause of action to the amount of L.20 or upwards (1st and 2d Vict., c. 110) against a defendant who it is suspected is about to quit the country. Under this writ, the defendant is arrested, and cannot obtain his discharge until he gives bail, or deposits the amount of the debt, together with L.10 for costs. That after judgment is of divers kinds; as,

Capias ad Satisfaciendum, abbreviated into *ca. sa.*, is a writ authorizing execution by imprisonment, and its use has of course been much restrained by recent legislation. It issues on a judgment obtained, and lies where any person recovers in a personal action, as for debt, damages, and the like, exceeding L.20, exclusive of costs (7th and 8th Vict., c. 96).

Capias pro Fine was anciently a writ lying where a person was fined to the king for some offence committed against a statute, and who did not discharge the fine according to the judgment. So early as the 5th and 6th Will. and Mary, c. 12, it was abolished in cases of trespass, ejectment, assault, and false imprisonment.

Capias ut Lagatum, is a writ which lies against any one outlawed in any action, by which the sheriff is ordered to apprehend the party outlawed, for not appearing on the exigent, and keep him in safe custody till the day of return, when he is ordered to present him to the court, to be there further dealt with for his contempt.

Capias in Withernam, generally employed against a party endeavouring to evade distress or execution against moveables, is said to lie for goods *in withernam;* that is, where the distress is carried out of the county, or concealed, so that the sheriff cannot make deliverance upon a replevin. The writ requires the sheriff to take other goods of the distreinor, in lieu of the distress formerly taken, and withheld. The term *withernam*, in the old northern languages, is used as equivalent to *reprisals*. Under the new County Courts Act, 9th and 10th Vict., c. 95, the law on the subject of the replevin of goods taken in withernam is materially altered.

The process for treason or felony is also in general by writ of capias, 25th Edw. III., c. 14; and it may also issue on indictments for misdemeanour; but the more usual mode is by a bench warrant, signed by a judge or by two justices, under the 48th Geo. III., c. 58, sec. 1, and the 11th and 12th Vict., c. 42, sec. 3.

CAPIDJI, in Turkish, signifies literally a doorkeeper. The term, however, is applied not only to the porters of the seraglio, but also to those functionaries who are sent into the provinces to administer justice, and who frequently, under the pretence of being the bearers of presents and similar marks of the imperial favour to the pachas and other great personages, are commissioned to put them to death.

CAPILLARY (from *Capillus*, hair) resembling a hair, fine, minute, small in diameter though long.

CAPILLARY ACTION.

1. When a solid body is partially plunged in a fluid, the level surface near it is disturbed, and the fluid is observed either to ascend or descend, so as to form a ring round the part immersed. If a tube of glass be inserted in a vessel containing water, the liquid will rise in a concave ring, both on the outside and the inside; and if the tube be small enough, the cylinder of water within it will be elevated above the general level, and the elevation will be greater nearly in the same proportion that the bore is less. On the other hand, if the tube be plunged in mercury, the fluid in contact with the glass will be depressed, forming a hollow ring with the convexity upward; and when the diameter is very small, the cylinder of mercury in the inside will sink below the level on the outside. In all these appearances the physical cause is the same, and it has received the name of Capillary Action, because its effects are most remarkable in the case of tubes with extremely minute diameters.

No part of natural philosophy has been the subject of a greater variety of researches than capillary action. It has been viewed in almost every possible light, and it would be difficult to suggest a new principle that has not been proposed by some philosopher in order to account for the observed appearances. One advantage has resulted from repeated discussion; for by this means the true cause of the phenomena is no longer doubtful, although there is still considerable difference of opinion with regard to the manner in which the effects are produced. It is now universally allowed, that the suspension of fluids in capillary tubes is to be ascribed to the attraction observed to take place between the elementary particles of which bodies are composed. We shall not stop to detail the different experiments which prove the reality of this attractive force, and we shall at once assume that the two following facts, which are the fundamental principles of this theory, are fully established; namely, that glass and other solid bodies attract the particles of fluids with which they are in contact, and that the particles of fluids attract one another. Admitting these two kinds of attraction, it remains to investigate the consequences that flow from them.

2. Corpuscular attraction acts with great intensity in contact, or at the nearest distances, but it decreases very rapidly as the distance increases, and, on the whole, is confined within a very small range. Clairaut supposed that the sides of a capillary tube extend their action to the central parts of the contained cylinder of fluid. But in this opinion he is singular. All other philosophers confine the sphere of attraction within much narrower limits. They suppose that the corpuscular force has produced its full effect, and has become evanescent, at a distance so small that it cannot be appreciated by the senses. But

Law of corpuscular attraction.

from this we are not to conclude that a particle attracts those only which are quite contiguous to it; its action, although confined within a sphere of a very small radius, nevertheless extends to some distance, and reaches to the particles beyond the nearest.

As corpuscular attraction extends its influence to a distance, it must vary, within the sphere of its action, according to some law, which is unknown, and in all probability will never be discovered. But a knowledge of this law is not necessary to explain the capillary phenomena; for these are caused by the accumulated action of the force in its whole range, and are independent of the intermediate variations of intensity which it may undergo. In this respect capillary action resembles the attraction by which transparent bodies refract the rays of light. In both cases, what we observe is the total effect of the attractive energy, which may remain the same, although the intermediate degrees of intensity be infinitely varied.

3. Conceive a fluid mass (Plate CLVII. fig. 1), the particles of which attract one another, but which is subjected to the action of no other forces, not even to that of gravity; and let an imaginary surface be traced through the fluid, having at every part a depth equal to the utmost range of the corpuscular force. Then a particle placed within the imaginary surface may be considered as occupying the centre of a sphere of the fluid, described with a radius equal to the greatest distance to which attraction reaches; whence it is manifest that the particle will be urged with equal forces in all opposite directions. If the particle be placed between the boundaries of the superficial stratum or film, the sphere of which it is the centre will extend above the fluid's surface; and, on account of the defect of matter, the particle will be less attracted outward than inward. Let N be a particle so situated, and suppose that *n* is another particle as much elevated above the fluid's surface as N is immersed below it; and trace the surface PQ in the fluid as far below N as that particle itself is below the outer boundary of the fluid mass. Then the particle N will be in equilibrium with regard to the attraction of all the fluid above PQ; but it will be urged inward by the force with which it is attracted by the fluid below PQ; and as the particles at N and *n* are similarly situated with regard to the whole fluid mass, and the part of it below the surface PQ, it is manifest that the attraction of the whole mass upon the particle at *n* is equal to the force which urges the particle at N inward. From this it follows, that all particles placed in a stratum which is everywhere at the same depth below the fluid's surface, are drawn inward with the same force, equal to that with which the whole mass attracts a particle placed at an equal height above the fluid's surface.

If now we conceive a canal passing through the interior of the fluid, and terminating both ways in the surface, it follows, from what has been said, that the attraction of the whole mass upon the superficial drops placed at the two orifices will propagate equal pressures in opposite directions through the canal. In order to estimate the force of compression, we may denote by K the pressure inward, caused by the attraction of the whole fluid upon a square inch of the superficial film; then a portion of the fluid within the canal will be compressed by the equal forces, K, acting in opposite directions. This is true of all portions of the fluid within the superficial stratum; between the boundaries of that stratum the compressive force is less, being always of the same intensity at the same depth, but decreasing rapidly in approaching the surface, where it is evanescent.

We may now conceive a fluid mass, whatever be its figure, to consist of a central part, surrounded by an indefinite number of thin beds or strata, placed at equal depths below the surface; and it will follow, from what has been proved, that the compression is constant in all the central part; and likewise that it is uniformly of the same intensity throughout every superficial stratum, varying from one stratum to another, and decreasing very rapidly near the surface. Such a body of fluid will therefore be in equilibrium whatever be its figure; in other words, the corpuscular attraction will oppose no resistance to a change of figure in the fluid, nor obstruct, in any degree, the perfect mobility of the particles among one another.

It must be observed, however, that the conclusion just obtained is exact only when we confine our attention to the direct action of the attractive forces, as is done in the theory of the figure of the earth. But there is another effect caused by the direct attraction of the particles of a fluid, to be afterwards considered, which takes place only at the surface, and from which this consequence results, that a body of fluid subjected to no forces but the attraction of its own particles will no longer be indifferent to any figure, but will arrange itself in a perfect sphere.

Effect of temperature.

A change in the temperature of a fluid mass will produce an alteration in the cohesive force; but it appears very difficult, if not impossible, to estimate, in any satisfactory manner, the effect arising from this cause.

A variation of temperature will affect the attraction of the particles of a fluid by the change of density which it induces. When two portions of a fluid attract one another, if we conceive one of them to have its density changed, while that of the other remains unaltered, it is evident that their cohesion will be proportional to the number of particles of the first portion placed within the sphere of action of the second; that is, it will vary in the direct proportion of the density. Again, if we now suppose the density of the second portion to vary, the attractive force will on this account also suffer a proportional change. Wherefore, when both portions undergo an equal change of temperature, their cohesion will vary as the square of the density.

Again, the variations in the mutual distances of the particles of a fluid, caused by changes of temperature, must bear a finite proportion to the range of the corpuscular force; and, on this account, a change in the fluid's cohesion will take place, depending upon the law that attraction follows in regard to the distance. At a given temperature, and under a given pressure, the particles are separated from one another to a certain distance, at which there is an equilibrium between the attractive force which impels them to one another, and the repulsive power attending the action of heat. In these circumstances, the actual cohesion is due to that part only of the whole corpuscular force which is exerted upon the particles placed beyond the limit of approach allowed by the given degree of temperature. The cohesion, too, is diminished not only by the decreased intensity of the attractive force, but also by the increased repulsion of heat. Our ignorance of the laws that regulate the action of these forces makes it impossible to subject to calculation the effect of a change of temperature; but, when we consider that corpuscular attraction decreases very rapidly as the distance increases, it is extremely probable that the cohesion of a fluid undergoes much greater changes from this cause than from the variations of density.

But capillary action arises from the cohesion between the particles of a fluid, and the attraction that takes place between them and the solid bodies with which they are brought into contact. Experiments show that these forces continue to act so long as the state of fluidity endures; their action is constant under the same temperature; and they are affected in degree only by the variations of heat. In the further prosecution of this inquiry we shall there-

Capillary Action.

fore throw out of view the effect of temperature, and shall confine our attention to develope the consequences of corpuscular attraction.

Attraction between a solid body and a fluid.

4. The attraction of a solid body on every particle of a fluid within the sphere of its action, is a force perpendicular to the surface of the solid. This is manifest from the homogeneity of the solid when its surface is a plane; for, on account of the uniform arrangement of the parts, there is no reason why the attractive force should decline from the perpendicular to one side rather than to another. And when the solid is bounded by a curve of any kind, we may still consider the extremely small part of the surface which acts on a particle, as coinciding with the tangent plane; whence we may conclude that, in all cases, the attraction on every particle is perpendicular to the surface of the attracting body. The same thing is true in the action of transparent bodies on light; for, if the motion of a ray be decomposed into two parts, one parallel to the refracting surface, and the other perpendicular to it, the observed law of refraction implies that the velocity of the first part will remain unchanged, while the velocity of the other part will be increased or diminished by the refracting force.

If a smooth plate of glass be laid horizontally upon the surface of water, it is found that the glass will adhere to the water. The adhesion is not produced by the pressure of the atmosphere, for the fact is equally true in the vacuum of an air-pump. There is, therefore, evidently an attraction between the glass and the water, acting perpendicularly to the plate, and causing it to adhere to the water.

If the plate, instead of being laid horizontally upon the water, be immersed vertically in it, the part below the surface will exert the same attractions as it did in the former position. Every particle of the fluid within the sphere of action of the glass will be drawn perpendicularly towards it, and a thin coating of the fluid will attach itself to all the immersed surface of the plate.

Secondary or lateral force.

5. Although the attractive force exerted by a solid body on a fluid is confined to insensible distances, it must still be considered as penetrating in some degree into the fluid mass. The thin film on which it acts retains possession of all the properties of a fluid. The particles of water in contact with the glass press upon its surface; the particles farther off press upon those nearer; and the whole film is in a state of compression. But it is a distinguishing property of a fluid, arising from the perfect mobility of its particles, that a pressure in one direction will cause an equal pressure in all directions; and hence we must infer that the thin film of water, at the same time that it is compressed by the direct attraction of the glass, will likewise press laterally, or will make an effort to spread itself towards every side on the surface of the plate. If the film, instead of being attracted by the plate, were pressed against its surface by a weight, the lateral pressure, estimated on a given superficial space, would be the same with the direct pressure. But as the strata at different distances from the plate are attracted in unequal degrees, the whole lateral force can be found only by summing up the lateral pressures arising from the attraction upon each stratum.

Let AB (fig. 2) be a plate of glass on which there stands an upright vessel or tube, containing water; and let GH be a thin section or elementary part of the water within the tube, parallel to the glass, and so near it as to be attracted by it. Suppose that w denotes the area of the section, a its distance from the plate, and da its thickness; and let $\Psi(a)$ represent the attraction of the whole matter of the plate upon a single particle of water placed at the distance a. Then the density being constant and equal to unit, the attractive force of the plate upon the thin elementary section will be equal to

$$\Psi(a) \times w da;$$

and hence the attraction of the plate upon all the water in the tube will be equal to the integral

$$w \times \int \Psi(a) \cdot da,$$

generated while a increases from 0 to be infinitely great. The expression $\int \Psi(a) \cdot da$, which we may denote by K′, is therefore the force with which the attraction of the glass causes the fluid to press upon a square inch of the plate, or it is the measure of that force. If the particles of the fluid were attracted by the matter of the plate with an intensity equal to their own cohesive force, then K′ would be equal to K, that is, it would be equal to the force with which an indefinite mass of the fluid causes the superficial stratum to press inward.

In the inside periphery of the tube, assume any determinate length ab, equal to λ, and let the lines ac, bd, be drawn in the interior surface at right angles to ab. The area of the space $abdc$ is equal to $\lambda \times a$; and because fluids press equally in all directions, the attraction which urges the elementary section towards the plate AB will cause the fluid below the section to press upon the space $abdc$ with a force which is to the attractive force urging the section downward, as $\lambda \times a$ to the area of the section. Hence the pressure on the space $abdc$, caused by the attraction of the glass on the elementary section GH, is equal to

$$\lambda \times \Psi(a) \cdot a da.$$

This expression would evidently denote the pressure upon the surface $abdc$, if the fluid below the section were impelled towards the plate by a piston exactly fitted to the orifice of the tube. But there is no difference between the action of such a piston and that of the thin elementary section when urged by attraction with equal force in the same direction. The total force acting laterally in the length λ, is therefore equal to the fluent

$$\lambda \times \int \Psi(a) \cdot a da,$$

generated while a increases from 0 to be infinitely great. Hence, if we put $H' = \int \Psi(a) \cdot a da$; then H′ will be the measure of the lateral force in the length equal to unit.

It is obvious that the direct attraction between two portions of a fluid, as well as that between a solid and a fluid, is attended with a lateral pressure. If we denote by H what H′ becomes when the matter of the plate attracts the fluid with the same intensity that the fluid attracts its own particles, then H will be the measure of the lateral force arising from the direct attraction of the fluid, and it will have the same relation to K that H′ has to K′.

The lateral force is always very small when compared with the direct pressure. For the function $\Psi(a)$ has a conceivable value only when a is so small as to be imperceptible to the senses; in such circumstances the product $\Psi(a) \times a$ is very small when compared with $\Psi(a)$; and, consequently, $H' = \int \Psi(a) a da$ is considerable in respect of $K' = \int \Psi(a) \cdot da$.

The smallness of the lateral in comparison of the direct pressure arises from this, that every elementary part of the latter is estimated on the same finite area, while the simultaneous element of the former is confined to a space incomparably less. These two pressures resemble the power in the hydrostatic paradox, and the effect which it produces. In both cases we have a small pressure applied

to a surface extremely minute, in equilibrium with a great pressure distributed over a comparatively large area.

When a piece of glass is partially plunged in water in a vertical direction, the thin film which is attracted by the immersed surface endeavours to spread itself on the glass with an effort more or less in proportion to the compressive force. Below the surface of the water the lateral actions of the parts in contact mutually counteract one another; but at the surface the expansive force meets with no opposition. The film will therefore be pushed above the general level; and as it acts by cohesion on the contiguous fluid, it will draw up a portion of it, and form a ring surrounding the immersed part of the glass. The small fluid mass on which the glass exerts its attraction performs the office of a machine, which changes a horizontal force into one having a vertical direction. In the mechanical properties of a fluid we thus have a principle adequate to account for what we observe in capillary action. But although the general view here given of the cause of the capillary phenomena is so far satisfactory, a great deal of discussion is still necessary, in order to deduce from it a clear explanation of the laws observed in the appearances that take place in different circumstances.

The idea of accounting for capillary action by means of the lateral force produced by the direct attraction of a solid body upon a fluid, is due to Professor Leslie, a philosopher to whom physical science is indebted for more than one discovery. It is developed and applied, to explain some of the principal phenomena, in a short dissertation published in 1802 in the *Philosophical Magazine*. This dissertation is written with the same ability that characterizes all the productions of the author; and nothing more was necessary than to pursue the observation he had made, in order to obtain a complete theory of this branch of natural philosophy. It happens that, in this instance, the views of the philosopher are confirmed by the most abstruse and refined mathematical investigation. The formula found by Laplace for the attractive force of a fluid bounded by a curve surface, consists of two parts, one of which is the same for all surfaces, and the other varies with the curvature in each particular case. The first of these terms is the attractive force of an indefinite mass of the fluid bounded by a plane. The other term, which depends upon the curvature, is composed of a constant quantity multiplied into half the sum of the reciprocals of the radii of the circles, which have the same curvature with any two sections of the curve surface made by planes, perpendicular to one another and to the curve surface; and, on examination, this constant quantity will be found to coincide with the measure of the lateral tendency of the fluid caused by the direct action of the first force. Thus it appears that the two quantities which enter into the formula of Laplace are no other than the measures of the two kinds of force which we have been considering; the one denoting the direct pressure caused by the attraction of a fluid mass bounded by a plane, and the other signifying the derivative force acting laterally, which is a necessary consequence of the direct pressure. In a subsequent part of this article, what has now been advanced will be proved, by deducing the formula of Laplace in a direct and satisfactory manner from the two kinds of force, with the consideration of which we have been occupied.

Manner in which the immersion of a solid body disturbs the equilibrium of a fluid.

6. Imagine a large vessel DGHF (fig. 3), which contains a fluid subjected to no forces but gravity and the attraction of its own particles, and consequently having its surface DF horizontal; let AB represent a rectangular plate partially plunged in the fluid which it attracts; and supposing the surface of the fluid to remain level, let it be proposed to investigate the force with which the attraction of the plate tends to disturb the equilibrium of the fluid.

Suppose a horizontal plane, *df*, to be traced in the fluid, at a depth equal to the range of the corpuscular force; then this plane will separate all the superficial strata, in which the pressure is variable, from the rest of the mass. Below the plane *df*, the fluid particles cohere with the same force in every part, and they are likewise attracted with equal intensity by all the points of the plate with which they are in contact; above the same plane the attractive force of the plate remains unchanged, but the pressure of the fluid in the different strata is variable, gradually becoming less and less as we approach the surface. It will therefore be proper, first to examine what tendency the part of the plate below the plane *d f* has to disturb the equilibrium; and, secondly, to consider the effect of the plate's attraction upon the superficial film or stratum.

If the matter of the plate have the same attraction for the particles of the fluid that they have for one another, we may consider the plate as a body of the fluid that has congealed without any other change; in which case it is evident that, below the superficial stratum, the cohesive force of the fluid particles will be equal to their adhesion to the plate, and the action of the solid matter will nowise disturb the equilibrium of the fluid in the vessel.

If the plate be supposed to have no attraction for the fluid, a canal having one end in the surface of the fluid, and the other end on the plate, will be similar to a canal terminating both ways in the fluid's surface. It will be in equilibrium by the mutual attractions of the particles within it, and will exert no pressure whatever upon the plate.

If the solid matter attract the particles of the fluid, but with less intensity than they attract one another, there will be an adhesion of the fluid to the plate in proportion to the attractive force. In this case we may distinguish the attraction between the fluid particles into two parts, one of which is equal to and in equilibrium with the attraction of solid matter; while the other part, which is over and above what balances the attraction of the solid matter, is in equilibrium by the mutual action of the particles upon one another.

The solid matter acts immediately upon a thin portion of the fluid in contact with it; that portion attracts another contiguous portion; and in this manner the attraction of the plate reaches to any distance in the fluid mass. But from this it is manifest that the whole of a force greater than the mutual attraction of the particles cannot be propagated to a distance. Part of it must remain confined to the sphere of immediate action. Hence, if the plate attract the particles of the fluid with greater intensity than they attract one another, a part only of the attraction of the solid matter will balance the whole attraction of the fluid; and the remaining part will not penetrate beyond the range of the corpuscular force, but will act only upon a thin film of the fluid in contact with the plate. In this case, therefore, the plate's attraction produces a force which is not absorbed by the fluid. As this force compresses the thin film on which it acts upon the plate's surface, it will be attended with a lateral pressure, or an effort of the film to spread itself on all sides; and it may at first be thought that this lateral tendency, by acting upon the superficial stratum, will disturb the equilibrium. But it will immediately occur, that the effort which the edge of the film adhering to the plate below the plane *df* makes to raise up the superficial stratum, is counteracted by the opposite effort of the fluid situated immediately above the plane *df*. Thus, in every relation that can subsist between the attractive powers of the plate and the

Capillary Action.

fluid, that part of the solid which is immersed below the superficial stratum has no tendency to disturb the equilibrium of the fluid in the vessel.

Insufficiency of Laplace's second theory of capillary action

Some philosophers account for capillary action by means of attractions between the plate and the fluid, which are supposed to take place, partly at the surface of the fluid, and partly at the bottom of the plate. Laplace, in particular, has grounded his second or more popular theory entirely on such attractions. He observes, that the part of the plate's vertical plane immersed in the water attracts the fluid in contact with it as much upward as downward, and therefore has no effect in causing either an elevation or a depression; but the part above the water attracts a thin film in contact with the plate upward; and the whole vertical side of the plate likewise attracts in the same direction the fluid below it, and situated in its prolongation. According to Laplace, it is the united effect of these two attractions which supports the suspended ring. The whole of this reasoning appears to us gratuitous. No part of the fluid is attracted by the solid matter in a vertical direction, but in a direction perpendicular to the plate's surface. The immersed part of the solid presents a continuous surface to the fluid, attracting it with the same intensity at every point; whereas Laplace neglects the action of the plate's horizontal boundary, and seems to suppose that the attractive energy of the solid matter resides only in the vertical sides. We have endeavoured to prove that the thin film or coating of fluid which covers the part of the solid immersed below the superficial stratum, is everywhere in a state of equilibrium and of equal compression by the attractions which act upon it. There is, therefore, no force produced at the bottom of the plate by the attraction between the solid matter and the particles of the fluid which can contribute to support the weight of the ring raised above the level.

We proceed now to consider the action of the plate upon the superficial stratum. Trace a canal at right angles to the plate, of the same depth with the superficial film, and having its horizontal width equal to unity, and continue the canal till it terminate in a vertical plane PS, parallel to the plate. Let n be the small portion of the canal within the sphere of the plate's attraction, and suppose the canal to be divided in its whole length into the parallelopipeds m, m, m, &c., each equal to n. It is plain that the attractions of the fluid below the canal, and on the two sides of it, have no tendency to impel it in any direction, nor to impede the motion of the fluid along it. The canal is also in equilibrium with regard to gravity, since by the hypothesis it is horizontal. The rectangular wedge of fluid beyond the plane PS will attract the small parallelopiped contiguous to it with a force proportional to $\frac{1}{2}$K, because K denotes the attractive force of two rectangular wedges, sect. 5; and the same parallelopiped will also be attracted with an equal force in the opposite direction by the one next to it. In like manner, every parallelopiped in the canal is attracted with equal forces by those contiguous to it on opposite sides, except the one in contact with the plate, which is attracted in the direction of the canal with the force $\frac{1}{2}$K, and towards the plate with the force K′, depending upon the intensity of the plate's attraction for the fluid.

Now, if K′ be just equal to $\frac{1}{2}$K, which will happen when the intensity of the plate's attraction is half that of the fluid, the parallelopiped n will be situated, with regard to the forces that act upon it, similarly to the others in the canal; in this case, therefore, the insertion of the plate will not disturb the equilibrium of the fluid, the surface of which will remain horizontal.

If K′ be greater than $\frac{1}{2}$K, it may be resolved into two parts, $\frac{1}{2}\text{K} + (\text{K}' - \frac{1}{2}\text{K})$, of which one will counterbalance the opposite force, and reduce the canal to equilibrium; and the other part, $\text{K}' = \frac{1}{2}\text{K}$, will act only upon the parallelopiped n, and will compress it upon the surface of the plate. The compression will produce a lateral force proportional to $\text{H}' - \frac{1}{2}\text{H}$, which urges the small fluid mass to spread itself towards every side; and as this force is unopposed vertically upward, the equilibrium of the fluid will be disturbed; the superficial film will ascend all round the plate, and, by means of the force of cohesion, will carry with it a portion of the fluid till the suspended weight is sufficient to counterbalance the force acting upward.

When K′ is less than $\frac{1}{2}$K, the parallelopiped in contact with the plate will be more attracted in the direction of the canal than towards the plate. When this happens the fluid is depressed below the level by capillary action; but we shall leave this case to be afterwards considered, and at present confine our attention to the former case, when the fluid is elevated above the level.

Ring upon the surface of a solid body plunged in a fluid.

7. When the immersion of the plate causes an elevation, the fluid will assume the form of a concave ring, as KLM (fig. 4). If we suppose a superficial canal divided into parallelopipeds as before, we may prove by like reasoning that the attraction of the solid matter has no tendency to disturb the equilibrium of the fluid except by the lateral force which it communicates to the small parallelopiped in contact with it. And since the attractive force of the plate upon the particles of the fluid depends only upon their perpendicular distance from its surface, it readily follows that the lateral force will undergo no variation, but will remain constantly equal to $\text{H}' - \frac{1}{2}\text{H}$, both during the rising of the ring, and when it has attained the greatest elevation. The reciprocal attraction of all the fluid in the vessel likewise produces pressures that are propagated inward from the surface of the fluid, and from the sides and bottom of the vessel, sect. 3; but these forces cannot be in equilibrium with the ring and the disturbing force arising from the plate's attraction. For the former forces have no tendency to move the centre of gravity of the whole mass, whereas the latter tend to produce motion in that point, each in its own direction. In the case of equilibrium, therefore, the vertical force arising from the plate's attraction must be equal to the weight of the suspended ring; or, which is the same thing, $\text{H}' - \frac{1}{2}\text{H}$ will express the weight of a portion of the ring in every unit of the horizontal extent.

The vertical force produced by the attraction of the solid matter begins to act the instant the fluid comes into contact with the solid; it first causes the ring to rise, and then keeps it suspended.

If m^2 denote the area of a section of the ring made by a vertical plane perpendicular to the surface of the plate, then m^2, or $m^2 \times 1$, will be the volume of a portion of the fluid equal in weight to $\text{H}' - \frac{1}{2}\text{H}$.

Elevation of a fluid between two parallel plates.

If two parallel plates, AB and CD (fig. 5), very near one another, have their lower ends immersed in a fluid, it is observed that the fluid will rise between them above the natural level. Conceive a superficial canal extending between the plates in a direction at right angles to their surfaces, having its depth equal to the greatest range of the corpuscular force, and its horizontal width equal to unit; then all the fluid below the canal will be in equilibrium with respect to the attractive forces that act upon it, and therefore the suspended weight must be supported by the action of the two plates upon the canal. Of the forces which act upon the canal, we may neglect the attraction of the fluid below it, which causes the particles in the inside to press perpendicularly on the bottom. At each end it is attracted by the plates with a force equal to K′, or $\frac{1}{2}\text{K} + (\text{K}' - \frac{1}{2}\text{K})$, and, at the vertical sides between the

plates, by the fluid on the outside with a force equal $\frac{1}{2}$K. Wherefore, when the canal is reduced to equilibrium by equalizing the pressure upon its sides, there will remain at each end an excess of force equal to K′—$\frac{1}{2}$K, which compresses the fluid upon the plates; and the compressive force is necessarily accompanied with a lateral pressure equal to H′—$\frac{1}{2}$H, which tends upwards and supports the weight of the fluid suspended below the canal.

Hence the weight elevated between the plates, in the horizontal length λ, is equal to $2(H'-\frac{1}{2}H) \times \lambda$; and, since $m^2 \times 1$ is the volume corresponding to the weight $(H'-\frac{1}{2}H) \times 1$, the volume corresponding to the weight $2(H'-\frac{1}{2}H) \times \lambda$ will be equal to $2m^2 \times \lambda$. Let D denote the distance of the plates, and Q the least height of the curve surface between them above the natural level; then, if we conceive a horizontal plane touching the curve surface at its lowest point, the whole fluids between the plates in the length λ will be composed of a small curved portion in the shape of a meniscus, and a parallelopiped equal in volume to $\lambda \times D \times Q$. Now, when the plates are very near one another, and the elevation is considerable in comparison of their distance, the meniscus will be so small that the parallelopiped alone may be reckoned equal to the whole volume of the fluid. Hence, if we equate the two expressions of the same bulk, we shall get

$$D \times Q = 2m^2;$$

which proves that the elevations of a fluid between plates of the same matter are reciprocally proportional to the distances of the plates; and this agrees with observation.

Elevation of a capillary tube. When a capillary tube, or one with a bore less than one tenth of an inch, is partly plunged in a fluid, the fluid will rise within the tube above the level on the outside. Let AB and CD (fig. 5) represent the sides of such a tube, MHN the curve surface of the elevated column, having below it an imaginary surface at a depth equal to the range of the corpuscular force, and conceive two planes intersecting one another in the axis of the tube at any angle, then all the fluid below the superficial stratum will be in equilibrium with regard to the attractions to which it is subjected; and the triangular portion of that stratum, bounded by the inside of the tube, and the two planes intersecting in the axis, would likewise be in equilibrium, if the pressures upon all its vertical sides were equal. But the side in contact with the tube is attracted with a force equal to K′, or $\frac{1}{2}K + (K' - \frac{1}{2}K)$; and each of the other two sides is attracted with a force equal to $\frac{1}{2}$K; therefore, when the equilibrium of the attracting forces is provided for, there will remain an unbalanced pressure, proportional to K′—$\frac{1}{2}$K, upon the inside of the tube; and this direct compressive force is accompanied with a lateral tendency, proportional to H′—$\frac{1}{2}$H, which is directed upward, and sustains the elevated fluid between the two intersecting planes.

If π denote the circumference of a circle that has its radius equal to unit, and r the radius of the capillary tube, then $(H' - \frac{1}{2}H) \times r\,\pi$ will be the weight of the elevated column of fluid within the tube, and $m^2 \times r\,\pi$ will be its bulk. Conceive a plane which touches the curve surface of the column at its lowest point, and let q be the height of that point above the level on the outside of the tube, then the elevated column will consist of a cylinder equal to $\frac{1}{2}\,r^2\,\pi\,q$, and a small meniscus above the cylinder; so that, in very small tubes, the cylinder may be taken for the whole bulk of the column; wherefore, by equating the two expressions of the same bulk, we get

$$\tfrac{1}{2}\,r \times q = m^2;$$

which proves that, in small tubes of the same matter, the elevations are reciprocally proportional to the radii or diameters of the tubes.

And because m^2 is the same in all cases, when plates and tubes of the same matter act on the same fluid, if we equate the values of it taken from the last expression, and from the expression formerly obtained for two plates, we shall get

$$H \times Q = r \times q;$$

and this shows that a fluid will rise between two plates, to the same height it would do in a tube of the same matter having its radius equal to the distance of the plates.

Theory of Dr Jurin. The deductions that have now been drawn from the principle of a corpuscular attraction evanescent at all sensible distances, are equivalent to the account of capillary action founded on the hypothesis of Dr Jurin. Whatever may be thought of the physical principle advanced by this philosopher, it must be allowed that his theory agrees well with observation; and it cannot be denied that he has, with great sagacity, inferred from his experiments the true place in which the capillary force resides. But it is impossible to accede to his opinion, that, when a capillary tube of glass is immersed in water, the water within the tube is attracted upward by a narrow ring of glass immediately above the surface of the liquid. If the glass attract the water, the attraction must be perpendicular to the surface of the glass; the force acting on the fluid cannot be vertical, it must be horizontal; and if we would reason strictly, the proper inference must be, that an attraction between the glass and the water is alone insufficient to account for capillary action. In order to explain the phenomena, it is necessary to attend to the remark of Professor Leslie, founded on the properties essential to fluidity, namely, that a fluid cannot be attracted horizontally by a solid body, without having a vertical force communicated to it. It is certainly not a little surprising, that an observation made in 1802, so well calculated to remove all the difficulties of the theory, should have passed entirely unnoticed, although, since that period, the subject has engaged the attention of the first philosophers of the age.

In what goes before, it has been shown that, in many cases, the height to which a fluid will rise may be found with considerable exactness, by comparing the bulk as determined by the magnitude of the capillary force with the same bulk deduced from the figure which the displaced fluid is constrained to assume; but a rigorous investigation of all the circumstances attending the capillary phenomena requires further, that we know the nature of the curve assumed by that part of the fluid's surface which is free to obey the impulse of all the forces that act upon it; and it is to this branch of the subject that we are now to proceed.

8. Resuming the first and simplest case of a single plate immersed in a fluid, which rises upon its surface in a concave ring, let a vertical plane PL (fig. 4), parallel to the plate, and at a distance from its surface greater than the range of the corpuscular force, be drawn to intersect the curve; then the part of the ring cut off, being without the sphere of the plate's attraction, must be supported by the force with which it is attracted by the fluid between the plate and the plane. Now, all the fluid below the superficial stratum is in equilibrium with regard to the corpuscular forces to which it is subjected; and hence it is the attraction of the fluid between the plate and the plane upon the superficial stratum which supports the part of the ring below the plane, in the same manner that the attraction of the plate upon the same stratum supports the whole ring. All the fluid in the vessel being supposed in equilibrium, we may conceive that the portion of it between the plate and the plane is converted into a solid without any other change of its properties; then if we consider that part of the superficial canal which lies between the vertical plane and the level surface of the fluid,

the upper end of it will be pressed against the imaginary solid by the attraction of an obtuse-angled wedge of the fluid, while the pressure upon all the other vertical sides is only equal to the attraction of a right-angled wedge; and the difference of these forces remaining unbalanced, generates the force which tends upward, and supports the weight of the part of the ring situated below the point of its action.

It is now necessary to determine the attractive force of a portion of a fluid, in the shape of a wedge, contained in any proposed angle. Suppose that a fluid mass bounded by the plane AB (fig. 6) is divided by the plane PQ; and let it be required to find the force with which the attraction of the particles contained in each of the wedges APQ and BPQ will cause a small drop placed at P to press upon the plane AB. Draw PN and PG to bisect the angles APQ, BPQ; let the line PH, perpendicular to the plane AB, represent the force K, or the pressure of the drop caused by the attraction of all the fluid below the plane, sect. 3; and draw HN and HG perpendicular to PN and PG. It is manifest that the attraction of all the particles in the wedge APQ is a force in the direction PN; and, in like manner, the attraction of the particles in the wedge BPQ is a force in the direction PG. Wherefore, since PH, the united effect of both attractions, is resolved into the forces PN and PG, it follows that PN will represent the attraction of the obtuse-angled wedge upon the drop, and PG that of the acute-angled wedge. Draw NO and GL perpendicular to PH; then PO is the part of the force PN acting at right angles to the plane AB, and PL is the like part of the force PG. Draw NG, and let φ denote the angle HPQ, or the difference of each of the angles APQ and BPQ from a right angle. Then NG and PH are equal and bisect one another. Also, the angle PHG = BPG, each being the complement of HPG. Wherefore GCP = 2PHG = 2BPG = BPQ; and, taking the complements of the equal angles, CGL = CNO = HPQ = φ. Now GC = $\frac{1}{2}$PH = $\frac{1}{2}$K; hence CL=CO = $\frac{1}{2}$K sin. φ; therefore PO = $\frac{1}{2}$K + $\frac{1}{2}$K sin. φ, and PL = $\frac{1}{2}$K — $\frac{1}{2}$K sin. φ. Thus the pressure of the drop upon the plane AB, caused by the attraction of the obtuse-angled wedge, is equal to $\frac{1}{2}$K + $\frac{1}{2}$K sin. φ; and that caused by the attraction of the acute-angled wedge is equal to $\frac{1}{2}$K — $\frac{1}{2}$K sin. φ.

Curve formed upon the surface of a solid.

Returning now to the canal below the vertical plane PL (fig. 4), and the level surface of the fluid, let θ denote the inclination of the curve at L to the horizon; the canal would be in equilibrium with respect to the corpuscular forces that act upon it, if the attractions upon all its vertical sides were equal. But, according to what has just been investigated, the upper end is attracted by the fluid beyond the vertical plane PL, with a force equal to $\frac{1}{2}$K + $\frac{1}{2}$K sin. θ; and the attraction upon each of the remaining sides is only equal to $\frac{1}{2}$K; wherefore there is an excess of attraction equal to $\frac{1}{2}$K sin. θ, which causes the drop of liquid at the upper end of the canal to press upon the fluid above it, and which will be attended with a lateral force, equal to $\frac{1}{2}$H sin. θ, acting upward and sustaining the part of the ring cut off by the vertical plane.

Let $\beta^2 \times 1$ denote the volume of a portion of the fluid equal in weight to $\frac{1}{2}$H. Then $\frac{1}{2}$H sin. θ will be the weight, and β^2 sin. θ the bulk, of the partial ring cut off by the plane PL in the horizontal extent equal to unit. Let y denote the vertical ordinate of a point in the curve, formed by the intersection of the ring, with a vertical plane perpendicular to the plate; and let x be the corresponding horizontal ordinate, or the distance of y from the plate. Then the area of the curve below the point L is equal to $\int ydx$, the fluent vanishing with y; and the volume of partial ring in the horizontal extent equal to unit, is equal to $1 \times \int ydx$. Hence if we put $z = \sin.\theta$, and equate the two expressions of the same bulk, we shall get these equations, which are sufficient to determine the nature of the curve, viz.

$$\beta^2 z = -\int ydx$$

$$-\frac{dy}{dx} = \frac{z}{\sqrt{1-z^2}}:$$

the negative signs must be used, because z and y both decrease when x increases.

From the first of these equations we get

$$-ydx = \beta^2 dz;$$

and, if this be multiplied into the second equation, there will result

$$ydy = \frac{\beta^2 zdz}{\sqrt{1-z^2}};$$

that is, since $z = \sin.\theta$, $ydy = \beta^2 d\theta \sin.\theta$; whence $y^2 = 2\beta^2 (1 - \cos.\theta) = 4\beta^2 \sin.^2 \frac{1}{2}\theta$; and

$$y = 2\beta \sin.\tfrac{1}{2}\theta.$$

Again, $dz = d\theta \cos.\theta = d\theta(1 - 2\sin.^2\frac{1}{2}\theta)$; therefore

$$-dx = \frac{\beta^2 dz}{y} = \beta \cdot \left\{\frac{\frac{1}{2}d\theta}{\sin \frac{1}{2}\theta} - 2\cdot\tfrac{1}{2}d\theta \sin.\tfrac{1}{2}\theta\right\};$$ and hence

$$-x + \beta \log.\tan.\tfrac{1}{4}t - 4\beta \sin.^2\tfrac{1}{4}t = \beta \log.\tan.\tfrac{1}{4}\theta - 4\beta \sin.^2\tfrac{1}{4}\theta,$$

t being the value of θ when $x=0$. Therefore

$$x = \beta \times \log.\frac{\tan.\frac{1}{4}t}{\tan.\frac{1}{4}\theta} - 4\beta\left\{\sin.^2\tfrac{1}{4}t - \sin.^2\tfrac{1}{4}\theta\right\}$$

The value of the ordinate shows that x increases without limit as y decreases; whence it follows that the curve has an asymptote in the level surface of the fluid.

Curve between two parallel plates.

In like manner, we may investigate the curve formed by the intersection of the fluid between two parallel plates and a vertical plane perpendicular to the plates. Let y denote the height above the natural level of a point in the curve, and x the distance of y from the middle of the plates, or from the point where y is least. Suppose two vertical planes, PO and QR (fig. 5), parallel to the plates and at equal distances from them; then, as before, the fluid on the outside of the planes PO and QR will attract the ends of the superficial canal between them with a force equal to $\frac{1}{2}$K + $\frac{1}{2}$K sin. θ; and, as the part $\frac{1}{2}$K is alone sufficient for the equilibrium of the canal, it follows that the other part $\frac{1}{2}$K sin. θ will compress the fluid in contact with the two planes, producing thereby a lateral pressure that tends upward and sustains the weight of the suspended fluid. Hence the weight of the fluid suspended between the planes PO and QR, in every unit of the horizontal length, is equal to $2 \times \frac{1}{2}$H sin. θ; and its bulk is equal to $2\beta^2$ sin. θ. But the same bulk is also equal to $2 \times \int ydx$, the fluent vanishing with x. Wherefore, by putting $z = \sin.\theta$, and equating the two expressions of the same bulk, we get the equations

$$\int ydx = \beta^2 z,$$

$$\frac{dy}{dz} = \frac{z}{\sqrt{1-z^2}},$$

which determine the nature of the curve.

By combining the two equations, we get $ydy = \frac{\beta^2 zdz}{\sqrt{1-z^2}}$: now let $u = \sin.\frac{1}{2}\theta$; then $z = \sin.\theta = 2u\sqrt{1-u^2}$, and $\frac{dz}{\sqrt{1-z^2}} = \frac{2du}{\sqrt{1-u^2}}$: hence $ydy = 4\beta^2 udu$, and

Capillary Action.

$$y = 2\beta\sqrt{q^2 + u^2},$$

$2\beta q$ being the height of the lowest point of the curve above the level.

Again, $dx = \frac{\beta^2 dz}{y} = \beta \cdot \frac{du(1-2u^2)}{\sqrt{(1-u^2)(q^2+u^2)}}$; therefore,

$$x = \beta \cdot \int \frac{du(1-2u^2)}{\sqrt{(1-u^2)(q^2+u^2)}};$$

and x will be obtained by the rectification of the conic sections.

Curve surface in a capillary tube.

In the case of a capillary tube, conceive an imaginary tube, of which the sides are PO and QR (fig. 5), within the real one, and let θ denote the inclination of the curve surface to the horizon at the points P and Q. The elevated column within the imaginary tube is supported by the attraction of the fluid between the two tubes, in the same manner that the whole capillary column is supported by the attraction of the solid matter of the real tube. The fluid in contact with the imaginary tube on the outside having the shape of a wedge contained in the obtuse angle $90° + \theta$, will attract the fluid in the inside in a horizontal direction with a force equal to $\frac{1}{2}K + \frac{1}{2}K \sin. \theta$; and of this force, the part $\frac{1}{2}K \sin. \theta$ will compress the fluid ring on which it acts, producing, by this means, a lateral tendency upward, proportional to $\frac{1}{2}H \sin. \theta$, which supports the weight of the suspended column. If r denote the radius of the imaginary tube, then $\frac{1}{2}H \sin. \theta \times r\pi$ will be equal to the weight, and $\beta^2 \sin. \theta \times r\pi$ to the bulk of the elevated column within that tube; and if y be the vertical ordinate of a point in the curve surface, or the height above the natural level, and r the horizontal distance of y from the axis of the tube, the bulk of the same column will be equal to $\pi\int yrdr$, the fluent vanishing with r. Wherefore, by equating the equivalent expressions, we shall get the following equations, which determine the nature of the curve surface, viz.

$$\beta^2 rz = \int yrdr,$$

$$\frac{dy}{dr} = \frac{z}{\sqrt{1-z^2}}.$$

If these equations be combined so as to exterminate y, a differential equation between r and z will be obtained, viz.

$$\frac{d.\left(\frac{d.rz}{rdr}\right)}{dr} = \frac{1}{\beta^2} \times \frac{z}{\sqrt{1-z^2}}.$$

Curve when a fluid is depressed below the level.

9. Having explained the most remarkable instances of elevation by capillary action, we must now turn our attention to the cases where a fluid is depressed below the level by the same cause. It has been shown that an elevation will always take place when K′ and H′ are greater than $\frac{1}{2}K$ and $\frac{1}{2}H$, and that the fluid will remain level when the same quantities are equal. It follows, therefore, that the fluid will sink below the level when the former quantities are less than the latter; or otherwise there could not be an equilibrium. The shortest and most perspicuous manner of explaining the cases when a fluid is depressed is to compare them with the similar cases of an elevation. Suppose that AB and *ab* (fig. 7 and 8) are two plates of different kinds of matter immersed in the same fluid, which they attract with intensities equally above and below the mean quantity $\frac{1}{2}K$, we shall prove that the same curve which is formed above the level on the surface of the one, will be in equilibrium by the action of the other when placed upon its surface in a reversed position below the level.

Conceive the two curves to be intersected at intervals equal to the range of the corpuscular force by an indefinite number of planes parallel to the plates; and let the curves at L and l have the same inclination, θ, to the horizon. In the curve above the level (fig. 7), it has been shown that the force which tends upward, and supports the part of the ring below L, is equal to $\frac{1}{2}H \sin. \theta \cdot$ and, in like manner, the force which supports the part of the ring below the point O, indefinitely near L, is equal to $\frac{1}{2}H.(\sin. \theta + d \sin. \theta)$. Therefore the difference of these forces, or $\frac{1}{2}H \cdot d \sin. \theta$, which may be considered as a force urging the curvilineal element OL upward, is equal to the weight of the fluid elevated between the planes passing through O and L. In effect, if we put y and x to denote the vertical and horizontal ordinates of the point L, and equate the two expressions of the bulk of the small portion of fluid above mentioned, we shall get

$$\beta^2 d \sin. \theta = \beta^2 dz = ydx,$$

which is no other than the differential of the equation formerly obtained (sect. 7). We may therefore conceive that every element of the curve is urged upward with a force equal to the weight of the elevated fluid below it, the attraction of the plate supplying the force necessary to sustain the accumulated weight of all the suspended fluid.

In the curve below the level (fig. 8), the fluid on the same side of the plane *tl* with the plate *ab*, attracts the particles on the other side of that plane; and as the attracting fluid forms an acute-angled wedge contained in the angle $klt = 90° - \theta$, the horizontal attraction will be equal to $\frac{1}{2}K - \frac{1}{2}K \sin. \theta$; and the lateral force thence arising, and acting vertically, to $\frac{1}{2}H - \frac{1}{2}H \sin. \theta$. The point l of the curve is therefore urged upward by the attraction of the fluid between it and the plate *ab*, with a force equal to $\frac{1}{2}H - \frac{1}{2}H \sin. \theta$; and in like manner, the point o indefinitely near l, tends upwards with the force $\frac{1}{2}H - \frac{1}{2}H \cdot (\sin. \theta + d \sin. \theta)$. The difference of these forces, which may be considered as a force applied to the curvilineal element *ol*, is equal to $-\frac{1}{2}Hd \sin. \theta$; and it is the same in quantity as in the other curve, but has an opposite direction. The difference in the directions of the two forces acting upon the elements of the two curves arises from this, that, in the curve above the level, the force acting upward continually increases from the level surface to the plate, whereas, in the curve below the level, it continually decreases. Again, because OL and *ol* are placed at equal distances above and below the general level of the fluid, the weight drawing the element OL downward will be just equal to the vertical pressure caused by the superincumbent fluid, and urging the element *ol* upward. It thus appears that the forces which act upon the like elements of the two curves are the same in quantity, but that they have their directions reversed; which proves that, because the one curve is in equilibrium, the other will be so too; at least this will be the case if the attraction of the plate *ab* be sufficient to maintain the lowest point of the convex curve in its place.

The parts of the curves between the level surface of the fluid and the planes TL and *tl* are kept in their places by the horizontal attraction of the fluid on the other side of the same planes. These attractions are respectively equal to $\frac{1}{2}K + \frac{1}{2}K \sin. \theta$, and $\frac{1}{2}K - \frac{1}{2}K \sin. \theta$; and the one as much exceeds the mean quantity $\frac{1}{2}K$ as the other falls short of it. Now, in place of the attractions of the fluid particles contained in the wedges KLT and *klt*, we may substitute the attractions of two solid plates that act upon the fluid with equal forces; and these plates will come under the condition we have supposed with respect to the attractions of the plates AB and *ab*. It follows, therefore, that, because the attraction of the plate AB main-

tains the concave curve in its place, the attraction of the plate ab will be sufficient to maintain the convex curve in its place.

It is evident that the same reasoning which has been applied to two solid plates will apply equally in all other cases, and we may lay down this general proposition, viz. If two solid bodies, perfectly equal and similar, but composed of different kinds of matter, be immersed in a fluid which they attract with intensities equally different from the mean quantity $\frac{1}{2}$K, the fluid will be raised above the level by the action of the one, and depressed below the level by the action of the other, and the convex curve below the level will differ from the concave curve above the level in no respect, except that it will have a reversed position.

Limit to the elevation and depression of a fluid.

As no bounds can be set to the attractive force which a solid body exerts upon the particles of a fluid, it may be asked, will the weight displaced by capillary action increase in proportion to the attraction of the solid? or, are there any conditions that confine the effect within a certain limit, however great may be the attraction of the solid? In answer to this, it must be observed, that the action of the solid matter is confined to a thin film of the fluid in contact with it; and that it is this film alone which acts on the particles beyond it, and keeps them suspended by means of the force of cohesion. Hence the weight maintained above the level can never exceed what this last force is able to support. The elevation of the fluid will there be regulated by the attractive force of the solid matter, only so long as that force is less than the mutual attraction of the fluid particles; and the fluid will always rise to the same height when the attraction of the solid matter is either equal to or greater than the fluid's cohesion. In all these cases, the solid is wetted by the fluid, and we may conceive that it becomes covered with a coating of sufficient thickness to shield the particles on the outside from the attraction of the solid matter, a new body being thus formed, which attracts the fluid with a force equal to its own cohesive power.

From the relation that has been shown to take place between the cases of equal elevation and depression, it follows that the greatest depression will take place when a solid has no attraction for the particles of a fluid. If we go beyond this limit, and suppose that the solid matter repels the fluid, the capillary effect will not be heightened; for the repulsive force will be confined to the particles within the range of its action; beyond this insensible distance the repelling power will produce no effect, and the fluid will be left to assume the same figure it would do if no such power existed.

10. In the several cases that have been considered, the weight of the fluid suspended below that point of the curve surface which is inclined to the horizon in the angle θ, has been found to be equal to $\frac{1}{2}$H sin. θ; wherefore, if ε denote the angle of contact, or the angle in which the surface of the fluid intersects the solid, then $90°-\varepsilon$ will be the limit of θ, or what θ becomes at the surface of the solid; and consequently the weight of the whole fluid suspended by capillary action will be equal to $\frac{1}{2}$H cos. ε; but, as has likewise been proved (sect. 7), the same weight is also equal to $H'-\frac{1}{2}H$; and hence, by equating the equivalent quantities, we get

$$H' = H \cos.^2 \tfrac{1}{2}\varepsilon.$$

This expression is possible only when H′ is not greater than H; but we must not infer that the theory leads to any contradiction in the case where a solid body attracts the particles of a fluid with an intensity greater than their own mutual action upon one another. The equation is a consequence of the equality that takes place between the vertical force $H'-\frac{1}{2}H$ derived from the attraction of the solid, and the weight of the displaced fluid deduced from the figure which the attraction of its own particles causes it to assume. It is, therefore, only the effective part of the force $H'-\frac{1}{2}H$, or that which is really employed in displacing the fluid, that can enter into the equation; and when a part of the same force has no effect in elevating or depressing the fluid, that part must be neglected. Now it has been proved that, however great the force $H'-\frac{1}{2}H$ may be, the capillary effect can never exceed that produced by the force $H'-\frac{1}{2}H$ (sect. 9); and hence it appears, from the principle on which the investigation proceeds, that, in the equation, H′ must be limited not to exceed H, which must be taken for its value in all cases when the solid matter acts upon the fluid particles with an intensity either equal to or greater than their own mutual attraction.

From this equation it follows that the angle of contact is always the same when different solids of the same attractive powers are immersed in the same fluid, a property that was first noticed by Dr Young.

The weight of the displaced fluid being equal to $\frac{1}{2}$H cos. ε, is in every case proportional to the cosine of the angle of contact.

Investigation of Laplace's formula for the attraction of a fluid mass bounded by a curve surface.

11. In order still farther to illustrate and confirm the principles of the theory we have been explaining, we shall conclude this article with applying them to demonstrate the formula found by Laplace for the attraction of a fluid mass bounded by a curve surface.

Conceive a fluid mass bounded by a curve surface concave outward, and let the plane MAN (fig. 9) be a tangent, and the straight line AO a normal, to the curve surface at any point A; through AO draw any two planes perpendicular to one another, which cut the surface of the fluid in the curve lines BA and CA, and let DC and DB be two other sections of the fluid's surface made by planes parallel to the first planes, and indefinitely near them. Put ds and ds' for the small curve lines AB and AC; and $d\theta$ and $d\theta'$ for the measures of the small angles which the tangents drawn to the curve lines from the points B and C make with the tangent plane MAN. The four planes intersecting the fluid contain within them a rectangular prism, standing upon the base ABDC, and extending into the interior of the fluid mass at right angles to the curve surface; it is required to find the force which urges the prism outward above the tangent plane.

Conceive a surface intersecting the prism at a depth below its base equal to the range of the corpuscular force; then all the fluid of the prism below this imaginary surface being an equilibrium with regard to the attractions to which it is subjected, we have only to examine the forces that act upon the superficial stratum. It is attracted by the particles below the imaginary surface, and by the fluid on the outside of the force bounding planes. The attraction of the particles below the imaginary surface is at every point perpendicular to that surface; and therefore the stratum would be in equilibrium, if the attractions upon its four sides were equal. The fluid on the outside of each of the two planes AB and AC is a rectangular wedge; and consequently the attractions upon the particles within the stratum causing them to press perpendicularly upon these planes, are each proportional to $\frac{1}{2}$K. On the outside of the plane DC, the fluid is a wedge contained in the obtuse angle $90°+d\theta'$; and on the outside of the plane BD, it is a wedge contained in the obtuse angle $90°+d\theta$; the attraction is therefore proportional to $\frac{1}{2}K+\frac{1}{2}K d\theta'$ in the first case, and to $\frac{1}{2}K+\frac{1}{2}K d\theta$ in the other case. Hence, after the attractions upon the sides of the stratum are equalized, there is an excess of force perpendicular to each of the planes CD and DB,

amounting respectively to $\frac{1}{2}\mathrm{K}d\theta'$ and $\frac{1}{2}\mathrm{K}d\theta$. These direct forces produce the corresponding lateral pressures $\frac{1}{2}\mathrm{H}d\theta'$ and $\frac{1}{2}\mathrm{H}d\theta$; of which the first is the force in the length equal to unit, urging the fluid in contact with the plane CD to ascend above the tangent plane, and the second is the like force acting upon the fluid in contact with the plane BD. Therefore the actual forces which, in the lengths DC and DB, impel the superficial stratum, and consequently the prism attached to it by cohesion, above the tangent plane, are respectively equal to $\frac{1}{2}\mathrm{H}d\theta' ds$ and $\frac{1}{2}\mathrm{H}d\theta ds'$. It must be observed that these forces, like the curvatures from which they arise, are independent of one another; and that any alteration in the intensity of one will in no degree affect the action of the other. We may therefore conceive them to be applied to the prism one after the other; in which case the centre of gravity of the prism will have the same motion communicated to it as it would have if it were acted upon by the sum of both, or by the single force,

$$\tfrac{1}{2}\mathrm{H}d\theta' ds+\tfrac{1}{2}\mathrm{H}d\theta ds';$$

and this must therefore be considered as the effective force which pushes the prism above the tangent plane.

Let R and R′ be the radii of the circles that have the same curvature with the sections BA and CA, at the point A; then the small arcs AB and AC will subtend angles at the centres of the circles respectively, equal to $d\theta$ and $d\theta'$; consequently $ds=\mathrm{R}d\theta$, and $ds'=\mathrm{R}'d\theta'$; $d\theta=\frac{ds}{\mathrm{R}}$, and $d\theta'=\frac{ds'}{\mathrm{R}'}$; and if these values be substituted in the expression of the force, it will become

$$\tfrac{1}{2}\mathrm{H}\cdot\left\{\frac{1}{\mathrm{R}}+\frac{1}{\mathrm{R}'}\right\}\cdot dsds'.$$

Since ds and ds' are entirely arbitrary, we may suppose that $dsds'$, the base of the prism, is constant or equal to unit; then the measure of the attractive force arising from the curvature of the surface, and lifting the prism above the tangent plane, will be equal to

$$\tfrac{1}{2}\mathrm{H}\cdot\left\{\frac{1}{\mathrm{R}}+\frac{1}{\mathrm{R}'}\right\}.$$

This expression would not be a proper measure of the attractive force, unless $\frac{1}{\mathrm{R}}+\frac{1}{\mathrm{R}'}$ have the same value at the same point of the curve surface, for any two planes perpendicular to one another and to the curve surface; but this is a well-known property belonging to all curve surfaces.

If the surface of the fluid be convex outward, the preceding expression will become negative, and the force will change its direction and draw the prism inward, below the tangent plane.

The force arising from the curvature of the surface is independent of the direct attraction of the fluid mass upon the prism. This last force is proportional to K; it is the same whatever be the figure of the fluid, and it is always directed inward. (Sect. 3.) The whole force which draws inward a column upon a given base is, therefore, proportional to

$$\mathrm{K}-\tfrac{1}{2}\mathrm{H}\cdot\left\{\frac{1}{\mathrm{R}}+\frac{1}{\mathrm{R}'}\right\}.$$

This is the formula of Laplace; and the manner in which we have attained it proves clearly that the symbol which makes its appearance in the analytical operations of the illustrious geometer, is, in reality, the measure of the lateral pressure necessarily attending the direct attraction of the particles of a fluid.

In a fluid mass, which is subjected to no forces but the attractions of its own particles, and which is in equilibrium, if we conceive a slender canal passing through the interior and forming a communication between any two points of the surface, the canal will be in equilibrium taken separately (fig. 1). Of the forces in action at the ends, those which arise from the direct attraction of the whole mass, being equal and opposite, counteract one another in all positions of the canal; but the other forces, which depend on the curvature, and which in reality are nothing more than the lateral tendencies outward, produced by the direct attraction of the particles surrounding the two orifices, cannot be equal to one another in all positions of the canal, unless the function

$$\frac{1}{\mathrm{R}}+\frac{1}{\mathrm{R}'}$$

have the same value at all points of the curve surface, which is the case in no solid figure except a sphere. Such a body of fluid, therefore, cannot be in equilibrium, unless its form be perfectly spherical.

The formula of Laplace must be considered as a great step made in this branch of natural philosophy, not only because it ascertains the connection between the pressure and the curvature, in which it agrees with the hypothesis of Segner and Dr Young; but also because it brings into view the forces K and H, and draws the attention to the relation they have to one another, and to the primitive attraction of the particles. The labours of philosophers have discovered the facts of capillary action, which have been verified by innumerable experiments; but if the truth is to be told, it may be affirmed, that, reckoning back from the present time to the speculations of the Florentine academicians, the formula of Laplace, and the remark of Professor Leslie relating to the lateral force, are the only approaches that have been made to a sound physical account of the phenomena.

Method of computing the Depression of the Mercury in the Tubes of Barometers.

It is a problem of no small difficulty to determine the vertical ordinates of the curve surface in a capillary tube from the differential equations that have been investigated. The research possesses considerable interest, as it applies to the correction of the observed heights of the mercury in a barometer, by enabling us to compute the depression arising from capillary action. It is more particularly with a view to this application that the problem is here very briefly considered.

Resuming the equations of the curve surface in a tube, found in sect. 8, we get

$$y=\beta^2\left\{\frac{dz}{dr}+\frac{z}{r}\right\}$$

$$\frac{d\cdot\left(\frac{d\cdot zr}{rdr}\right)}{dr}=\frac{1}{\beta^2}\cdot\frac{z}{\sqrt{1-z^2}};$$

and if we put $x=\frac{r}{\beta}$, these equations will become

$$\frac{y}{\beta}=\frac{dz}{dx}+\frac{z}{x}$$

$$\frac{d\cdot\left(\frac{d\cdot zx}{xdx}\right)}{dx}=\frac{z}{\sqrt{1-z^2}}\quad\ldots\ldots(1).$$

In these equations, when $x=0$, we have $\frac{dz}{dx}=\frac{z}{x}$: and

hence, if q denote the elevation or depression, or the least value of y, then $\frac{q}{\beta} = 2\frac{z}{x}$, when $x = 0$.

When z is small, the equation (1) will coincide very nearly with the more simple equation

$$\frac{d\cdot\left(\frac{d\cdot wx}{xdx}\right)}{dx} = w \quad \ldots\ldots (2).$$

And if, in this last equation, we put $w=\lambda x$, $x^2=4t$, we shall get

$$\frac{dd\cdot\lambda t}{dt^2} = \lambda:$$

hence,

$$\lambda = 1 + \tfrac{1}{2}t + \frac{1}{1^2 2^2 3}t^2 + \frac{1}{1^2 2^2 3^2 4}t^3 + \&c.$$

Again, if we put $\lambda = c^{\frac{1}{2}\int vdt}$, c being the base of the hyperbolic logarithms, we shall get by substitution,

$$\tfrac{1}{2}\frac{dv}{dt}t + \frac{v^2}{4}t + v = 1;$$

and hence,

$$v = 1 - \frac{1}{6}t + \frac{1}{24}t^2 - \frac{1}{90}t^3 + \frac{13}{4320}t^4 - \&c.$$

Thus we have these two expressions of w, viz.

$$w = x\cdot\lambda = 2\sqrt{t}\cdot\lambda$$
$$w = x\cdot c^{\frac{1}{2}\int vdt} = 2\sqrt{t}\cdot c^{\frac{1}{2}\int vdt}$$

each of which, being multiplied by a constant quantity, will exhibit the general value, on the supposition that w vanishes with x: but the constant quantity is not necessary for the purpose we have in view.

Now, let $z = \frac{w\cdot s}{2}$: then, on account of the equations (1) and (2), we shall readily get

$$\frac{dds}{dx^2} + \frac{ds}{xdx} + 2\frac{dw}{wdx}\cdot\frac{ds}{dx} = \frac{s}{\sqrt{1-\frac{w^2s^2}{4}}} - s \ldots (A)$$

which may be thus written:

$$\frac{d\cdot\left(\frac{ds}{xdx}x^2\right)}{xdx} + 2\frac{dw}{wxdx}\cdot\frac{ds}{xdx}x^2 = \frac{s}{\sqrt{1-\frac{w^2s^2}{4}}} - s;$$

but $xdx = 2dt$, $\frac{ds}{xdx}x^2 = 2\frac{ds}{dt}t$, and $2\frac{dw}{wxdx} = \frac{1}{2}\cdot\frac{1}{t} + \frac{1}{2}v$; therefore, we have

$$\frac{d\cdot\left(\frac{ds}{dt}t\right)}{dt} + \frac{ds}{dt} + v\frac{ds}{dt}t = \frac{s}{\sqrt{1-\frac{w^2s^2}{4}}} - s;$$

and if we multiply both sides by $c^{\int vdt}$, and expand the radical on the right hand side, we shall get

$$\frac{d\cdot\left\{\frac{ds}{dt}t^2 c^{\int vdt}\right\}}{t\,dt} = \frac{t}{2}\cdot s^3\cdot c^{2\int vdt} + \frac{3t^2}{8}\cdot s^5\cdot c^{3\int vdt} + \frac{5t^3}{16}\cdot s^7\cdot c^{4\int vdt} + \&c.$$

In order to integrate this expression, assume

$$\frac{ds}{dt}t^2 = k^3\cdot M + k^5\cdot M' c^{\int vdt} + k^7\cdot M''\cdot c^{2\int vdt}, \&c.$$

$$s = k + k^3\cdot N + k^5\cdot N' c^{\int vdt} + k^7\cdot N''\cdot c^{\int 2vdt} + \&c.$$

then by substituting these values, and equating the terms containing the like powers of k, we shall get

$$\left.\begin{aligned}\frac{dM}{dt} + vM &= \frac{t^2}{2}\cdot c^{\int vdt}\\ \frac{dN}{dt} &= \frac{M}{t^2}\end{aligned}\right\}$$

$$\left.\begin{aligned}\frac{dM'}{dt} + 2vM' &= \frac{3}{8}t^3 c^{\int vdt} + \frac{3t^2}{2}N\\ \frac{dN}{dt} + vN' &= \frac{M'}{t^2}\end{aligned}\right\}$$

&c.

Now, if we expand $c^{\int vdt} = \lambda^2$ in a series, we shall get, by means of the first two equations, first a value of M, and then one of N, each in a series; and by a like procedure with the other equations, it will be found that

$$N = t\cdot Q = t\cdot\left\{\frac{t}{12} + \frac{t^2}{36} + \frac{11\cdot t^3}{1440} + \frac{t^4}{1200} + \frac{19\cdot t^5}{120960} + \&c.\right.$$

$$N' = t^2\cdot Q' = t^2\cdot\left\{\frac{t}{32} + \frac{t^2}{128} + \frac{17\cdot t^3}{5760} + \frac{t^4}{7560} + \&c.\right.$$

$$N'' = t^3\cdot Q'' = t^3\cdot\left\{\frac{t}{64} + \frac{3\cdot t^2}{640} + \frac{163\cdot t^3}{161280} + \frac{823\cdot t^4}{2257920} + \&c.\right.$$

$$N''' = t^4\cdot Q''' = t^4\cdot\left\{\frac{7\cdot t}{768} + \frac{t^2}{256} + \frac{t^3}{286720} + \&c.\right.$$

These formulæ will enable us to compute the value of Q, Q′, &c. with sufficient exactness when t is not extremely large. By substituting in the assumed value of $s = \frac{2z}{w} = \frac{2z}{x\cdot\lambda}$, and observing that $\lambda^2\ c^{\int vdt}$, we shall get

$$\frac{2z}{x\cdot\lambda} = k + k^3\cdot t\lambda^2\cdot\frac{Q}{\lambda^2} + k^5 t^2\lambda^4\cdot\frac{Q'}{\lambda^2} + \&c.$$

and hence if we put $f = \frac{kx\lambda}{2z}$, we shall have

$$1 = f + f^3\cdot\frac{Qz^2}{\lambda^2} + f^5\cdot\frac{Q'z^4}{\lambda^2} + f^7\cdot\frac{Q''z^6}{\lambda^2} + f^9\cdot\frac{Q'''z^8}{\lambda^2} + \&c.\,.\ (3)$$

In this method of proceeding the co-efficients in the series for f are in every case very small, and decrease so fast, that a few of the first terms determine the value of f with sufficient exactness. In reality, as t increases, each of the co-efficients increases from 0 to a certain limit; whence it follows that f will decrease from 1 to a certain limit, which is greater than $\frac{24}{25}$.

In order to prove what has been advanced, and to determine the limit of f, assume $w = \frac{u}{\sqrt{x}}$, and substitute in the equation (2); then,

$$\frac{ddu}{dx^2} = \left(1 + \frac{3}{4}\cdot\frac{1}{x^2}\right)\cdot u:$$

Again, put $u = c^{\int\varrho dx}$; then,

$$\frac{d\varrho}{dx} + \varrho^2 = 1 + \frac{3}{4}\cdot\frac{1}{x^2};$$

and hence,

$$\varrho = 1 + \frac{3}{8}\cdot\frac{1}{x^2} + \frac{3}{8}\cdot\frac{1}{x^3} + \frac{63}{128}\cdot\frac{1}{x^4} + \&c.$$

In consequence of the different assumptions, we have

$$w = x\cdot\lambda = \frac{c^{\int\varrho dx}}{\sqrt{x}}.$$

The expression $\frac{c^{\int\varrho dx}}{\sqrt{x}}$ will represent every value of w that vanishes with x; for it vanishes with x, and we conceive that $\int\varrho dx$ contains an arbitrary constant not necessary to be determined here.

If now we substitute this value of w in the equation (A), and observe that $2\frac{dw}{wdx} = -\frac{1}{x} + 2\varrho$, we shall get

$$\frac{dds}{dx^2} + 2\varrho\frac{ds}{dx} = \frac{s}{\sqrt{1-\frac{s^2}{4x}\cdot c^{2\int\varrho dx}}} - s.$$

and, by multiplying both sides by $c^{2\int\varrho dx}$, and expanding the radical, we have

$$\frac{d\cdot\left\{\frac{ds}{dx}c^{2\int\varrho dx}\right\}}{dx} = \frac{1}{4}\cdot\frac{s^3}{2}\cdot\frac{c^{2\int\varrho dx}}{x} + \frac{1}{16}\cdot\frac{3s^5}{8}\cdot\frac{c^{4\int\varrho dx}}{x^2} + \&c.$$

In order to integrate this expression, we may assume

$$\frac{ds}{dx} = \frac{k^3}{4}\cdot M\, c^{2\int\varrho dx} + \frac{k^5}{16} M'\, c^{4\int\varrho dx} + \&c.$$

$$s = k + \frac{k^3}{4}\cdot N\, c^{2\int\varrho dx} + \frac{k^5}{16}\cdot N'\, c^{4\int\varrho dx} + \&c.$$

then, by substituting and proceeding as before, we shall get

$$\left.\begin{aligned} &\frac{dM}{dx} + 4\varrho\cdot M = \frac{1}{2}\cdot\frac{1}{x} \\ &\frac{dN}{dx} + 2\varrho\cdot N = M \end{aligned}\right\}$$

$$\left.\begin{aligned} &\frac{dM'}{dx} + 6\varrho M' = \frac{3}{8}\cdot\frac{1}{x^2} + \frac{3}{2}\cdot\frac{N}{x} \\ &\frac{dN'}{dx} + 4\varrho N' = M' \end{aligned}\right\}$$

&c.

By means of the first two equations we get

$$N = \frac{1}{16}\cdot\frac{1}{x} + \frac{3}{64}\cdot\frac{1}{x^2} + \frac{1}{128}\cdot\frac{1}{x^3} - \frac{9}{128}\cdot\frac{1}{x^4} - \&c.$$

This series will coincide with its first term in the extreme case when x is very great; and by applying the like method of investigation to the other quantities sought, it will be found that

$N = \frac{1}{16}\cdot\frac{1}{x}$; $N' = \frac{5}{256}\cdot\frac{1}{x^2}$; $N'' = \frac{119}{12288}\cdot\frac{1}{x^3}$;

$N''' = \frac{393}{65536}\cdot\frac{1}{x^4}$. Now, let these quantities be substituted in the assumed value of s, and, because

$$w = x\cdot\lambda = \frac{c^{\int\varrho dx}}{\sqrt{x}}$$, we shall get

$$= \frac{2z}{x\cdot\lambda} = k + \frac{1}{16}\cdot\frac{k^3x^2\lambda^2}{4} + \frac{5}{256}\cdot\frac{k^5x^4\lambda^4}{16} + \&c.$$

and hence, by putting $f = \frac{kx\lambda}{2z}$, $1 = f + f^3\cdot\frac{z^2}{16} + f^5\cdot\frac{5z^4}{256} + f^7\cdot\frac{119\cdot z^6}{12288} + f^9\cdot\frac{393\cdot z^8}{65536} + \&c.$

from which we derive

$$f = 1 - \frac{z^2}{16} - \frac{z^4}{128} - \frac{35\cdot z^6}{12288} - \frac{137\cdot z^8}{98304} - \&c.$$

This is the limit to which f tends as x increases, and with which it coincides when x is infinitely great.

It remains now to apply the formulæ that have been investigated. If, in the equation $\beta^2 zr = \int yrdr$ (sect. 8), we substitute $q + y'$ for y, we shall get

$$\beta^2 z = \frac{qr}{2} + \frac{\int y'rdr}{r},$$

and the smaller the diameter of the tube, the more nearly will this equation approach to $\beta^2 z = \frac{1}{2}qr$. Therefore, l being the diameter of the tube, the value of $4\beta^2 z$ will be equal to ql, that is, to the product of the elevation or depression by the diameter of the tube, when the bore is very small. When mercury is contained in tubes of glass, the value of $4\beta^2 z$, assigned by the English philosophers, is ·015; and Laplace, from the experiments of Gay Lussac, makes it equal to ·01469. There is also some uncertainty in the value of z, or the cosine of the angle of contact, which seems to be between the limits 0·75 and 0·729. We may assume $4\beta^2 z = \cdot 015$, and $z = \cdot 735$, whence $\beta = \frac{1}{14}$; these numbers being recommended by their simplicity, and lying between the limits of the errors of observation.

Now, $t = \frac{x^2}{4} = \frac{r^2}{4\beta^2} = \left(\frac{l}{4\beta}\right)^2 = \left(\frac{7\,l}{2}\right)^2$: the series denoted by λ, and the co-efficients of the series for f, will therefore be known in numbers, and hence f may be found. Again, when $x = 0$, we have $s = \frac{2z}{x\cdot\lambda} = \frac{2z}{x} = k = \frac{q}{\beta}$; and because $x = \frac{r}{\beta} = \frac{l}{2\beta}$, we get $f = \frac{kx\lambda}{2z} = \frac{ql\lambda}{4\beta^2 z}$; and hence

$$q = \frac{4\beta^2 z}{l\cdot\lambda}\times f = \frac{\cdot 015}{l\cdot\lambda}\times f \ldots (4).$$

If we compute the value of the limit to which f approaches when l is very great, we shall find $f = 0\cdot 9635$: and hence, in the case of tubes with very large diameters, we have

$$q = \frac{\cdot 015}{l\cdot\lambda}\times \cdot 9635 = \frac{\cdot 01445}{l\cdot\lambda} \ldots (5).$$

It remains to ascertain in what cases this last formula may be safely used.

If we make l successively equal to ·3 and ·4, we shall find

$l = \cdot 3$; $t = 1\cdot 1025$; $f = \cdot 9696$; $q = \cdot 02916$;
$l = \cdot 4$; $t = 1\cdot 96$; $f = \cdot 9649$; $q = \cdot 01534$.

Now, this last value of f approaches very nearly to the ultimate value; and if q be computed by the formula (5), we shall find

$$q = \cdot 01532.$$

We may therefore use the formula (5) in all cases when the diameter of the tube is greater than four tenths of an inch. In other cases, we must compute the depression by the formula (4), having first found f by means of the following expression, in which all the quantities too small to affect the exactness of the result are left out, viz.

$$1 = f + f^3 \times \frac{z^2}{\lambda^2} \cdot \left\{ \frac{t}{12} + \frac{t^2}{36} + \frac{11 \cdot t^3}{1440} + \frac{t^4}{1200} \right.$$
$$+ f^5 \times \frac{z^4}{\lambda^2} \cdot \left\{ \frac{t}{32} + \frac{t^2}{128} + \frac{17 \cdot t^3}{5760} \right.$$
$$+ f^7 \times \frac{z^6}{\lambda^2} \cdot \left\{ \frac{t}{64} + \frac{3 \cdot t^2}{640} + \frac{163 \cdot t^3}{161280} \right.$$
$$+ f^9 \times \frac{z^8}{\lambda^2} \cdot \left\{ \frac{7 \cdot t}{768} + \frac{t^2}{256} \right.$$

To compute f from this formula, assume $f = 1 - \alpha$: Then, α being always less than $\frac{1}{25}$, its square and higher powers may be neglected.

By the procedure just described, the following table has been constructed, in which all the numbers may be reckoned exact, with the uncertainty of one unit in the last place of figures.

Table of the Depression of Mercury in Glass Tubes.

Diam. of Tube.	Depression.	Diam. of Tube.	Depression.	Diam. of Tube.	Depression.
0·05 in.	0·29494 in.	·30 in.	·02916 in.	·60 in.	·00443 in.
·10	·14028	·35	·02110	·70	·00228
·15	·08628	·40	·01534	·80	·00119
·20	·05811	·45	·01117		
·25	·04075	50	·00835		

(J. I.)

The whole of the formulæ in this article are founded on the supposition that the distance to which molecular attraction extends, is inconceivably smaller than that to which the surface of a fluid is disturbed by the immersed plate.

The admissibility of this supposition has been denied by the writer of a paper given in the *Edin. Phil. Journal*, of date Feb. 1830; he contends that, on this supposition of Laplace, a particle placed at the point P of figure 6 is attracted by the adjoining fluid in a direction normal to the surface at P; but that, being beyond the range of attraction of the plate, the only other tendency is that of gravitation, so that the resultant must be in a direction *not* normal to the surface, and that, therefore, the fluid cannot be in a state of rest.

This difficult subject is treated of in a different manner under the head HYDRODYNAMICS, which see. See also MOLECULAR ATTRACTION.

CAPILUPI, CAMILLO, a native of Mantua, who lived in the sixteenth century, and wrote a book entitled *Lo Stratagema di Carolo IX.*, which is an account of the massacre on St Bartholomew's day. It is, however, blended with some fictions.

CAPILUPI, *Lelio*, younger brother of the preceding, was born at Mantua in 1498, and distinguished himself by some centos of Virgil which display considerable ingenuity. His several Latin poems are inserted in the *Deliciæ Poetarum Italorum*. He died in 1560. His brother Julio was also distinguished as a man of letters.

CAPISCOLUS, or CABISCOLUS, in ecclesiastical writers, denotes an official in certain cathedrals, answering to what in other churches is called *chanter* or *precentor*.

CAPITAL (from the Latin *caput*, the head), is used in various ways to express the relation of a head, chief, or principal: thus, CAPITAL *City*, the principal city of a kingdom, state, or province; CAPITAL *Stock*, in commerce, the sum of money which individuals contribute to make up the common stock of a partnership; CAPITAL *Crime*, such a one as subjects the criminal to capital punishment.

CAPITANATA, a province of the kingdom of Naples, in the southern part of Italy. It is bounded on the north and the east by the Adriatic sea, on the S.E. by the provinces Bari and Basilicata, on the south by the Principato-Ulteriore, on the west by Molise, and on the N.W. by Abruzzo. Area, 2920 square miles. On the N.E. the mountainous range of Gargano covers an extent of more than 800 square miles. On the S.W. side of the province the Apennines occupy a part of the space. Though the more mountainous parts are sterile, yet between them there are rich valleys. The chief products are wheat, maize, pulse, fruits, tobacco, liquorice, hemp, flax, oil, and wine. The breeding of cattle, especially of sheep, is very extensively pursued. The manufactures are few, the principal being those of linen, coarse hats, leather, and soap; and it has some little coasting-trade with the other Italian countries. Pop. (1851) 318,415. The province is divided into three districts, namely, Foggio, St Severo, and Manfredonia. The capital is Foggio.

CAPITANIA, an appellation given to the twelve governments established by the Portuguese in the Brazils.

CAPITATION, a tax or imposition upon each head or person; a poll-tax.

CAPITE, in *Law* (from *caput*, that is, *rex*, whence *tenere in capite* is to hold of the *king*, the *head* or lord-paramount of all the lands in the kingdom), an ancient tenure of land, held immediately of the king, as of the crown, either by knight's service or by soccage.

CAPITE *Censi*, in *Antiquity*, the lowest rank of Roman citizens, so denominated because they were rather counted by their heads than by their estates. The *capite censi* formed part of the sixth class of citizens, being below the *proletarii*, who constituted the other moiety of that class. They were not enrolled in the army, as being judged unable to support the expense of war; for originally the Roman soldiers maintained themselves. It does not appear that before the time of Caius Marius any of the Roman generals enlisted the *capite censi* in their armies.

CAPITO, or KOEPSTEIN, *Wolfgang Fabricius*, an eminent Reformed divine, born 1478, died 1541. On the termination of his studies at Basle, he removed to Strasburg, where he officiated as pastor till his death. He took a prominent part in the earlier ecclesiastical transactions of the sixteenth century, was present at the second conference of Zurich, and the conference of Marburg, and along with Bucer was appointed to present to the Emperor the confession of Augsburg. From his endeavours to conciliate the Lutheran and Zuinglian parties in regard to the sacraments, he seems to have incurred the suspicions of his own friends; while from his intimacy with several divines of the Socinian school, he drew down on himself the charge of a leaning to Arianism. He first married the widow of Œcolampadius, whose life he prefixed to an edition of his Commentary on Ezekiel. His second wife was a lady of great accomplishments, who was associated with him in his studies His death was caused by the plague. He wrote *Institutionum Hebraicarum libri duo; Enarrationes in Habacuc et Hoseam Prophetas;* and *Explicatio doctissima in Hexhameron opus Dei.*

CAPITOL, CAPITOLIUM, the temple of Jupiter at Rome; or rather a general denomination under which not only that edifice, but also the citadel, was included. The former occupied the southern summit of the Mons Capitolinus (formerly named Saturnius, and also Tarpeius); while the northern and somewhat more elevated summit of the hill was crowned by the *Arx* or citadel. The Capitolium is said to have been so called because in laying its foundations the head of a man (*caput Toli*) was dug up in a fresh and perfect condition. The building was commenced by Tarquinius Priscus, and completed by Tarquinius Superbus; but it was not dedicated till the third year after the expulsion of the kings, B.C. 507, when this ceremony was performed by the consul M. Horatius. It was destroyed by fire in B.C. 83, but was rebuilt by Sulla, and dedicated by Q. Catulus in B.C. 69; and was again burnt A.D. 70, by the soldiers of Vitellius, and rebuilt by Vespasian. In the reign of Titus, A.D. 80, it was burned a third time; but Domitian restored it with greater magnificence than ever.

The temple contained, under one roof, three *cellæ*, which were consecrated respectively to Jupiter, Juno, and Minerva

The central cell was the temple of Jupiter, who is hence called *media qui sedet æde Deus.*

The form of the Capitol was a square, 200 feet on each side; the gates were of bronze; and it was approached from the forum by a flight of 100 steps. Both the inside and the outside of the building were adorned with extraordinary magnificence, the gilding alone having cost 12,000 talents, a sum equivalent to L.1,976,250 sterling. In the Capitol the Sibylline books were deposited; here the consuls and magistrates offered sacrifices when they first entered upon their offices; and hither the victorious general to whom the honour of a triumph was decreed was conducted in his triumphal car.

The ancient Capitol also contained other temples, as those of Terminus, Jupiter Feretrius, &c. The term Capitol was likewise applied to the principal temples of other cities.

The Capitoline Mount, as being the highest part of Rome, and everywhere strongly fortified, was sometimes called simply *arx;* and sometimes the term Capitolium was applied to the whole hill. Again, in contradistinction to the arx proper, the capitol itself is sometimes called *Arx Tarpeia*, or *Arx Capitolina.* The site of the ancient temple is now in part occupied by the Palazzo Caffarelli, and that of the Arx by the church of Ara Celi. The ancient name of Capitolium has been corrupted into Campidoglio.

The present buildings, forming three sides of a square, were erected by Michael Angelo; and one of them contains the magnificent collection of antiquities known as the Capitoline Museum.

CAPITOLINE Games, (*Ludi Capitolini*), annual games instituted on the suggestion of Camillus, B.C. 387, in honour of Jupiter Capitolinus, and to commemorate the escape of the capitol from capture by the Gauls. One of the amusements at these games consisted in a herald's offering the Sardiani for sale by auction, and leading about an old man with a golden bulla about his neck, and wearing a toga prætexta, for the purpose of exciting merriment. (Plutarch; Festus). This ceremony, according to some ancient writers, was designed to ridicule the conquered Veientes, who were called Sardiani from Sardis the capital of Lydia, whence they were supposed to have come; while the old man represented their king in appropriate costume, since the use of the bulla, like that of the prætexta, was derived from the Etruscans. It is, however, more probable that the name Sardiani referred to the Sardinians, who were subdued by the Romans, B.C. 238, and sold as slaves, whose bad qualities gave occasion to the proverb—*Sardi venales; alius alio nequior.*

These games, after having fallen into oblivion, were re-instituted by Domitian, and under the name of *Agones Capitolini* were celebrated every fifth year, when rewards and crowns were bestowed on poets, champions, orators, historians, and musicians. These games became so famous that, instead of computing time by lustra, they began to calculate it by the Capitoline games, as the Greeks did by Olympiads; but this custom does not appear to have been of long continuance.

CAPITOLINUS, Julius, a Roman historian who flourished towards the end of the third and beginning of the fourth century. He wrote the biographies of Antoninus Pius, Marcus Aurelius Antoninus, L. Verus, Pertinax, Clodius Albinus, Opilius Macrinus, the Maximini, the Gordians, Maximus, and Albinus. His works are classed with those of Spartianus, Gallicanus, Lampridius, Pollio, and Vopiscus, under the title "*Historiæ Augustæ scriptores sex.*"

CAPITULARIES are certain laws enacted under the auspices of kings of the Frankish race. They are called *Capitularia* by a word of no classical authority, but derived from *capitulum*, the diminutive of *caput;* and they are so described from the circumstance of their being enacted or digested *capitulatim*, by heads or chapters.[1] The term is very frequently used in a general sense, but in other instances capitularies are distinguished from laws.

The laws of the Franks were enacted "consensu populi, constitutione regis." Liberty was the chief inheritance of the ancient people of Germany; nor were they governed by laws which they had no share in enacting. It has been remarked by Dr Stuart, that "the short, but comprehensive and sentimental work of Tacitus, on the manners of Germany, is the key to the institutions, the Capitularies, and the codes of the barbarians."[2] In the opinion of the same able jurist, the foundation and principles of the Anglo-Saxon constitution are to be found in the institutions and manners of the ancient Germans; and he has accordingly endeavoured to trace the most essential principles of that constitution to the forests of Germany. But the national assemblies of those who were capable and worthy of bearing arms, appear to have been gradually superseded by a select council, composed of the two orders of the clergy and nobility; and if the great body of the people attended their deliberations, it seems to have been more in the capacity of spectators than of actual legislators. This was the form of the constitution in the time of Charlemagne, in whose name a great proportion of the Capitularies are promulgated, though some of them belong to a more recent, and others to a much more early period, the collection commencing with an enactment of King Childebert, dated in the year 554. The Capitularies are written in the Latin language, and this task was doubtless performed by the ecclesiastics. The Latin copies were deposited among the national archives, but the laws were divulged to the people in their mother tongue.[3]

Savigny, whose name ought to be familiar to all those who study the history or jurisprudence of the middle ages, has supplied us with the following statement:—"The imperial ordinances of the Franks, *Capitularia*, which, after the extension of their empire, were distinguished from the national laws, *Leges*, arose from the enlargement of the same principle. All royal enactments, particularly in later times, were called Capitularia, or Capitula. The king had a double character; the one, as chief of each individual tribe, and the other as head of the whole nation. Hence the Capitularies also are of two classes; those defining the law of a particular race; *e. g.* 'Capitula addita ad Legem Salicam,' and those of general application over the whole Frank territory. In the kingdom of the Franks, with which so many different nations were incorporated, the Capitularies are so frequently general under the Carlovingian dynasty, that when their character is not specially fixed they may be understood as belonging to that class. In Lombardic Italy on the contrary, where the Lombards and Romans were the only distinct people, most of the ordinances of Charles and his successors must be understood as constituting exclusively Lombardic law. For this reason, probably, they have been inserted in all the early collections of that law, and were consequently never obligatory on the Romans.—It is, however, of great importance to determine accurately the limits of the general Capitularies. The laws of the race of Charlemagne have been erroneously supposed to apply to all the subjects of their extensive empire. These princes reigned over three distinct kingdoms, the Frankish, Lombardic, and that which under the name of Rome and the Exarchate had recently constituted part of the Greek empire. No Capitulary, however general, could overstep the boundaries of that state in which it had originated. The only exceptions to this rule were some clerical laws; and their universal validity arose

from the unity of the church, and from the common old ecclesiastical authorities, on which they were founded. No example of a similarly general application is found in any of the temporal ordinances."[1]

The earliest editor of the Capitularies was Vitus Amerpachius, who published at Ingolstadt, in the year 1545, " Præcipuæ Constitutiones Caroli Magni de Rebus ecclesiasticis et civilibus." The history of the various editions we cannot here detail, but must refer the more inquisitive reader to the copious and elaborate preface of Baluze, who has himself surpassed all preceding and all subsequent editors. His great collection appeared under the following title: " Capitularia Regum Francorum; additæ sunt Marculfi monachi et aliorum Formulæ veteres,[2] et notæ doctissimorum virorum: Stephanus Baluzius Tutelensis in unum collegit, ad vetustissimos codices manuscriptos emendavit, magnam partem nunc primum edidit, notis illustravit." Paris, 1677, 2 tom. fol. This valuable work was long afterwards reprinted in Italy; Venetiis, 1771, 2 tom. fol. Another edition, for which Baluze had himself made preparations, remains to be mentioned:[3] " Nova editio, auctior ac emendatior ad fidem autographi Baluzii, qui de novo textum purgavit, notasque castigavit et adjecit: acessere Vita Baluzii, partim ab ipso scripta, Catalogus Operum hujus viri clarissimi, cum animadversionibus historicis, et Index variorum Operum ab illo illustratorum, quorum plurimorum novas meditabatur Editiones: curante Petro de Chiniac, Regi a Consiliis, Prosenescallo Generali Civili Userchæ, e Regia Humaniorum Litterarum Academia Montis-Albani." Paris, 1780, 2 tom. fol. This edition is splendidly printed, but is somewhat disfigured by a French translation of the preface, exhibited column for column. The Capitularies may likewise be found in two more recent publications; in Georgisch's *Corpus Juris Germanici antiqui*, Halæ Magd. 1738, 4to, and in Canciani's *Leges Barbarorum antiquæ*. Venetiis, 1781–91, 5 tom. fol. (D. I.)

CAPITULATION, the act of capitulating or surrendering to an enemy upon stipulated terms or conditions.

CAPITULATION, in German polity, a contract which the emperor entered into with the electors, in the name of the princes and states of the empire, before he was raised to the imperial dignity.

CAPITULUM, in ecclesiastical writers, denoted part of a chapter of the Bible read and explained. In this sense they said, *ire ad capitulum*, to go to a lecture. Afterwards the place or apartment where such theological exercises were performed was denominated *domus capituli*.

CAPMANY, ANTONIO DE MONTPALAN Y (1742–1813), an eminent Spanish historian and philosopher, a native of Barcelona. He spent the early part of his life in military service; but abandoning it in 1770, he removed to Madrid, where he was elected secretary of the Royal Academy of History. His principal works are, *Memorias historicas sobre la Marina, Commercio y Artes de la antiqua ciudad de Barcelona*, 4to, Madrid, 1779–1792; *Teatro historico-critico de la Elocuencia castellana*, 4to, Madrid, 1786; *Dictionario Frances-Español*, 4to, Madrid, 1805; and *Questiones criticas sobre varios puntos de historia, economica, politica y militar*, 8vo, 1807.

CAPNOMANCY (καπνος smoke, and μαντεια divination), a kind of divination by means of smoke, used by the ancients in their sacrifices. When the smoke was thin and light, and rose straight, it was a good omen; if the contrary, it was a bad one.

CAPO D'ISTRIA (the ancient *Ægida*), a fortified seaport-town of Illyria, in the government of Trieste, and circle of Istria. It stands on a small island in the gulf of Trieste. eight miles south of that city, and is connected with the mainland by a causeway half a mile in length. It is the seat of a bishopric, and has a cathedral and about thirty other churches, a citadel, gymnasium, prison, &c. It has manufactures of salt, leather, and soap; besides which it exports wine, oil, and fish. The harbour is large, but is little frequented except by fishing boats. Pop. 6000. E. Long. 13. 50., N. Lat. 45. 40.

CAPO D'ISTRIA, *John*, Count, was born at Corfu, where his father was a physician, in 1780. At first he devoted himself to the study of medicine in the academies of Padua and Venice, but joined the Russian diplomatic service when at the treaty of Tilsit the Ionian Islands were ceded to the French. He held the office of secretary for foreign affairs under the Emperor Alexander, and was president of the Greek republic after the battle of Navarino. Having been suspected of treachery to the republican cause, he was assassinated when entering a church at Napoli de Romania, October 9, 1831. See GREECE.

CAPON, a young cock that has been emasculated.

CAPONIERE, or CAPPONIERE, in *Fortification*, a covered lodgment sunk four or five feet into the ground, encompassed with a parapet about two feet high, serving to support several planks covered with earth. The caponiere is large enough to contain fifteen or twenty soldiers, and is usually placed in the glacis at the extremity of the counterscarp, and in dry moats, with embrasures through which the soldiers may fire.

CAPPADOCIA, an ancient kingdom of Asia Minor, comprehending originally all the country which lies between Mount Taurus and the Euxine Sea. It was divided by the Persians into two satrapies, which under the Macedonians were erected into two kingdoms, the one called *Cappadocia ad Taurum*, the other *Cappadocia ad Pontum*, and commonly *Pontus*. See PONTUS.

CAPPADOCIA AD TAURUM, or *Cappadocia Magna*, was bounded north by Galatia and Pontus; east by Armenia and Mount Taurus; west by Galatia and Lycaonia; and south by Mount Taurus. Its early history and condition are wrapped in obscurity. The only authentic accounts which have come down to us do not remount beyond the period of its subjection to Persia, and the native princes who held it in fief from the Persian king. The first of these was Pharnaces, who is said to have married Atossa, the sister of Cambyses, and to have been slain in a war with the Hyrcanians. The princes who succeeded him (Smerdis, Atamnas, Anaphas I. and II., Datames, Ariamnes I., Ariarathes I., and Olophernes) continued faithful to the Persian interest, and under Ariarathes II., who (disregarding the previous and somewhat fabulous line of kings), is generally called Ariarathes I., the Cappadocians continued to struggle for their independence, when the rest of the kingdom had been overrun and dismembered by Alexander the

See likewise Eichhorn's *Deutsche Staats und Rechtsgeschichte*, Th. i. S 346, and Conringius *De Origine Juris Germanici*, p. 88, edit Helmestad, 1720, 4to.

[2] In reference to this subject, the reader may consult a work entitled "Commentatio de Marculfinis aliisque similibus Formulis, Liber singularis; auctor Dr J. A. L. Seidensticker." Jenæ, 1818, 4to.

[3] The work described in the *Biographie Universelle* as a publication of various manuscripts, is merely a catalogue of Baluze's library. "Bibliotheca Baluziana, seu Catalogus Librorum Bibliothecæ v. cl. Stephani Baluzii Tutelensis." Paris, 1719, 2 tom. 8vo. This library contained 10,799 printed books, and many hundred manuscripts. Of one of his early publications, which we had no opportunity of inspecting, we have copied a French title from Niceron, but the work is written in Latin; " Disquisitio Seculi quo vixit Sanctus Sacerdos, Episcopus Lemovicensis." Tutelæ Lemovicum, 1655, 8vo.

Great. After the death of Alexander, Perdiccas, marching into Cappadocia with a powerful and well-disciplined army, succeeded in taking Ariarathes prisoner, and crucified him and all those of the royal blood who fell into his hands. His son Ariarathes II., however, having escaped the general slaughter, fled into Armenia, where he lay concealed till the civil dissensions which arose among the Macedonians after the death of Eumenes (to whom Perdiccas had surrendered the kingdom), gave him a favourable opportunity of recovering the throne. Having defeated Amyntas in a pitched battle, he compelled the Macedonians to abandon all the strongholds, and after a long and undisturbed reign, left his kingdom to his son Ariamnes II., under whose peaceful administration Cappadocia made great progress. Under Ariarathes III., who waged a successful war with Arsaces, founder of the Parthian monarchy, the territory of Cappadocia was considerably enlarged.

He was succeeded by Ariarathes IV., who joined Antiochus the Great against the Romans, and after his defeat was obliged to atone for taking up arms against the people of Rome by paying a fine of two hundred talents. He afterwards assisted the republic with men and money against Perseus king of Macedon, and was honoured by the senate with the title of *the friend and ally of the Roman people*. He left the kingdom to his son Mithridates, who took the name of Ariarathes V.

During the reign of this prince, surnamed *Philopater*, from the strength and constancy of his filial affection, the Cappadocians remained in close alliance with Rome. In the beginning of his reign, having been relieved from an invasion by Mithrobarzanes the king of Lesser Armenia, whom he himself had placed on the throne at the intervention of the republic, he presented the senate with a golden crown, and received in return a staff and chair of ivory. Not long before this, Demetrius Soter, king of Syria, had offered Ariarathes in marriage his sister, the widow of Perseus king of Macedon, an honour which he declined for fear of offending the Romans. Demetrius, greatly incensed at the slight, set up a rival to the throne of Cappadocia in the person of Olophernes a supposititious son of the deceased king, and succeeded in driving Ariarathes from his throne.

The usurper having sent a present to Rome in token of his allegiance, contrived to make his case appear so plausible to the senate that he was invested by them with a share of the kingdom; but in the following year he was expelled by Attalus, who had succeeded Eumenes on the throne of Pergamus.

Ariarathes, being thus restored, avenged the refusal of the Priennians to restore four hundred talents of gold which Olophernes had deposited with them, and would have stormed their capital if the Romans, to whom they appealed, had not commanded him to desist. Disappointed of his revenge in this respect, Ariarathes hastened into Assyria to avenge himself on Demetrius Soter, by whose instrumentality he had been driven from the throne. By joining his forces to those of Alexander Epiphanes, who had already taken the field against the Syrian king, the war was quickly ended. In the very first engagement Demetrius was slain, and his army entirely dispersed. Some years afterwards Ariarathes, having espoused the cause of the Romans in their contest with Aristonicus, a claimant of the throne of Pergamus, he was slain in the same battle in which Crassus proconsul of Asia was taken, and the Roman army cut to pieces. He left six sons by his wife Laodice, on whom the Romans bestowed Lycaonia and Cilicia. But Laodice, fearing lest her children when they came of age should take the government out of her hands, poisoned five of them; the youngest only having escaped her cruelty by being conveyed out of the kingdom. She was soon, however, put to death by her subjects, who rose in rebellion against her tyrannical government.

Laodice was succeeded by Ariarathes VI, who soon after his accession married Laodice, daughter of Mithridates the Great, wishing to gain the alliance of that powerful prince in his contest with Nicomedes king of Bithynia, who laid claim to part of his kingdom. Mithridates, however, instead of assisting, procured the death of Ariarathes by poison, and under pretence of maintaining the rights of the Cappadocians against Nicomedes, proclaimed himself regent till the children of Ariarathes should be competent to govern the kingdom. The Cappadocians at first acquiesced; but finding him unwilling to resign the regency in favour of the lawful king, they rose in arms, expelled the foreign garrisons, and placed Ariarathes VII., eldest son of the late king, on the throne.

The new prince found himself immediately engaged in a war with Nicomedes; but, being assisted by Mithridates, not only drove him out of Cappadocia, but stripped him of a great part of his hereditary dominions. On the conclusion of the peace, the refusal of Ariarathes to recal Gordius the murderer of his father, led to a war with Mithridates. When the two armies met on the frontiers of Cappadocia, Mithridates invited Ariarathes to a conference, and openly stabbed him with a dagger which he had concealed in his dress. The terror-stricken Cappadocians immediately dispersed, and submitted to the yoke of Mithridates; but, unable to endure the tyranny of his prefects, they quickly rose in rebellion, and recalling the exiled brother of the late king they placed him on the throne. He had scarcely ascended the throne when Mithridates invaded the kingdom at the head of a numerous army, defeated the army of the Cappadocians with great slaughter, and compelled Ariarathes VIII. to abandon the kingdom. The unhappy prince soon after died of grief, and Mithridates bestowed the kingdom on his own son, a youth only eight years old, giving him also the name of Ariarathes. But Nicomedes Philopater, king of Bithynia, dreading the increase of power in a rival already so formidable, claimed the throne for a youth who pretended to be the third son of Ariarathes, and whom he sent with Laodice to Rome, to advocate his cause. Having received the declaration of Laodice that the petitioner was one of three sons which she had borne to Ariarathes, and whom she had kept concealed lest he should share the fate of his brothers, the senate assured him that they would reinstate him in his kingdom. Mithridates, receiving notice of these transactions, despatched Gordius to Rome to advocate his cause, and to persuade the senate that the youth to whom he had resigned the kingdom of Cappadocia was the lawful son of the late king, and grandson to Ariarathes, who had lost his life in the service of the Romans against Aristonicus. On receiving this embassy, the senate inquired more narrowly into the matter, discovered the whole plot, and ordered Mithridates to resign Cappadocia. The Cappadocians enjoyed their freedom for a short time, but soon sent ambassadors to Rome, requesting the senate to appoint a king. Leave was given them to elect a king of their own nation; and as the family of Pharnaces was now extinct, they chose Ariobarzanes, who received the sanction of the senate, and continued steadily attached to the Roman interest.

Ariobarzanes had scarcely taken possession of his kingdom when he was driven out by Tigranes, king of Armenia, who resigned Cappadocia to the son of Mithridates, in terms of an alliance previously concluded between them. Ariobarzanes fled to Rome, and by the assistance of Sylla, who routed Gordius the general of Mithridates, he was quickly reinstated in his kingdom. On the retreat of Sylla, however, Ariobarzanes was again driven out by Ariarathes, the son of Mithridates, whom Tigranes had set up as king. By the intervention of Sylla, Ariobarzanes was again placed on the throne; and immediately after Sylla's death he was a third time forced to abandon his kingdom, when Pompey, after

defeating Mithridates near Mount Stella, restored the unfortunate monarch, and rewarded him for his services during the war with the provinces of Sophene, Gordyene, and a great part of Cilicia. Wearied with such a succession of disasters, soon after his restoration he resigned the crown to his son Ariobarzanes, and spent the rest of his life in retirement.

Ariobarzanes II. proved no less faithful to the Romans than his father had been. On the breaking out of the civil war between Cæsar and Pompey, he sided with the latter; but after the death of Pompey he was received into favour by Cæsar, who bestowed upon him a great part of Armenia. While the emperor was engaged in a war with the Egyptians, Pharnaces, king of Pontus, invaded Cappadocia and stripped Ariobarzanes of all his dominions; but Cæsar, after defeating Pharnaces, restored the king of Cappadocia, and honoured him with new titles of friendship. After the murder of Cæsar, Ariobarzanes, refusing to join Brutus and Cassius, was declared an enemy to the republic, and soon afterwards taken prisoner and put to death. He was succeeded by his brother Ariobarzanes III., who shared the same fate at the hands of Antony. With him the royal family became extinct.

Archelaus, the grandson of the general of the same name who commanded against Sylla in the Mithridatic war, owed his elevation to the throne of Cappadocia solely to the intrigues of his mother Glaphyra with Mark Antony, to whom he remained faithful in the contests with Augustus. On the defeat of Antony, he was pardoned by the emperor at the intercession of the Cappadocians, and received Armenia Minor and Cilicia Trachæa as a reward for having assisted the Romans in clearing the seas of pirates, who infested the coast of Asia. He contracted a strict friendship with Herod the Great, king of Judea; and married his daughter Glaphyra to Alexander, Herod's son. On the accession of Tiberius (who entertained a secret hostility to Archelaus on account of his previous neglect of his merits during the lifetime of Caius Cæsar), he was decoyed to Rome by the fair promises of Livia, the emperor's mother; but being accused before the senate, and loaded with reproaches at the court, he died of grief, after a reign of fifty years.

On the death of Archelaus, the kingdom of Cappadocia was reduced to a Roman province, and governed by men of the equestrian order. It shared the fortunes of the Eastern Empire till the rise of the Turkish power and the fall of Byzantium. Under the Turkish rule it is comprehended in the Ejalet, or government of *Ssiwas*.

In the time of the Romans, the inhabitants of Cappadocia were so infamous for vice and profligacy that among the neighbouring nations a worthless man was aptly termed a *Cappadocian*. The reception of Christianity, however, produced a wondrous change on the character of the population; and in the struggles of the early church we find them taking a prominent part. In ecclesiastical history, several of its cities have become among the most famous of antiquity. Nyssa and Nazianzum, the cities of the two Gregories; Cæsarea, the city of Basil; to say nothing of Tyana and Samosata.

We have now no system of the Cappadocian laws, and scarcely anything by which to form an estimate of Cappadocian jurisprudence. Their commerce was limited to a trade in horses, great numbers of which were reared in the tablelands, and taken to the fairs of Tyre to be sold; as we learn from Ezek. xxvii. 14. It is probable that they also acted as carriers of the mineral produce of the Cappadocian Pontus.

The religion of the ancient Cappadocians resembled that of the Persians, but was largely interspersed with Grecian myths. At Comana there was a rich and stately temple in which the bloody rites of Bellona were celebrated; and the temples of Apollo, Catanius, and Jupiter, were thronged with crowds of votaries. The chief priest of Jupiter was next in rank to that of Bellona, and, according to Strabo, had a yearly revenue of fifteen talents. Diana Persica was worshipped in a city called Castaballa, where women devoted to the worship of that goddess were reported to tread barefooted on burning coals without receiving any hurt. The temples of Diana at Diospolis, and of Anias at Zela, were likewise held in great veneration both by the Cappadocians and Armenians, who flocked to them from all parts. In the latter were taken all oaths in matters of importance; and the chief priest, who was attended by a royal retinue, possessed unlimited authority over all the inferior servants and officers of the temple. The Romans, who readily adopted all the superstitious rites of conquered nations, greatly increased the revenues of the temples, and thus made the priesthood the willing tools of their ambitious designs. It is said that human sacrifices were offered at Comana; and that this barbarous custom was brought by Orestes and his sister Iphigenia from Tauris Scythica, where men and women were immolated to Diana. But this custom, if ever it obtained in Cappadocia, was abolished in the times of the Romans.

CAPPOQUIN, a small town of Ireland, in the county of Waterford, on the Blackwater, 27 miles west of Waterford. Pop. (1851) 2145. It has a church, Roman Catholic chapel, and a dispensary.

CAPPERONIER, Claude (1671–1744), an eminent classical scholar, was the son of a tanner at Mont-Didier. He studied at Amiens and Paris, and took orders in the church of Rome, but devoted himself almost entirely to classical studies. He declined a professorship in the university of Basle, and was afterwards appointed to the Greek chair in the university of Paris. He published an edition of Quintilian, and left behind him at his death an edition of the Ancient Latin Rhetoricians. His nephew, Jean Capperonier, was also a famous linguist.

CAPRAJA, the ancient *Capraria*, a small island of the Sardinian States, lying in the Mediterranean, between the N.E. point of Corsica and the coast of Piombino. It is about 15 miles in circumference, and possesses a town of the same name, which has a good harbour. The principal product is wine. Pop. about 1000. E. Long. 9. 52. N. Lat. 43. 3.

CAPRI, the ancient *Capreæ*, a small island of Naples, on the south side of the entrance to the Bay of Naples, about 3 miles west of Cape Campanella. It is about 4 miles in length by 3 in breadth, and is almost surrounded by lofty cliffs, steep and inaccessible, except at the port of Capri, a small fortified town on its south side. The climate is mild and salubrious; but the greater part of the island is rocky, though where cultivated it is very fertile, producing grain, grapes, olives, and other fruits. Vast numbers of quails are annually caught here. Capri is celebrated in history as being the retreat of Tiberius, where he spent the last ten years of his life, and whence he issued the *verbosæ et grandes Epistolæ*, mentioned by Juvenal. He erected twelve villas in different parts of the island, the remains of several of which are still to be seen. Mosaic pavements, bas-reliefs, and other relics of antiquity, have been dug up here. Pop. about 6000.

CAPRIATA, Pietro Giovanni, an eminent Genoese lawyer and historian, who died about the year 1660. He wrote a history of the wars of Italy, entitled *Istoria sopra i Movimenti d'arme successi in Italia dell' Anno* 1613 *fino al* 1646. 8vo, 2 parts, Genoa, 1644–1648; and a third part was afterwards published by his son. The whole work was translated into English by Henry Earl of Monmouth, 1663, folio.

CAPRICORN (Latin *Capricornus*, from *caper* a goat, and *cornu* a horn), in *Astronomy*, one of the twelve signs of the zodiac; the winter solstice.

The ancients accounted Capricorn the tenth sign; but the stars being advanced a whole sign towards the east, Capricorn is now rather the eleventh sign; and it is at the

sun's entry into Sagittarius that the solstice happens, though the ancient manner of speaking is still retained.

This sign is represented on ancient monuments, medals, &c., as having the fore part of a goat, and the hind part of a fish, which is the form of an Ægipan; and sometimes simply under the form of a goat. In books it is characterized thus, ♑.

Capricorn, Tropic of, a lesser circle of the sphere, which is parallel to the equinoctial and at 23° 30′ distance from it southwards, passing through the beginning of Capricorn.

CAPSA, in *Ancient Geography*, a large and strong town of Numidia, the site of which is occupied by the modern Gafsa, 74 miles W.N.W. of Cabes.

CAPSICUM. See Cayenne Pepper.

CAPSTAN, or Capstern, a strong massive column of timber, formed like a truncated cone, and having its upper extremity pierced with a number of holes to receive the bars or levers. It is let perpendicularly down through the decks of a ship, and is fixed in such a manner that the men, by turning it horizontally with their bars, may perform any work which requires an extraordinary effort.

The following descriptions present a view of some important improvements on capstans by Captain Phillips of the royal navy. (See Plate CLVIII.)

Fig. 1 is an elevation of the upper capstan and works, and an elevated section of the lower capstan, of a frigate; A, the upper capstan, is fitted securely to the spindle by two iron crosses at the upper and lower ends of the barrel; B, the spindle, runs the full length of both capstans, is a fixture to the upper one, and revolves freely on turned bearings in the lower capstan; C C, a strong hexagonal plate, fitted to the spindle and upper part of the trundle-head. D D, the trundle-head, fits hexagonally over the barrel U, which is connected with the spindle by the plates C C and E E; the trundle-head is further secured by being bolted to the plate E E. By using a barrel instead of a plain trundle-head, a greater bearing is obtained upon the spindle, which must prevent the head from working, when the men bear much at the outer end of the bars. E E, the trundle-head lower plate, is fixed to the hexagonal part of the spindle, and to the trundle-head, as above described. F F are fixed bolts that connect the plates C and E together; G G, drop-bolts, that serve either to attach the trundle-head to, or detach it from, the lower body. The size of the bolts is larger in diameter than the largest mooring chain of a line-of-battle ship; and from there being three in use, there can be no risk of their breaking. H is an hexagonal part of the spindle, on which the plates C and E fit, as well as the barrel U. I I, the upper plate of the lower body, secures the body and whelps together. It has a circular hole in the centre, through which the spindle passes; the bearing is bushed with brass. K K, the lower body, is composed of a barrel, whelps, and pecul-head, like any other capstan, but revolving in turned bearings round the spindle. L L, drop-bolts, which attach the lower body to the frame that carries the works, or detach it from them, as may be required, by means of chains running over the upper cheek. M M, the lower plate of the body, revolves with a turned bearing round the spindle. N N, the frame that carries the centre of the intermediate pinions N N N, which frame revolves in turned bearings round the spindle. O, the centre pinion, is fixed to the spindle. P P, the large wheel, is a fixture to the beams. Q, a collar, is bolted to the spindle on which the lower body rests. R, a collar to support the frame U. S, the step, is a strong piece of wood passing from beam to beam; it is secured by bolts to the beams, and supported by stanchions from the deck; an iron cup with a brass bushing is let into it, to receive the lower end of the spindle.

Fig. 2 is a plan of the works used in fig. 1, which shows that the centre wheel is but one-half the size of the exterior wheel, although possessing a power of three to one. The parts of the works are lettered similar to those of fig. 1, being a plan corresponding with that elevation.

Fig. 3 is a plan of the works in fig. 4, the parts being lettered the same, and answering to the elevation described in fig. 4.

Fig. 4 shows the elevation of the upper capstan, with the works partly in section, partly in elevation, and an elevated section of the lower capstan of a frigate. A, the upper capstan, is firmly secured to the spindle by crosses and an iron bolt. B, the spindle, which runs the length of both capstans, is a fixture to the upper one and false head, but revolves freely in the lower capstan. C C, the false head, is attached to a hexagon on the spindle; it may be let on in halves, and when fixed to the spindle will prevent the lower capstan from rising. D D, the lower capstan, is made entire; head, whelps, body, and pecul-head, similar to any other capstan, but revolving in turned bearings round the spindle. E, the collar that carries the lower capstan. F, the partners, are made like those of plain capstans, with iron spindles, with a cup let in to receive the toe. G G, drop-bolts, which serve to connect or disconnect the false head to the lower capstan. H H, the standards, are secured at their base to the trundle-head, and on their upper end is fixed a circular ring, which supports the centres of the intermediate pinions N N N; which ring is attached by pillars to the upper flange N N, with the pinions working between the plates N N. O, the centre pinion, is let on the hexagonal part of the spindle, and is consequently a fixture to it. Q Q, the guides, are iron carriages, that are secured to the beams, and in which the bolts R R traverse. R R, the bolts which serve to fix the large wheel when the increased power is in use, by grooves in stubbs, fixed at opposite diameters of the rim of the large wheel. These bolts slide backwards and forwards in the guides Q Q. S S is a blocking of wood attached to the beams to support the carriages of the bolts R R. T T are the upper and lower deck beams, shown in section.

Fig. 5 is an elevation of the lower capstan of a frigate, with the spindle separated beneath the quarter-deck, and is constructed in every way similar to fig. 1, excepting that the trundle-head is connected to the body and whelps, and plays loosely round the spindle. A fixed head or plate, firmly secured to the spindle, attaches the lower capstan to the spindle by the upper deck bolts G G; it will therefore be only necessary to describe those parts that differ from fig. 1. C C, the false head, is secured to the spindle on an hexagonal bearing; D, the trundle-head, is a fixture to the lower body. The bolts G G and L L will be correspondent in strength to the spindle.

The mode of using these capstans will be more fully understood by referring to the letters in the plate and description.

When the upper bolts G G in fig. 1 are down, and the lower ones L L are suspended by the chains to the upper cheek, the capstan has no power beyond the leverage of the bars, as the works are totally disconnected with the capstans. To increase the power, elevate the bolts G G, and let the chains loose that suspend the bolts L L, when these bolts will fix themselves by their weight in the frame N N, and thus connect the lower body with the works. By the upper bolts G G being elevated, the lower body becomes detached from the head; and in this state, when the upper capstan is hove round, the lower capstan receives its motion by the bolts L L through the medium of the works. The lower head D, being a fixture to the spindle, has the power of setting the works in motion, as well as the upper capstan, and consequently the power may be acted upon on either deck. When all the bolts are up, the capstans are separated; the lower capstan will then remain stationary, and the upper capstan may be used to spring the ship, or for

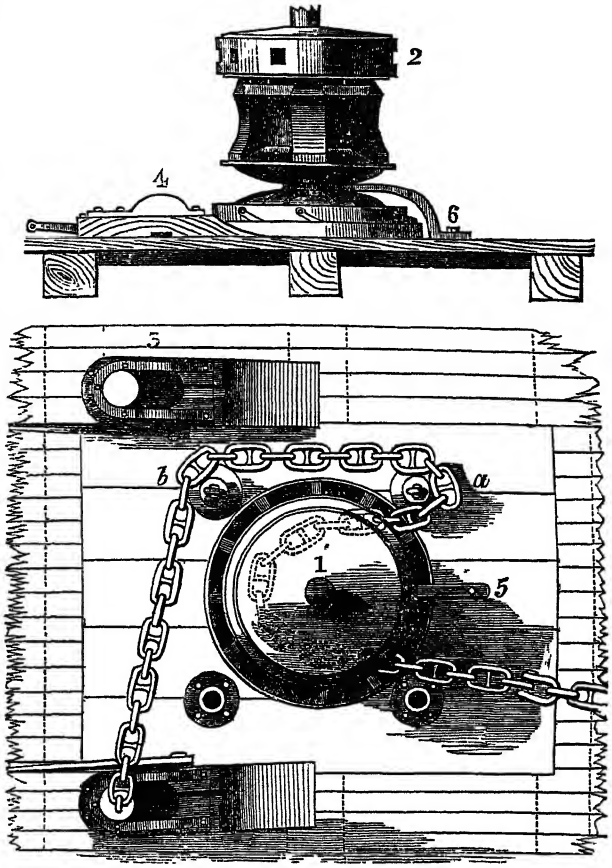
any other distinct purpose, whilst the messenger may remain during this period passed round the lower capstan body, ready to weigh the anchor.

In fig. 4 the works are between the quarter-deck beams. To increase the power, lock the large wheel P (that is, secure it by the bolts R R), and disconnect the false head C C from the lower capstan by elevating the bolts G G. Heave round on the quarter-deck capstan, and the power will be in action by the lower capstan being set in motion by the pillars H H through the medium of the works. To use it as a plain capstan, unlock the large wheel by withdrawing the bolts R R, and dropping the upper bolts G G, when both capstans and the works will traverse round together. To disconnect the capstans (that is, to use them for separate purposes), suspend the bolts G G and withdraw the bolts R R, when the works will go round with the lower capstan by means of the pillars H H, and the spindle with the upper one.

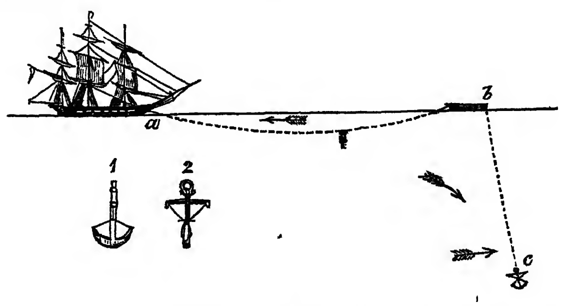
In fig. 5 the false head is a fixture to the spindle, and the lower capstan revolves round it. To increase the power, elevate the bolts G G, and drop the lower bolts L L. To use the capstan for separate purposes, lift all the bolts and keep them suspended; to make it a plain capstan, suspend the lower bolts L L, and keep the upper ones G G down.

The wheel work is so arranged that the power may be applied or relieved from it almost instantaneously; and the leading feature of the improvement is, that both capstans traverse the same way, either as a plain capstan, or when set in motion by the machinery; and the increase of power obtained is in the ratio of one revolution of the first mover more than the revolution gained by the difference of diameter between the first period and the large wheel. This is gained by making the large wheel stationary, and the centres of the intermediate pinions the means of communication with the capstan. Considerable improvements have of late years been made in Phillips' capstans, which in their original form are not now much used in her Majesty's service. A part of Phillips' plan, however, is retained, that namely of connecting the upper and lower capstan together, on the latter of which marked * on Plate CLVIII., there is a toothed wheel, which in revolving enters the link of the chain-messenger. This latter is relieved after going half round the capstan, which is likewise fitted for a rope-messenger in case the chain become defective. A French plan was recently devised (marked in the Plate*), in which, instead of the wheel, an iron flange is fitted to take the three cables (the one above and the other below the class, or rate, for ships), and by this means a messenger is not required. Messengers are generally of chain; but rope ones are also supplied to each ship in case the chain ones should become defective. The chain-messenger is made with a large link and a small one. This latter the spikes of the wheel enter as the wheel revolves. This messenger is passed half round the capstan, taken forward round the rollers in the bow, and the two parts of the messenger shackled together. Rope-messengers are passed three times round the capstan, and with an eye at each end lashed together. The rope-messengers in all ships are cut from five to eight fathoms longer than the distance between the capstan and the bow, in order that the men may hold on when the cable is hove in. Nippers made of rope from four to five fathoms long are used to attach the cables to the messenger. These are taken off when the cable is hove in, and come aft to the chain locker (or if the cable is hempen to the hatchway near the tier).

A patent has lately been taken out by Mr Thomas Brown of London, in which various improvements are introduced. The principal of these are illustrated in the sub joined woodcuts. The numbers 1 and 2 represent the pla and elevation of the capstan flange, for working various sizes of chain cable; 3 and 4 are the plan and elevation of the deck-pipe stopper, to be used for checking the cable when bringing the ship to, and for riding by when at anchor; 5 and 6 are the plan and elevation of the clearing guide.



The following woodcut represents Mr Aylen's mode of anchoring a ship during a calm, when out of soundings, to prevent her drifting when a strong current is running against her.



Supposing a ship of from 500 to 600 tons in a calm, with the current running three knots against her, and out of soundings; let go the kedge anchor, having previously secured two pieces of canvas to it as per figure, No. 1 and 2; veer out 40 to 50 fathoms of 3 to 4 inch hawser; then lower the quarter boat or cutter, and stop the above hawser to the ring in the bow and stern of the boat; then veer from the ship 70 to 80 fathoms on the hawser, between the boat and ship; put on a snatch block to traverse, with one or two pigs of ballast, to be used according to the strength of the current.

Supposing that the current at from 40 to 50 fathoms deep is running in a different direction from that of the surface—as has been frequently observed in clear water at sea—

it is plain that a great strain is taken off the anchor by using the boat, inasmuch as the whole strain would be on the hawser *b c*, the greater part of which is borne by hawser *a b*; that if the ship rode immediate at *b*, the whole of the strain being at *b c*, would naturally require a greater weight to hold her; in fact, a bower anchor with 60 fathoms of cable would not be sufficient, besides the difficulty of again recovering the anchor.

If the surface and deep current should happen to run in the same direction, the ship would not then separate from the boat; all would drift together. This plan for anchoring, there is every reason to suppose, will answer near the equator, or at any place at a distance from the main land, but it is not intended for a tide way. (J. A.)

CAPTAIN (French *capitaine*, Italian *capitano*, from the Latin *caput*), literally a head, or chief officer; but the term is used in particular to denote an officer holding a certain rank in the army or the navy. In the army, a captain is the officer who commands a troop of cavalry, or a company of infantry, or of artillery. His full pay in horse regiments is 14s. 7d. a-day; in the infantry 11s. 7d. Captains in the Life and Foot Guards rank with the Colonels of other regiments, and their full pay is 15s. a-day.

CAPTAIN-*General*, the commander-in-chief of an army, or of the militia.

CAPTAIN-*Lieutenant*, is an officer who, with the rank of captain, but the pay of lieutenant, commands a troop or company in the name and place of some other person. Thus the colonel of a regiment being usually captain of the first company, that company is commanded by his deputy under the title of *Captain-Lieutenant*.

CAPTAIN *of a Ship of War*, the officer who commands a ship of the line or a frigate. Officers who command smaller vessels are called commanders. In ships of the line a commander is also appointed with the captain; the former is therefore second captain. The charge of a captain in her majesty's navy is very comprehensive, inasmuch as he is not only answerable for any bad conduct in the military government, navigation, and equipment of the ship he commands, but also for any neglect of duty or mismanagement on the part of his inferior officers, whose several charges he is appointed to superintend and regulate. See NAVY.

CAPTAIN *of a Merchant Ship*, he who has the direction of the ship, crew, lading, &c. He is more ordinarily called the *master*.

CAPTAIN *Bashaw*, or *Capudan Pasha*, the Turkish high admiral. He possesses the third office of the empire, and is invested with the same power at sea as the vizier has on shore. Solyman II. instituted this office in favour of the famous Barbarossa, with absolute authority over the officers of the marine and arsenal.

CAPTION, in *Scots Law*, a writ issuing under her majesty's signet, in her majesty's name, obtained after decree at the instance of a creditor in a civil debt, commanding messengers at arms and other officers of the law to apprehend and imprison the person of the debtor until he pay the debt.

CAPTIVITY, a term distinctively applied to the expatriation of the Jewish people. See JEWS.

CAPTURE, a prize or prey, particularly that of a ship taken at sea. See PRIZE.

CAPUA, a large and important city of ancient Italy, capital of Campania, was situated in the midst of a very fertile and valuable territory two miles from the bank of the Vulturnus, and about half that distance from the mountain Tifata. Much diversity of opinion has prevailed as to the date of its foundation, and the people by whom it was originally inhabited. It is now generally agreed that Capua was one of the twelve cities which the Tuscans were said to have founded in the south of Italy at the beginning of the ninth century B.C. The city soon rose in importance, and its inhabitants became renowned throughout the whole peninsula for their wealth, and the luxurious magnificence of their lives. In course of time, as was natural, they degenerated so far, that from having been originally a brave and warlike people, they could no longer resist the encroachments of the Samnites, who in 424 B.C. made themselves masters of the city, and put the inhabitants to the sword. The material prosperity of the city remained undiminished under the rule of the Samnites, who in less than a century had become as effeminate and degenerate as the Capuans had been. When they in turn were attacked by the mountaineers, they were compelled to apply to Rome for assistance, which was immediately granted. At the close of the Latin war, in which the Capuans had assisted the allies, they were deprived of the *Campanus Ager* the most valuable district in Italy, but were admitted to take rank as citizens of Rome. They still continued, however, to select their own rulers. When the second Punic war broke out, the Capuans, elated with the prospect of retrieving their high position, opened their gates to Hannibal, who spent an entire winter with his army in the city. To the enervating contagion of Capuan effeminacy, historians have always attributed the want of success which subsequently attended the Carthaginian commander in his Italian campaigns. When the Romans at length made themselves masters of the city, in the seventh year of the war, they took a terrible revenge, and only forbore to raze the city to the ground in consideration of the great natural advantages of its site. For its fidelity in the social war, the Romans restored to Capua all its municipal privileges, and the city recovered all its commercial, though it never regained its political importance. Under Julius Cæsar, the Campanus Ager was distributed among 20,000 citizens of Rome, and Capua became a Roman colony. Under the emperors it continued to prosper commercially, and seems to have been as rich and populous at the downfal of the western empire as during the time of its political independence, and its wealth marked it out as a special object of attack to the Vandals, who took and nearly destroyed it under Genseric, A.D. 456. What was left undone by the Vandals was completed by the Saracens, who burnt the city to the ground in 840. The inhabitants who had fled for shelter to the neighbouring mountains returned on the departure of their eastern invaders, and established themselves at Casilinum, a stronghold distant a short way from their ancient home. Casilinum is the modern Capoua, one of the strongest forts in the kingdom of the Two Sicilies. The site of the ancient Capua is now occupied by the village of Casale, in the neighbourhood of which extensive ruins of the old capital of Campania may still be distinctly traced.

CAPUCHINS, monks of the order of St Francis, who cover their heads with a stuff cap or cowl, *capuce* or *capuchon;* whence their name. They are clothed in brown or gray, go barefooted, and never shave their faces. The Capuchins are a reformed body of the order of Minors, commonly called *Cordeliers*, and were instituted in the sixteenth century by Matthew de Baschi, a *frater de Observantia* of the monastery of Montefiascone. Matthew, who was an honest but simple man, imagined that he was commissioned by a special revelation from heaven to restore the institutes of St Francis to their original integrity; and with this view, after obtaining permission from Clement VII., in 1525 he retired with many followers to a desert. In 1528 they obtained the pope's bull; and in the following year the order was brought into complete form, Matthew was elected general, and the chapter framed constitutions. In 1543 the right of preaching was taken from the Capuchins by the pope, but in 1545 it was restored. In 1578 there were already seventeen general chapters in the order of Capuchins.

CAPUT, a Latin word signifying the head, chief, &c.

Caput *Baroniæ*, the head of the barony, in ancient customs, denotes the chief seat or castle of a nobleman, where he held his court. It was sometimes also called *caput honoris*, or the head of the honour. The *caput baroniæ* could not be settled in dowry, nor divided among the daughters in case there were no son to inherit, but descended entire to the eldest daughter, *cæteris filiabus aliunde satisfactis*.

Caput *Lupinum*. In ancient times an outlawed felon was said to have *caput lupinum*, *i.e.* a *wolf's head*, and might be slain by any one who should meet him.

Caput *Mortuum*, a fanciful Latin term used by the old chemists to denote the fixed residue of chemical operations, from which the volatile matters had been driven off.

CAR, a splendid kind of chariot used in triumphs, and at the entries of princes. The word is derived from the ancient Gaulish or Celtic *carr* mentioned by Cæsar in his *Commentaries* under the name of *carrus*. The car on medals, when drawn by horses, lions, or elephants, usually signifies either a triumph or an apotheosis; sometimes it indicates a procession of the images of the gods; and sometimes of those of some illustrious family at a funeral.

The word car is used to denote several kinds of modern carriages, usually of light construction, and drawn by one horse.

CARABINE, or Carbine, a short gun carrying a ball of twenty-four to the pound, borne by light horsemen, and hung by a belt suspended over the left shoulder. The barrel is two feet and a half long, and the bore is sometimes rifled.

CARABINEERS, or Carbiniers, regiments of light horse, carrying longer carabines than others, and sometimes employed on foot.

CARACALLA, Marcus Aurelius Antoninus, the Roman emperor, was born at Lyons a.d. 188. His original name was Bassianus, and the name Caracalla was derived from the favourite long tunic which he wore and introduced into the army. On the death of his father Severus, whom he made an open attempt to assassinate, he ascended the throne with Geta his brother. He soon procured the assassination of his colleague, and sacrificed twenty thousand persons of both sexes who were suspected of belonging to his brother's party. The rest of his reign was spent in wandering from place to place, making havoc wherever he went, in an endeavour to banish the recollection of his past guilt by engaging in new enormities. In Alexandria he repaid the pleasantries in which the inhabitants had indulged by a general massacre; and he laid waste Mesopotamia in revenge for a slight which he had received from Artabanus the Parthian king. On his progress to Carrhæ, he was assassinated at the instigation of Macrinus, his successor, a.d. 217. See Roman History.

Caracalla, in *Antiquity*, an outer garment provided with a capuchin or hood, and not unlike the Roman *lacerna*. The caracalla, as worn in Gaul, reached no lower than the knee; but after its introduction by the Emperor Aurelius Antoninus Bassianus (who thence obtained the surname of Caracalla), it was lengthened so as to reach the ankle, and its use became general among the Romans, both in the city and the camp. Such garments were commonly called Antonian, to distinguish them from the Gallic caracalla. (Aurel. Vict. *Epit.* 21; *De Cæs.* 21; Spartian. *Sev.* 21.) Salmasius, Scaliger, and after them Du Cange, derive the word *casaque* or *cassock* from *caraque*, for *caracalla;* and St Jerome mentions (*Ep.* 128) that the caracalla, with a retrenchment of the capuchin, became an ecclesiastical garment.

CARACAS, a large city of South America, capital of the Republic of Venezuela, and of the department of Caracas, is situated on the declivity of a mountain nearly 2900 feet above the level of the sea, 16 miles S.S.E. of La Guayra, its port on the Caribbean sea. N. Lat. 10. 30., W. Long. 67. 4. Population estimated at about 50,000. The city is finely situated, and has a temperate and healthy though variable climate. The mean temperature of the year is about 72° Fahr., being in the hot season 75°, and in the cold season 66°. The thermometer, however, sometimes rises to 84° or 85°, and at other times descends as low as 51° or 52°. Rain is abundant during the months of April, May, and June, but not so incessant as in other tropical countries; the rest of the year is rather dry. It is much subject to earthquakes, from which it has frequently suffered: in that of 1812, 12,000 persons are said to have perished. Caracas stands on a declivity near four streams, namely, the Guayra, the Anauco, the Caroata, and the Catucho, which, after passing the town, unite, and mingling their waters with those of the Tuy, fall into the ocean thirty-six miles east of Cape Codera. The town is well and regularly built; the streets wide and well paved, crossing each other at right angles. There are several squares in this city, of which the Plaza Mayor, or great square, is the most worthy of notice. The east side is principally occupied by the cathedral, the south by the college, and the west by the public prison. This square is a great market for provisions, fruit, and other articles, and contains a sort of inner square in which are ranges of shops. The Catucho furnishes the city with water, which is supplied to the inhabitants by public fountains, as well as in pipes and reservoirs. The chief public building is the cathedral, which is two hundred and fifty feet in length by seventy-five in breadth, and is supported by twenty-four pillars, without beauty or proportion. There are several parish churches, three monasteries for friars, two nunneries, three hospitals (one of which is for lepers alone), and a theatre. Caracas was founded by Diego Loseda in 1567.

CARACCI, Lodovico, Agostino, and Annibale, three celebrated Italian painters, were born at Bologna in 1555, 1558, and 1560 respectively. Lodovico, the elder, was cousin to the two younger brothers, Agostino and Annibale, and had nearly finished his professional studies before the others had begun their education. From being a reputed dunce at school, he gradually rose by an attentive study of nature and a careful examination of the works of the great masters, preserved at Bologna, Venice, Florence, and Parma, to measure himself with the teachers of his day, and ultimately projected the opening of a rival school in his native place. Finding himself unable to accomplish his design without assistance, he sent for his two cousins, and induced them to abandon their handicraft for the profession of painting. Agostino he first placed under the care of Fontana, retaining Annibale in his own studio, but afterwards sent them both to Venice and Parma, to copy the works of Titian, Tintoretto, and Correggio, on which his own taste had been formed. On their return, the three friends opened an academy of painting under the name of the Incamminati, assisted by an eminent anatomist, Anthony de la Tour, and provided with numerous casts, books, and bassi-relievi, which Lodovico had collected in his travels. From the affability and kindness of the Caracci, and their zeal for the scientific education of the students, their academy rose rapidly in popular estimation, and soon every other school of art in Bologna was deserted and closed. They continued together till, at the invitation of Cardinal Farnese, Annibale and Agostino went to Rome to paint the gallery of the cardinal's palace. The superior praises awarded to Agostino inflamed the jealousy of Annibale, already kindled by the brilliant reception given by the pupils of the Incamminati to Agostino's picture of the *Communion of St Jerome*, and he was dismissed to Parma to paint the great saloon of the Casino. Here Agostino died in 1602, when on the eve of finishing his celebrated painting of *Celestial, Terres-*

trial, and Venal Love. Annibale continued to work alone at the Farnese gallery till the designs were completed; but, disappointed at the miserable remuneration offered by the cardinal, he retired to Naples, where an unsuccessful contest for a great work in the church of the Jesuits threw him into a fever, of which he died in 1609. Lodovico still continued at his academy in Bologna, which, though invited to execute paintings in all parts of the country, he had never quitted except for a short visit to his cousin at Rome. He died in 1619, and was interred in the church of St Mary Magdalene. The works of Lodovico are nearly all to be found in the chapels of Bologna. The most famous are—*The Madonna standing on the moon, with St Francis and St Jerome beside her, attended by a retinue of angels*; pictures of *John the Baptist, St Girolamo, St Benedict, and St Cecilia*, and of the *Limbo of the Fathers.* He was by far the most amiable of the three friends, rising superior to all feelings of jealousy towards his rivals; and though realizing large sums for his productions, yet, from his almost unparalleled liberality to the students of the academy, he died poor. With skill in painting, Agostino combined the greatest proficiency in engraving (which he had studied under Cornelius de Cort), and high accomplishments as a scholar. He died under the deepest remorse for the indecencies which, in accordance with the corrupt taste of the time, he had allowed to creep into his engravings. The works of Annibale are more diversified in style than those of the others, and comprise specimens of painting after the manner of Correggio, Titian, Paolo Veronese, Raphael, and Michael Angelo. The most distinguished are the *Dead Christ in the lap of the Madonna*, the *Infant and St John, St Catharine, St Roche distributing Alms* (now in the Dresden Gallery), and the *Saviour taken down from the Cross in presence of the Virgin*, at present in possession of the Earl of Carlisle. The reputation of Annibale is greatly tarnished by his jealousy and vindictiveness towards his brother, and the licentiousness of his disposition, which brought him to an early grave.

CARACOL (French *caracole*), in the manège, the half-turn which a horseman makes either to the right or left. In the army, the cavalry make a caracol after each discharge, in order to pass to the rear of the squadron.

CARACOL, in *Architecture*, denotes a staircase in a helix or spiral form.

CARACTACUS, a renowned king of the Silures, an ancient British people who inhabited South Wales. Having valiantly defended his country for nine years against the Romans, he was at length defeated, and fled for protection to his stepmother Cartismandua, queen of the Brigantes; but she treacherously delivered him up to the Romans, who carried him to Rome, A.D. 51. When brought before Claudius, he addressed that emperor in a speech at once so noble and pathetic that he immediately obtained a pardon for himself and his friends. (Tac. *Ann.* xii., *Hist.* iii.; Dion Cass. lx.) See BRITAIN.

CARAITES, in ecclesiastical history, a religious sect among the Jews, of which there are still some members existing in Poland, Russia, Constantinople, Cairo, and other places of the Levant. Their distinguishing tenet and practice it is to adhere closely to the words and letter of the Scripture, exclusive of allegories, traditions, and the like.

Leo of Modena, a rabbi of Venice, observes, that of all the heresies among the Jews before the destruction of the temple, there is none now left but that of the *Caraim*, a name derived from *Micra*, which signifies the pure text of the Bible, because of their keeping to the Pentateuch, observing it to the letter, and rejecting all interpretations, paraphrases, and constitutions of the rabbin. Aben Ezra, and some other rabbin, treat the Caraites as Sadducees; but Leo de Juda calls them, more accurately, Sadducees Reformed, because they believe in the immortality of the soul, paradise, hell, the resurrection, and other doctrines which the ancient Sadducees denied. He adds, however, that they were doubtless originally real Sadducees, and sprung from among them. But M. Simon, with more probability, supposes them to have had their origin in this way, namely, that the more rational among the Jews who opposed the dreams and reveries of the rabbin, and used the pure texts of Scripture to refute their groundless traditions, received the name of *Caraim*, which signifies the same as the barbarous Latin *Scripturarii*, that is, persons attached to the text of Scripture. The other Jews gave them the odious name of Sadducees, from their agreement with those sectaries on the head of traditions. Scaliger, Vossius, and Spanheim, rank the Caraites among the Sabæans, Magi, Manichees, and Mussulmans, but by mistake. Wolfgang, Fabricius, and others say that the Sadducees and Esseni were called Caraites in opposition to the Pharisees; while others regard them as the doctors of the law so often mentioned in the Gospel. But these are all conjectures; for Josephus and Philo make no mention of them, which proves that they are more modern than either of those authors. In all probability this sect was not formed till after the collection of the second part of the Talmud, or the Gemera; perhaps not till after the compilation of the Mischna, in the third century. The Caraites themselves pretend to be the remains of the ten tribes led captive by Shalmaneser. Wolfius, from the Memoirs of Mardacheus a Caraite, refers their origin to a massacre among the Jewish doctors under Alexander Jannæus, their king, about a hundred years before Christ; because Simon, son of Schetach, and the queen's brother, making his escape into Egypt, there forged his pretended traditions, and, at his return to Jerusalem, published his visions, interpolating the law after his own fancy, and supporting his novelties from the notices which God, he said, had communicated by the mouth of Moses, whose depositary he was. He gained many followers, and was opposed by others, who maintained that all which God had revealed to Moses was written. Hence the Jews became divided into two sects, the Caraites and Traditionists. Among the first, Juda, son of Tabbai, distinguished himself; among the latter, Hillel. Wolfius reckons not only the Sadducees, but also the Scribes, in the number of Caraites. But the address of the Pharisees prevailed against them all, and the number of Caraites decreased. In the eighth century, Annan indeed retrieved their credit a little; Rabbi Schalomon did the same in the ninth; and they prospered pretty well till the fourteenth; but since that time they have been declining.

But little is known of the Caraites, their works having fallen only into very few hands. Buxtorf never saw more than one, and Selden two; but Trigland says he has recovered enough to speak of them with assurance. He asserts that, soon after the prophets had ceased, the Jews became divided on the subject of works and supererogation, some maintaining their necessity from tradition, whilst others, keeping close to the written law, set them aside; and it was from these last that Caraitism commenced. He adds, that after the return from the Babylonish captivity, in re-establishing the observance of the law there were several practices found proper for that end; and these being once introduced were looked upon as essential, and as appointed by Moses. This was the origin of Pharisaism, while a contrary party who continued to adhere to the letter, founded Caraitism.

The modern Caraites, Leo of Modena observes, have their synagogues and ceremonies. They pretend to be the sole proper Jews, or observers of the laws of Moses, calling the rest by the term *rabbinim*, or "followers of the rabbin." The latter despise the Caraites, refusing to ally or even to converse with them, and treating them as *mamzeim* or bastards, because of their rejecting the constitutions of the

rabbin relating to marriages, repudiations, the purification of women, and the like. This aversion is so great, that if a Caraite should become a rabbinist he would never be received by the other Jews.

The Caraites, however, do not absolutely reject all kinds of traditions, but only such as appear to be not well grounded. Selden, who is very express on this point, observes in his *Uxor Hebraica*, that besides the mere text, they have certain interpretations which they call hereditary, and which are proper traditions. Their theology seems to differ only from that of the other Jews in being purer, and clearer of superstition; and they give no credit to the explications of the Cabbalists, chimerical allegories, nor to any constitutions of the Talmud, but such as are conformable to the Scripture, and may be drawn from it by just and necessary consequences.

Peringer observes of the Caraites in Lithuania, that they are very different, both in aspect, language, and manners, from the rabbinists, with whom the country abounds. Their mother tongue is the Turkish; and this they use in their schools and synagogues. In visage they resemble the Mohammedan Tartars. Their synagogues are placed north and south; and the reason they give for this is, that Shalmaneser brought them northward; so that in praying they must turn to the south, in order to look to Jerusalem. He adds, that they admit all the books of the Old Testament; contrary to the opinion of many of the learned, who hold that they reject all but the Pentateuch.

Caleb, a Caraite, reduces the difference between them and the rabbinists to three points: 1, In that they deny the oral law to have come from Moses, and reject the Cabbala; 2, in that they abhor the Talmud; 3, in that they observe the feasts, as the sabbaths, &c., much more rigorously than the rabbin do; and to these may be added, that they extend the degree of affinity in which marriage is prohibited almost to infinity.

CARAMAN, or KARAMAN, a town of Asia Minor, in the district of Caramania, on the border of an extensive plain at the foot of Mount Taurus. N. Lat. 37. 13., E. Long. 33. 28. It was once the capital of a prosperous kingdom, and contains several remains of its former greatness. It still continues to trade with Smyrna and the other towns of Asia Minor, and to manufacture coarse cloth from the wool obtained in the neighbouring highlands, a considerable portion of which is wrought with cotton into a fabric for the use of the inhabitants. Pop. according to Filcher, 20,000.

CARAMANIA, or KARAMANIA, an extensive district on the southern coast of Asia Minor, comprising on its eastern portion a large tract of fertile table-land, and possessing a coast-line nearly 400 miles long. Its limits do not seem to be very well defined, and are doubly indistinct as not being coincident with the great natural features of the country. The only distinctly marked boundary is the coast-line, consisting of two large rounded headlands, and the intervening bays. It presents a high and precipitous front to the sea. In ancient times it was interspersed with towns of considerable importance; but is now almost deserted, and its inaccessible cliffs are the haunts of pirates. The interior of the country is mountainous, but many of the hills are wooded, and the inclosed valleys afford abundant pasturage. In the eastern district of Adana agriculture is prosecuted with care and success; but elsewhere, owing to the indolence of the inhabitants and the oppressive rule of the Turks, scarcely any attempt is made to develop the resources of the province. It is divided into several administrative districts. The principal towns are Konia, Caraman, and Adana. See Beaufort's *Karamania*.

CARAMNASSA, a river of Hindustan, rising in the British district of Shahabad, within the presidency of Bengal. It is only remarkable in differing from the other streams of India in that Hindus are forbidden to touch it. Pilgrims consequently cross it with the utmost caution, as it is believed that contact with its baneful waters destroys the efficacy of their religious austerities. The legendary ground of the abhorrence in which it is held is variously reported. According to one authority, a certain rajah committed the heinous sins of murdering a Brahmin and marrying a stepmother. A good-natured saint took compassion on the guilty man, and removed his impurity, by collecting water from all the sacred streams in the world and washing him in this powerful bath, which was made on the place whence the Caramnassa (deprived of virtue) has ever since flowed. According to another account, the rajah, relying on his religious austerities and spells, attempted to ascend to heaven, but was opposed by the gods, who suspended him halfway with his head downwards. From his mouth issues a baneful saliva, which infects the waters of the Caramnassa with the baneful qualities attributed to them. The Caramnassa falls into the Ganges on the right side, in Lat. 25. 8., Long. 83. 58.

CARAT, the weight which expresses the degree of fineness of gold. The word is also written *carract*, *carrat*, *karract*, and *karrat*. Its origin is contested; but the most probable opinion is that of Kennet, who derives it from *carecta*, a term which anciently denoted any weight, and came afterwards to be appropriated to that which expresses the fineness of gold and the gravity of diamonds.

Carats are not real determinate weights, but only imaginary. The whole mass, whatever be the weight, is conceived to be divided into twenty-four carats: and as many twenty-fourth parts as it contains of pure gold, it is called *gold of so many carats*, or *so many carats fine*. Thus, gold of eighteen carats is a mixture, of which eighteen parts are pure gold, and the other six of inferior metal.

Carat is also a certain weight which goldsmiths and jewellers use for weighing precious stones and pearls. In this sense the word is supposed by some to be derived from the Greek κεράτιον, a fruit which in Latin is called *siliqua*, the *carob bean*, each of which may weigh above four grains of wheat; and hence the Latin *siliqua* has been used for the weight of four grains. This carat weighs four grains; but they are sometimes lighter than the grains of other weights. Each of these grains is subdivided into $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{8}$, $\frac{1}{16}$, &c. See WEIGHTS and MEASURES.

CARAUSIUS, Emperor of Britain. See BRITAIN, p. 380; and ALLECTUS.

CARAVACA, a town in the province of Murcia, Spain, near a cognominal stream, which is tributary to the Segura. N. Lat. 38. 6., W. Long. 2. 2. It stands on the northern extremity of a fertile plain, the agriculture of which is the principal employment of the inhabitants. Caravaca is commanded by the ancient castle of Santa Cruz, and has an old parish church, with several convents, hospitals, and schools. The hills in the neighbourhood yield several kinds of marble, and in a mountain on the west is the stalactite cavern of Barquilla. Pop. 10,000. The miraculous cross of Caravaca is famous for its healing powers.

CARAVAGGIO, a town of Lombardy, 15 miles S.S.W. of Bergamo, with about 6000 inhabitants. It is celebrated as being the birthplace of the two painters, Polidoro Caldara and Michael Angelo Amerighi, who received their surname of Caravaggio from this town.

CARAVAGGIO, *Michael Angelo Amerighi da*, a celebrated painter, born in 1569 in the village of Caravaggio, from which he took his name. He adopted a style of strange contrasts of light and shadow of colours, laid on with a sort of fury, emblematic of that fierce temper which led the artist to commit a homicide at Rome. To avoid the consequences of his crime he fled to Naples and to Malta, where he was imprisoned for another attempt to avenge a quarrel. Escaping to Sicily, he was attacked by a party sent in pursuit of him, and severely wounded. Being pardoned, he

set out for Rome, where, being arrested by mistake, he expired at a gate of the city in his fortieth year. His best pictures are the *Entombment of Christ*, now in France; *St Sebastian*, in the Roman Capitol; and the *Supper at Emmaus*, in the Borghese Palace. See Painting.

Caravaggio, *Polidoro Caldara da*, a celebrated painter of frieze and other decorations in the Vatican, whose merits were such, that while a mere mortar-carrier to the artists engaged in that work, he attracted the admiration of Raffaello, then employed on his matchless pictures in the Loggie of that palace. Polidoro was born in 1495. His works, as well as those of his master Maturino, have mostly perished, but are well known by the fine etchings of San Bartoli, Alberti, &c. On the sack of Rome by the army of the Constable Bourbon in 1527, Polidoro fled to Naples. Thence he went to Messina, where he was much employed, and gained a considerable fortune, with which he was about to return to Italy, when he was robbed and murdered by his servants in 1543.

CARAVAN (in Arabic *kairawan*, from *karan* to follow, to proceed from place to place; or derived from the Persian *kervan* or *cârvân*, a trader or dealer), is an organized company, either of merchants or of pilgrims, or both, who associate together for the purpose of travelling in greater security. In Eastern countries it is necessary to resort to this mode of travelling in order to escape the dangers arising from the vast deserts that intersect these regions, as well as from wild beasts and bands of marauding Arabs, which are too numerous for single traders or solitary travellers to encounter. Through this kind of intercourse, at once cheap and expeditious, most of the inland commerce of the East is carried on; and the possession of the camel affords facilities for journeying over barren and sandy regions which are inaccessible to wheel-carriages, and the difficulties and privations of which no other beast of burden could endure. The company composing a caravan often consists of several hundred persons, and as many as a thousand camels; and the packing and unpacking of the camels employ a great many hands, some of whom often raise themselves from the condition of servants to the status of merchants who travel on their own account. Any person can, under certain regulations, form a caravan at any time; but generally there are stated periods, which are well known as the regular starting-times for the mercantile journeys. In the hot season the travelling is performed at night. About eight o'clock the whole party put themselves in motion, and continue their journey without interruption till midnight or later. At other seasons they travel all day, only halting for rest and refreshment during the heat of noon. The distances are measured by a day's journey; and from seven to eight hours seem to have been a usual day's journey for caravans (Hornemann, p. 150); so that, estimating the slow and unwieldy gait of a camel at $2\frac{1}{2}$ miles an hour, the average rate of travel will be from seventeen to twenty miles a day.

The earliest caravan of merchants we read of is the itinerant company to which Joseph was sold by his brethren. This caravan was a mixed one, consisting of three classes, Ishmaelites, Midianites, and Medanites, who would seem, like the nomad tribes of Africa in the present day, to have engaged themselves as commercial travellers, and were then on the high caravan-road for the market of Egypt.

Besides these communities of travelling merchants in the East, there are caravans of pilgrims, *i. e.* of those who go for religious purposes to Mecca, comprising vastly greater multitudes of people. Four of these start regularly every year: one from Cairo, consisting of Mohammedans from Barbary; a second from Damascus, conveying the Turks; a third from Babylon, for the accommodation of the Persians; and a fourth from Zibith, at the mouth of the Red Sea, which is the rendezvous for those coming from Arabia and India. The organization of the immense hordes which, on such occasions, assemble to undertake a distant expedition is accomplished in the East by a few simple arrangements, which are the result of long experience. When travelling by night and through extensive deserts, the songs of the Arab servants, and the incessant jingling of innumerable bells fastened to the necks of the camels, enliven the patient beasts, frighten animals of prey, and keep the party together. To meet all the exigencies of the journey, the caravan is placed under the charge of a *caravan bashě*, the chief who presides over all, and under whom there are five leading officers appointed to different departments:—one who regulates the march; a second, whose duties only commence at halting time; a third who superintends the servants and cattle; a fourth who takes charge of the baggage; a fifth who acts as paymaster, &c.; and besides these, there are the officers of the military escort that always accompanies it. The highest functionary is the *hybeer* or guide (from the Arabic verb *hubbar*, to inform or direct), whose services are indispensable in crossing the great deserts, such as that along the coast of the Red Sea, or on the western extremities of Africa. For this office a person of influence is generally chosen, who, besides his known truth and fidelity, possesses an extensive and accurate acquaintance with the whole features of the land. As he has the lives and property of the whole caravan in his power, it is absolutely necessary that he understand the prognostics of the weather, the tracts exposed to the simoom or shifting sands, the exact locality and qualities of the wells, the oases that afford the refreshment and pasture, the situation of hostile or treacherous tribes, and the means of escaping those threatened dangers.

In addition to the overland caravans, there are several naval companies of merchant-pilgrims, which sail from the western ports of the Red Sea to Djidda, and thence travel by land to Mecca.

CARAVANSERAI, in eastern countries, a place appointed for receiving and loading caravans. It is commonly a large square building, with a spacious court in the centre; and under the arches or piazzas that surround it the merchants and those who travel with them take up their lodgings. Over the gates that lead into the court there are sometimes little rooms, which are let out at a high price. Though caravanserais in the East serve in place of inns, there is this radical difference between them, that in general the traveller finds in a caravanserai neither food for himself, nor provender for his cattle. There is no caravanserai, however, without a well or spring of water. The existence of these buildings is chiefly owing to the charity of the Mohammedans; and while there, the persons and the property of travellers are secure. There are also caravanserais where most things may be obtained for money; and as the profits of these are considerable, the magistrates of the cities to whose jurisdiction they belong take care to store them well. At the departure of each caravan, an inspector fixes the price of the night's lodgings, from which there is no appeal.

CARAVANSERASKIER, the steward or keeper of a caravanserai. He keeps an account of all the merchandise sold upon trust, and demands payment of the sums due to the merchants for what has been sold in the caravanserai, on the seller's paying two per cent.

CARAWAY, the fruit or seed of the *Carum Carui*, a biennial umbelliferous plant, with an edible fleshy root about six inches long and as thick as the thumb. The stem rises from two to three feet in height, and produces numerous umbels of small whitish or reddish flowers; and each flower is succeeded by two single-seeded capsules, which are the caraway seeds of commerce. These have a strong peculiar odour, with an aromatic bitter taste; and yield on distillation about 4 per cent. of a volatile oil, on which their properties depend. This aromatic is chiefly used in this country by confectioners; but on the continent it is more largely employed, not only to flavour liqueurs, cakes, &c.,

but also bread, cheese, and various articles of daily food. Its cultivation in Britain is chiefly followed in the counties of Essex and Suffolk, where it is sown on old pasture lands broken up for the purpose, and generally along with coriander and teazle. The coriander, being an annual, yields a crop the first year. The caraway, being a biennial, ripens the second year in July, and the teazles in autumn. If kept clear of weeds, the caraways and teazles would yield smaller crops for several successive years, but it is not found profitable to continue them after the third crop.

CARBON, pure charcoal. See CHEMISTRY.

CARBONARI (*i. e. makers of charcoal*), a designation assumed by the political reformers of middle and lower Italy in this century, intimating that in their number were included the most laborious of the working classes. They consisted, however, of persons of various ranks, who had entered into a secret association for the purpose of emancipating their country. See ITALY.

CARBOY, a large globular bottle of green glass, protected by wicker-work; used chiefly for holding acids and highly corrosive liquids. The average capacity of these bottles is 12 gallons.

CARBUNCLE, a beautiful gem of a rich blood-red colour, found in the East Indies. The carbuncle so highly prized by the ancients was probably a variety of noble garnet.

CARBUNCLE, in *Heraldry*, a charge or bearing consisting of eight radii, four of which make a common cross, and the other four a saltier.

CARCAGENTE, a town in the province of Valencia, Spain. N. Lat. 39. 4., W. Long. 0. 31. It contains about 1500 houses, which are well built, and is inhabited chiefly by an agricultural population, but has a considerable manufacture of linen and woollen stuffs, and silk thread from the silk produced in the neighbourhood. Roman remains have been found in the vicinity. Pop. 7280.

CARCASSONNE, the capital of an arrondissement of the same name in the department of Aude, France, is situated on both sides of the river Aude, 55 miles S.E. of Toulouse. On the right bank of the river, on an elevation, stands the old city, which is connected with the new town on the opposite side by a bridge of ten arches. The city is very ancient, and retains unchanged, to a greater extent perhaps than any other in France, the aspect of a fortress of the middle ages. It is inclosed by double ramparts and towers. A portion of the inner line is attributed to the Visigoths; the rest, including the castle, seems to belong to the eleventh or twelfth century, while the outer circuit has been referred to the latter end of the thirteenth century. The new town is clean, well-built, and flourishing, the streets intersecting each other at right angles. It is surrounded by boulevards occupying the site of its ramparts, and has numerous marble fountains and planted walks. There are several large woollen factories; and not less than 7000 persons of the town and vicinity are engaged in the manufacture of cloth, chiefly exported to the Levant, Barbary, and South America. It has a new and old cathedral, the latter containing the tomb of Simon de Montfort; a town-hall, public library, hospitals, theatre, barracks, commercial college, normal school, &c. Pop. (1851) of town 18,473; of arrondissement 94,970.

CARCERES (*carcer*, a prison), in the Roman circus, were cells or stalls in which the chariots and horses were stationed till the signal for starting was given, when the gates, by an ingenious contrivance, were opened simultaneously. In poetical language the carceres were sometimes designated *claustra, crypta, fauces, ostia, repagula*, &c.

CARD, among artificers, an instrument for combing and disentangling the fibres of wool or flax, freeing them from the coarser parts and from extraneous matter, so as to render them fine and soft for spinning. A card consists of bent wire-teeth inserted in a thick piece of leather, which is nailed by the edges to a piece of board about a foot in length, and half a foot in breadth; and in the middle of one of the longer sides a handle is fixed. They are of various kinds, as hand-cards, stock-cards, &c. These are now in a measure superseded; wool, cotton, &c., being generally carded in mills by teeth fixed on wheels moved by water or steam-power. See WOOL AND ITS MANUFACTURES.

CARDS, *Playing Cards*, oblong pieces of fine pasteboard, commonly three inches and a half long and two and a half broad, on which are painted various points and figures. The invention of playing cards has, by some, been referred to the Romans, but this opinion is undoubtedly erroneous. It is however certain that they were known in Europe at least as early as the year 1275. Though the blocks used for stamping the devices were similar to those that were afterwards employed for the earliest printed books, their application in this way appears to have been long overlooked. Without absolutely affirming that the art of making playing cards really suggested that of printing, it may be noticed as a very remarkable fact, that a period of more than 150 years should have been suffered to elapse before such blocks were applied to the nobler purpose of that art which has done more than any other to advance civilization and ameliorate the condition of mankind.

In the manufacture of playing cards blocks are still employed; but the pips or characters are more commonly produced by the process called stencilling; in which the device is formed by means of an oiled cloth or paper in which apertures are cut, representing spades, diamonds, &c. This is laid above the card, and then the surface of the stencil or pattern is painted over with a brush full of red or black water-colour of rather a thick consistence, or with oil-colour. On removing the stencil, those parts of the card that were exposed will exhibit the corresponding pattern. When perfectly dry, the surface of the card may be polished by simple friction with a soft brush. If it be desired to give to pasteboard the appearance of ivory, this may be effected by covering it with a mixture of size and French white, with a small proportion of clear drying oil. The colour, of course, must not be applied till the pasteboard so prepared be thoroughly dry. The gilding, silvering, or bronzing of any part of the card may be effected by covering the corresponding part of the block with gilder's size, instead of colour, and powdering the surface with gold-dust, &c., by means of a soft dapper. The duty of one shilling per pack on cards sold in 1841 produced the sum of L.9223, 18s.

Among sharpers, divers sorts of false and fraudulent cards have been contrived; as, 1. *Marked* cards, where the aces, kings, queens, knaves, are marked on the corners of the backs with spots of different number and order, either with clear water or water tinged with pale Indian ink. 2. *Breef* cards, those which are longer or broader than the rest; chiefly used at whist and piquet, to enable a person to cut the cards disadvantageously to his adversary, and draw the person unacquainted with the fraud to cut them favourably for the sharper. As the pack is placed either endwise or sidewise to him that is to cut, the long or broad cards naturally lead him to cut them. 3. *Corner bend* denotes four cards turned down finely at one corner, to serve as a signal to cut by. 4. *Middle bend*, is where the tricks are bent two different ways, which causes an opening or arch in the middle, to direct the cutting.

In the learned work of J. G. Immanuel Breitkopf on Playing Cards, we find that they are mentioned in the *Stadtbuch* of Augsburg in 1275; where it is said that the emperor "Rudolph I. amused himself with playing-cards, and other games." They are also noticed in other works as used in Germany in 1286, and in various periods between that and 1384. Tiraboschi mentions their use in Italy as early as 1299, from a manuscript of Pippozzo di Sandro, tom. vi.

1163. The *invention*, therefore, cannot be ascribed to the French in 1390, as Mezérai asserts, although cards were used in France about that year to divert Charles VI., who had fallen into a state of melancholy. The figures of the four suits were regarded as symbolical representations of the four principal classes of men. By the *cœurs* (hearts) are meant the *gens de chœur*, choir-men, or ecclesiastics; and therefore the Spaniards have *copas*, or chalices, instead of hearts. The nobility, or prime military part of the kingdom, are represented by the ends or points of lances or pikes; which, from our misconception of the meaning or resemblance of the figure, were called *spades* in England. The Spaniards have *espadas*, swords, in lieu of pikes, which are of similar import. By diamonds (*carreaux*, square stones, tiles, or the like) are designed the order of citizens, merchants, or tradesman. *Trèfle*, the trefoil-leaf, or clover-grass, corruptly called *clubs*, alludes to the husbandmen and peasants. But how this suit came to be called *clubs* is not easily explained; unless, borrowing the game from the Spaniards, who have *bastos* (staves or clubs) instead of the trefoil, we gave the Spanish signification to the figure of the trefoil. The four kings were David, Alexander, Cæsar, and Charles (names which long continued to be retained on the French cards), and represented the four celebrated monarchies of the Jews, Greeks, Romans, and Franks under Charlemagne. By the queens were intended Argine, Esther, Judith, and Pallas, typical of royal birth, piety, fortitude, and wisdom. *Argine* is an anagram for *regina* or queen. The knaves represented the attendants of knights, for *knave* originally merely meant *servant*. Some suppose that the knights themselves were designed by those cards, because Hogier and Labire, two names on the old French cards, were famous knights at the time when cards began to be used in France.

CARDAMOMS, aromatic seeds furnished by various species of *Amomum* and *Renealmia*, belonging to the natural order Zingiberaceæ, and to the Linnæan class and order Monandria Monogynia. Various kinds are known in commerce, such as the great or Madagascar cardamom, the produce of the *Amomum angustifolium;* the Java cardamom, produced by the *A. maximum;* the round cardamom, *A. Cardamomum;* the Malabar or clustered cardamom, the most esteemed of all, from the *Renealmia Cardamomum;* paradise grains or Malagueta pepper, produced by the *A. Grana Paradisi;* besides several others of inferior note from other members of the same genera. Cardamom seeds are the most grateful of all the aromatics, are largely used to give flavour to aromatic cordials, and enter into the composition of very many of the preparations of drugs used in medicine. With the exception of the grains of paradise, all the kinds of cardamoms are imported in their bluntly triangular somewhat conical shaped leathery capsules, which are full of the small, compressed, rough, trapezoidal seeds in which the flower abounds.

CARDAN, Jerome, a celebrated Italian physician, mathematician, and philosopher, was born at Pavia in 1501. He was a natural son of Facio Cardan, a celebrated jurisconsult of Milan; and in his book *De vitâ propriâ* he represents himself as from his very infancy exposed to the most extraordinary complication of misfortunes. His mother, during her pregnancy, in vain attempted to procure an abortion, and he was delivered only by the cæsarian operation. In the house of his father at Milan, notwithstanding his delicate constitution and tyrannical treatment, he made great progress in mathematics; and though at first he joined the Franciscan order he quickly abandoned the life of the cloister for the eager pursuit of medicine and philosophy. Having studied for a year at Pavia he removed to Padua, where, in the absence of his professor, he was frequently called to conduct the classes of geometry and dialectics, and afterwards received the degree of doctor of medicine. He continued to support himself by his practice for six years at Sacco, where he married Lucia Bandareni, the daughter of a needy Venetian adventurer. Soon afterwards he was withdrawn from his retirement by Archbishop Archinto to lecture on mathematics and medicine at Milan. Induced by extravagant promises from the inhabitants, he accepted the chair of medicine at Pavia, but on the failure of their promises he again returned to Milan. In 1546 he received an invitation from the King of Denmark to fill the chair of medicine at Copenhagen, but declined to quit Milan. About six years later he went to Scotland to visit John Hamilton, archbishop of St Andrews, whom he completely cured of a violent asthmatic affection which had withstood the skill of the most eminent German physicians. He attributed his success to the accuracy with which he calculated the primate's nativity. On his return he removed to Pavia, where he remained till 1652. At the urgent solicitation of several foreign princes, Cardan made a tour through Germany, France, and England, visiting Edward VI., to whom, after a calculation of his nativity, he predicted a long life and reign. From Pavia he removed to Bologna, where he taught until thrown into prison for debt in 1570; but being released in a few months, in order to escape his creditors he removed to Rome, where he was admitted a member of the college of physicians and pensioned by Gregory XIII. He spent the rest of his life without any public employment, and died at Rome in 1576, a few weeks after he had finished his autobiography. Julius Scaliger and De Thou affirm, that having made a calculation of his nativity, he starved himself in order to insure its fulfilment; but this allegation does not rest on sufficient authority. The works of Cardan, consisting of about 122 treatises on physics, mathematics, astronomy, astrology, rhetoric, history, ethics, dialectics, natural history, music, medicine, and anatomy, are of the most varied description, and such a mixture of profound ideas and capricious absurdities as might be expected of a man who piqued himself on being totally unlike all other mortals. The eccentricity of his habits was so great that he was universally reputed mad; and to the violent and revengeful temper which he received from the harshness of his early education he added a firm belief in astrology, and in the constant presence of a familiar spirit which enabled him to hold converse with the other world. Although justly regarded as heterodox by the theologians of the day, there is not sufficient ground for regarding him as an atheist. Most of his works have been collected in an edition edited by Charles Spohn.

CARDASS, an instrument for carding flocks of silk, to make it into cappadine.

CARDERS, persons who card wool, &c. for spinning.

CARDIA, a city at the northern extremity of the Thracian Chersonesus on the eastern shore of the Sinus Melanis or Gulf of Melas.

CARDIAC (Latin *cardiacus*, Greek *καρδιακός*, from *καρδία*, the heart), pertaining to the heart. The word in a substantive form denotes medicine that stimulates the stomach, and animates the spirits; otherwise termed a cordial.

CARDIFF, a municipal and parliamentary borough in the county of Glamorganshire, 170 miles west from London by South Wales railway. N. Lat. 51.28.; W. Long. 3.10. It is situated on the river Taff, about 2 miles from its efflux in the Bristol Channel, and amongst the towns of South Wales ranks next in importance to Swansea. The general aspect of the town is ancient and venerable. The streets are regular,—some of them spacious and handsome,—clean, and well paved. The extension and improvement of the town have been greatly promoted by the construction of the *Bute Ship-Canal and Docks*, accomplished by the late Marquis of Bute at the cost of not less than L.300,000. On passing the dock-gates, which are 45 feet wide, and have a depth of water varying from 17 to 32 feet, vessels enter a capacious basin, which communicates by a lock, 36 feet wide, with an inner dock, extending in a conti-

Cardiff. nuous line 1450 yards long, with a uniform width of 200 feet. It has an area of about 200 acres of water, and is capable of accommodating, in perfect safety, 400 ships of all classes. Quays are built at the sides, comprising more than a mile of wharfs, with ample space for warehouses. To preserve the channel free from deposit, a feeder from the river Taff supplies a reservoir, 15 acres in extent, which can be discharged when necessary so as to deliver at the rate of 100,000 tons of water in an hour.

Immediately contiguous are the Glamorgan canal, the Taff Vale railway, and the South Wales railway, and thus the port of Cardiff becomes the great outlet for the vast mining districts and iron and tin works of the eastern part of Glamorganshire, and possesses facilities for communication with all parts of the kingdom. Besides the extensive exports of iron, tin, coal, and other minerals, Cardiff carries on a considerable trade with Bristol and other ports in the agricultural productions of South Wales. There is daily communication by steam-packets with Bristol, and once or twice in a week with Gloucester and with Swansea. The limits of the port of Cardiff are from the river Rumney on the east to Nash Point on the west. In 1852 there were registered as belonging to the port, 62 sailing and 9 steam vessels, with a burden of 6814 and 366 tons respectively. In the same year, in the coasting trade, there cleared and entered 7185 sailing, and 843 steam vessels, with a burden of 458,943 and 78,010 tons respectively. In the foreign and colonial trade there cleared and entered 2186 sailing vessels, with a burden of 425,500 tons.

Cardiff was in ancient times a place of considerable importance. It possessed a fortified castle, which was surrounded by embattled walls with five entrance gates, a moat, and ramparts. These are believed to have been commenced in 1080, by Jestyn ap Gwrgan, Lord of Glamorgan, and to have been completed on an extended plan by the Norman chief Robert Fitzhamon in 1110. The name is supposed to be derived from *Caer-daff* (fortress on the Taff), or *Caer Didi* (the fort of Aulus Didius). The *Castle* appears to have been long the residence of princes, the seat of judicature, and the scene of many important actions and events. Here, according to tradition, Robert Duke of Normandy, eldest son of the Conqueror, was confined for twenty-six years by order of his brothers William Rufus and Henry I. In 1648, being garrisoned by royalists, it was closely besieged by Oliver Cromwell in person. The bombardment was kept up with great vigour for three days, and possession was at length obtained through the treachery of a deserter from the garrison, who was afterwards hanged by the command of the Protector. Every part of the ancient castle, except an old octagonal keep, has given place to the modern mansion now occupied by the Marquis of Bute. It contains several portraits by Kneller, and one by Vandyck. The castle commands extensive views of the surrounding country.

Cardiff has two parish churches. St John's, about the middle of the town, is an ancient and finely-proportioned edifice, with a noble quadrangular tower, surmounted by pierced battlements and four open Gothic pinnacles. The body of the church may be referred to the thirteenth century, but the tower is obviously of later date. St Mary's is a modern erection, opened in 1843, near the Bute canal. It has two towers in the Norman style of architecture. In this parish a fine old church and many other buildings were destroyed by an inundation in the year 1607. Dissenters of various denominations have places of worship; and in all of them services are conducted both in English and Welsh.

The other public buildings are the town-hall, county gaol, law courts, theatre, infirmary, union poor-house, national, British, and infant schools, and custom-house. The corporation consists of a mayor, 6 aldermen, and 18 councillors. The autumn assizes are held here. Markets are held on Wednesday and Saturday. In conjunction with Cowbridge and Llantrisaint, Cardiff sends one member to the House of Commons. The population is increasing, from the opening of new collieries in the Aberdare Valley; and in 1851 amounted to 18,351.

Cardiganshire. CARDIGANSHIRE, a maritime county in South Wales, is bounded on the north by Merioneth; on the east by Montgomery, Radnor, and Brecon; on the south by Caermarthen and Pembroke shires; and on the west by the Irish Sea. Its greatest length from south to north is about 30 miles, and its greatest breadth from east to west about 40 miles; but these dimensions give a very imperfect idea of its size, as it almost exactly represents in figure a "half boot," the line of the sole being from east to west, with the toe at the extreme west. It possesses an area of 693 square miles, or 443,387 acres, and is therefore the fifth in size of the Welsh counties.

The whole area of this county is occupied by the lower Silurian geological formation. It does not therefore possess mines of coal, or iron, or limestone; but, as if to compensate for this want, it is the richest of all the Welsh counties in its metalliferous lodes. Its lead mines have long been famous; and it was from the profits of his mining speculations, carried on chiefly in this county, that the celebrated Sir Hugh Myddelton was enabled to carry out his gigantic project for supplying London with water, by means of the New River, which he introduced. The Lisburne, Goginian, Cwrn Ystwith, and other mines, still yield largely, and have been sources of great profit to the adventurers. Some of the lead raised is very rich in silver; and in the seventeenth century the quantity of silver obtained was so considerable, that a mint existed for coining it on the spot, by virtue of letters-patent.

Cardiganshire is exceedingly wild and mountainous; but the mountains generally have little of grandeur in their character, and present rather the appearance of a sea of rounded hills, intersected here and there by a valley of greater depth and extent than usual. There is a considerable tract of flat land lying along the sea coast, especially towards the S.W.; but the general aspect of the county is so dreary and desolate, that it has been called, and with good reason, the desert of Wales. In that district it is almost possible to pass in a straight line for 30 miles without seeing a house, or a road, or a human being. The principal mountains are Plymlymon, just within the county boundary on the N.E., rising to the height of 2463 feet, and Tregaron mountain, near Tregaron, in the S.E., 1747 feet in height. Few of the others exceed 1000 feet in elevation. According to well-authenticated tradition, a great portion of what is now the bay of Cardigan was at one time dry land, protected from the incursions of the sea by dikes and dams, similar to those in use at the present time in Holland. It is generally believed that this district was very fertile, and contained no less than 16 towns; and that it was submerged in the year A.D. 520. At low water, remains of apparently artificial structures are still pointed out, as proofs of the truth of the tradition.

The scenery of the vale of Teifi presents views of great beauty and interest, especially as it approaches the sea. There are some fine old ruins on its banks, amongst others those of Kilgerran Castle, near Cardigan, which heighten the interest of the otherwise romantic scenery. The valleys of the Aeron, the Ystwith, and the Rheidol, also present scenes of great beauty, especially the latter, in which is the famous Devil's Bridge, with the falls of the Rheidol, one of the most celebrated pieces of Welsh scenery.

This county abounds in lakes and rivers. The chief of the latter is the Teifi, which rises in a lake of the same name (Llyn Teifi), about 8 miles N.E. of Tregaron; and flowing through the centre of the county, in a N.W. direction, till it reaches Lampeter, becomes from thence the

Cardiganshire. county boundary, separating it from Caermarthen and Pembroke shires; and after a course of about 50 miles from its source, falls into the sea at Cardigan. The Aeron takes its rise in some lakes in a low range of hills called Mynydd Back, and first flowing in a southerly direction, and afterwards nearly due west, falls into the sea at Aberaeron. The Ystwith and Rheidol both rise in Plymlymon, and flowing west, cross the county, falling into the sea at Aberystwith; and the Towy forms the county boundary, separating it from Brecknockshire on the S.E. Besides these streams there are a great number of minor importance.

Cardiganshire has been called the lake county of Wales, an appellation which it well deserves. The most important are Llyn Teifi, Llyn Fyrddyn Fawr, Llyn Egnant, Llyn Gynon, and Llyn Eiddwen; but hardly any of them exceeds three-quarters of a mile in length. They abound in trout, and are now a good deal resorted to by anglers.

There are numerous British and Roman antiquities in this county, consisting of Druidical circles, camps, and stations, and also the remains of a Roman road (the Sarn Helen), about 4 miles from Tregaron.

The climate on the coast is mild and salubrious, but suffers from an excess of rain. The climate of the hill country is cold, wet, and bleak. The cultivated crops consist of wheat, oats, barley, turnips, and potatoes; and in the lower districts on the coast, especially in the neighbourhood of Aberaeron, Llanrhystyd, and Cardigan, good crops are raised; and at the latter, as well as at Lampeter, great improvements are now being effected by means of the government drainage bill, in draining and improving several large estates. The hill district is entirely occupied with wild heathy pastures, which are stocked with the small mountain sheep of the country, and with herds of ponies and cattle, which are annually drafted off by dealers to be fattened in the more fertile districts of Wales or England. Cardiganshire has long been famous for its breed of horses, and for these high prices are obtained from English dealers, who now visit the fairs in considerable numbers. Black cattle, sheep, pigs, butter, barley, oats, woollen manufactures, slates, and lead and lead ore, form the principal articles of export. The farmers are generally a very ignorant, but hardworking and industrious race. In no county of Wales is the blood of the Cymry to be found so unalloyed by any foreign admixture; and it may well be doubted whether the manners and customs, or agricultural practice of the more remote districts, have undergone any change or improvement over those practised in the same districts centuries ago. Some of the sheep farms are of great extent. It is calculated that one-half only of the lands are inclosed.

There is no railway as yet in this county, although a line from Caermarthen to Cardigan has been surveyed, and will probably be shortly formed. There is generally a coach during the summer months every alternate day from Caermarthen to Aberystwith, through Lampeter, and every day from Caermarthen to Cardigan; which are the only public conveyances the county possesses.

The principal towns are, Cardigan, Aberaeron, at which, in consequence of its central situation, the county sessions are held, Aberystwith, Llanbadarn Fawr, Tregaron, Lampeter, and Adpar; which last is the name given to the portion of Newcastle Emlyn, on the Cardigan side of the Teifi. The county returns one member to parliament, and has done so since 1536. The political influence is divided between the families of Powell of Nanters (conservative), and Pryse Loveden of Gogerthan (liberal), one of whom usually sits for the county, and the other for the district. Constituency in 1852, 2235. The average gross rental of the county is estimated at 7s. 5d. per acre. The annual value of real property paying income tax is L.205,328.

The population of the county by the last census was 70,796, giving an average of 102 persons to a square mile, or 6·3 acres to each person. Of the total number, 32,961 were males, and 37,835 females, showing a great disproportion of the sexes, in the great excess of females, a state of population which prevails only in two other of the Welsh counties, Pembroke and Caermarthen. It may be perhaps accounted for by the emigration of men to the mining districts, especially Glamorganshire, where the excess of males would just balance the deficiency in the three counties named. The number of inhabited houses in 1851 was 14,978, uninhabited 544, and building 70, giving an average of 22 inhabited houses to a square mile, and 4·7 persons to each house. The following table gives the census returns for the last 50 years:—

YEARS.						Increase of population per cent. in fifty years.
1801.	1811.	1821.	1831.	1841.	1851.	
42,956	50,260	57,784	64,780	68,766	70,796	65

It is calculated that the condition of about one-fourth of the whole population is that of labourers, servants, &c. About thirteen per cent. live by agriculture, and about eight per cent. by trade, while upwards of 2000 persons possess independent means, and about 400 follow professions.

In 1847 the total number of children of the working classes at day schools within the county was 3885. The total number of schools was 101, of which 37 were church or national, with 1643 scholars; 49 private or adventure, with 1617 scholars; 2 British schools, with 136 scholars; 5 dissenting, with 307 scholars; and 8 dame schools, with 182 scholars. The average annual income of each school was only L.25, 0s. 4¾d., and the average annual income of the teachers, from all sources, only L.23, 16s. 7¾d. The total number of Sunday schools was 206; of which 55 were Church of England schools, with 4074 scholars; 18 Baptist, with 2025 scholars; 70 Calvinistic Methodist, with 13,776 scholars; 44 Independent, with 5483 scholars; and 19 Wesleyan Methodist, with 1773 scholars. In 159 of those schools instruction was given in the Welsh language only; in 10 in the English language only; and in 37 in both tongues. It is calculated that not more than 3000 of the whole population of the county use the English language, there being upwards of 67,000 who habitually use the Welsh language.

The women in Cardiganshire all dress in the picturesque costume of Wales, and have their heads surmounted by the high-crowned broad-brimmed hat. Some of the customs are curious. On the occasion of a marriage, a *bidder* goes from house to house inviting the inmates to the wedding. It is expected that all the guests are to bring presents of money and provisions. The marriage always takes place on a Saturday; but the guests assemble on Friday with their presents. All these are set down on paper, that, if demanded, they may be repaid; but this seldom happens. The furnishing of the bride is also brought home on this day. On Saturday ten or twenty of the man's friends who are best mounted go to demand the bride. She is placed on a horse, behind her father, who rides off as fast as he can. He is soon, however, overtaken. Presents continue to be received on Saturday and Sunday, and on Monday they are sold, and sometimes realize with the money received L.50 or L.60.

This was one of the counties involved in the singular disturbances known as the Rebecca riots.

It is in the diocese of St David's; and at Lampeter there is a college for the education of the Welsh clergy.

Cardigan. CARDIGAN, the capital of the county of the same name, a market and borough town. It is situated in the S.E. of Cardigan bay, at the mouth of the Teifi, which there divides the county from Pembrokeshire. The houses are

mostly constructed of slate rock; and the town presents a singular appearance, from the custom which prevails of annually washing the whole houses, roofs as well as walls, with lime. There is a large and fine church about 200 years old, and there are several places of worship belonging to the different dissenting bodies. There is a handsome national school; but the other public buildings are of a very simple character.

The corporation consists of a mayor, four aldermen, and twelve councillors. The borough, in conjunction with Aberystwith, Lampeter, and Adpar, has returned one member to parliament since 1836. Constituency in 1832, 672; in 1847, 662. The assessed taxes yield annually L.1478, and the annual value of real property paying income tax is L.29,864. There is a weekly market on Wednesday, and several fairs in the course of the year. The assizes are held here.

The port of Cardigan is capable of being entered at high spring tides by vessels drawing 15 to 18 feet of water. In 1853 there entered the harbour, with cargoes, 370 vessels engaged in general trade, having a tonnage of 9967 tons, besides a great number of vessels engaged in carrying limestone, of which no account is kept. During the same period there left the port, with cargoes, 38 vessels, of 1155 tons burthen, besides a great number laden with slates, of which no account is kept. The principal imports are timber, coal-culm, and general merchandise.

CARDINAL (Latin *cardinalis*), chief, principal, pre-eminent, or fundamental, is an appellation given to things on account of their pre-eminence. The word is formed from the Latin *cardo*, a hinge; as denoting the fundamental point on which things turn. Thus justice, prudence, temperance, and fortitude, were denominated by the Pagans the four *cardinal virtues*, as being the basis of all others.

Cardinal Numbers, in *Grammar*, are the numbers one, two, three, &c.; in distinction to the ordinal numbers, first, second, third, fourth, &c.

Cardinal Points, in *Cosmography*, are the four intersections of the horizon with the meridian and the prime vertical circle, or *North* and *South, East* and *West.* The cardinal points, therefore, coincide with the four cardinal regions of the heavens, and are 90° distant from each other. The intermediate points are called *collateral points.*

Cardinal Points, in *Astrology*, are the rising and setting of the sun, the zenith, and nadir.

Cardinal Signs, in *Astronomy*, are Aries, Libra, Cancer, and Capricorn.

Cardinal Winds are those that blow from the cardinal points.

Cardinal, an ecclesiastical prince in the Romish Church, who has a voice in the conclave at the election of a pope, who is taken from their number. Some say that the cardinals were so called from the Latin *incardinatio*, which signifies the adoption in any church of a priest of a foreign church, driven thence by misfortune; and that the use of the word commenced at Rome and Ravenna, which, as the revenues of the churches of those cities were very great, became the common refuge of the unhappy priests of all other churches.

The cardinals compose the pope's council. They are divided into three classes or orders, containing 6 bishops, 50 priests, and 14 deacons, and making in all 70, who constitute what is called the *sacred college.* The cardinal bishops, who are as it were the pope's vicars, bear the titles of the bishoprics assigned to them, and the rest take such titles as are given them. The number of cardinal bishops has been fixed, but that of cardinal priests and deacons, and consequently the sacred college itself, is always fluctuating. Till the year 1125 the college consisted of 52 or 53, and the council of Constance reduced them to 24; but Sixtus IV. raised them again to 53, and Leo to 65. Thus, as the number of cardinal priests was anciently fixed at 28, new titles were to be established as new cardinals were created.

In the Vatican there is a constitution of Pope John which regulates the rights and titles of the *cardinals*, and declares, that as the pope represents Moses, so the cardinals represent the 70 elders, who, under the pontifical authority, decide private and particular differences.

Cardinals, in their first institution, were only the principal priests, or incumbents, of the parishes of Rome. In the primitive church the chief priest of a parish, who immediately followed the bishop, was called *presbyter cardinalis*, to distinguish him from the other petty priests, who had no church or preferment. The term seems to have been first applied to them in the year 150; but some say that this took place under Pope Silvester, A.D. 300. These cardinal priests were alone allowed to baptize and administer the eucharist. When the cardinal priests became bishops, their cardinalate became vacant, as they were then supposed to be raised to a higher dignity. Under Pope Gregory, cardinal priests and cardinal deacons were only such priests and deacons as had a church or chapel under their particular care; and this was the original use of the word. Leo IV. in the council of Rome held in 853, calls them *presbyteros sui cardinis;* and their churches, *parochias cardinales.* The cardinals continued on this footing till the eleventh century; but as the grandeur and state of his holiness then became exceedingly augmented, he wished his council of cardinals to make a better figure than the ancient priests had done. It is true that they still preserved their ancient title, but the thing expressed by it ceased to exist. It was a long time, however, before they had the precedence over the bishops, or got the election of the pope into their hands; but when they once became possessed of those privileges, they soon got the red hat and purple; and growing still in authority, became at length superior to the bishops, by the sole quality of being cardinals.

Du Cange observes, that there were originally three kinds of churches; the first or genuine churches were properly called *parishes;* the second, which were chapels joined to hospitals, and served by deacons, were denominated *deaconries;* the third were simple *oratories*, where private masses were said, and were served by local and resident chaplains. He adds, that to distinguish the principal or parish churches from the chapels and oratories, the name *cardinales* was given to them. Accordingly, parish churches gave titles to cardinal priests; and some chapels also, at length, gave the title of *cardinal deacons.*

Others observe, that the term *cardinal* was given not only to priests, but also to bishops and deacons who were attached to certain churches, to distinguish them from those who only served them *en passant*, and by commission. Titular churches, or benefices, were a kind of parishes, or churches, assigned each to a cardinal priest, with some stated district depending on it, and a font for administering baptism, in cases where the bishop himself could not administer it. These cardinals were subordinate to the bishops; and accordingly, in councils, particularly that held at Rome in 868, subscribed after them.

It was not, however, only at Rome that priests bore this name; for we find that there were cardinal priests in France. Thus, the curate of the parish of St John de Vignes is called in old charters the *cardinal priest* of that parish. The title of *cardinal* is also given to some bishops, *quatenus* bishops, as for instance, those of Mentz and Milan. The Archbishop of Bourges is also, in ancient writings, called *cardinal;* and the church of Bourges a *cardinal church.* The abbot of Vendôme used to style himself *cardinalis natus.*

According to Onuphrius, it was Pope Pius IV. who first enacted, in 1562, that the pope should be chosen only by the senate of cardinals; whereas till that time the election

was by all the clergy of Rome. Some say the election of the pope rested in the cardinals exclusively of the clergy, in the time of Alexander III. in 1160. Others go higher still, and affirm that Nicholas II. having been elected at Sienna, in 1058, by the cardinals alone, occasioned the right of election to be taken from the clergy and people of Rome, leaving them only that of confirming him by their consent, which was at length, however, taken from them. (See his decree for this purpose, issued in the Roman council of 1059 in Hardouin's *Acta Conciliorum*, tom. vi. part i. p. 1165.) It appears, indeed, that the cardinals who had the right of suffrage in the election of his successors were divided by this pontiff into *cardinal bishops* and *cardinal clerks*, meaning by the former the seven bishops who belonged to the city and territory of Rome, and by the latter the *cardinal presbyters*, or ministers of the 28 Roman parishes or principal churches. To these were added in process of time, under Alexander III. and other pontiffs, new members, in order to appease the tumults occasioned by the edict of Nicholas II.

At the creation of a new cardinal, the pope performs the ceremony of opening and shutting his mouth, which is done in a private consistory. The shutting his mouth implies the depriving him of the liberty of giving his opinion in congregations; and the opening his mouth, which is performed fifteen days after, signifies the taking off this restraint. However, if the pope happens to die during the time a cardinal's mouth is shut, he can neither give his voice in the election of a new pope, nor be himself advanced to that dignity.

The dress of a cardinal is a red soutane, a rochet, a short purple mantle, and a red hat. The cardinals began to wear the red hat at the council of Lyons in 1243. The decree of Pope Urban VIII., by which it is appointed that the cardinals be addressed by the title of *eminence*, is of the year 1630; till then they were called *illustrissimi*.

When cardinals are sent to the courts of princes, it is in quality of legates *a latere;* and when they are appointed governors of towns, their government is called by the name of *legation*.

Cardinal has also been applied to secular officers. Thus the prime ministers in the court of the Emperor Theodosius were called *cardinales*. Cassiodorus, lib. vii. formul. 31, makes mention of the cardinal prince of the city of Rome; and in the list of officers of the Duke of Bretagne, in 1447, we meet with one Raoul de Thorel, cardinal of Quillart, chancellor, and servant of the Viscount de Rohan, which shows it to have been an inferior quality.

CARDIOID, an algebraic curve, so called from its resemblance to a heart.

CARDONA, a town of Spain, in the province of Catalonia, with 2800 inhabitants. It occupies the summit of a hill near the banks of a small river, the Cardonera, a branch of the Lobregat. It is remarkable for the famous mountain of rock salt in its vicinity. It forms a mountain mass in the head of a valley, and is covered by a thick bed of a reddish brown clay, and apparently rests on a yellowish gray sandstone, that slightly effervesces with acids. It is rather, according to Dr Traill (*Geolog. Trans.*), a valley filled with salt than a mountain of that material as commonly stated. The salt is generally more or less translucent, but large masses of it are quite transparent; and pieces cut from it are worked by artists in Cardona, into images, crucifixes, and many articles of an ornamental kind. N. Lat. 41. 57., E. Long. 1. 37.

CARDUCHI (the modern Kúrds), ancient warlike mountain tribes, who inhabited the hill country lying between Mesopotamia and the great table-land of Persia. They uniformly baffled all the attempts made at different times by the Persian monarchs to subdue them. The Ten Thousand on their retreat after the battle of Cunaxa suffered severely as they passed through the difficult country of the Carduchi. A complete account of their modes of life, habits, and customs, will be found in the opening chapters of the fourth book of Xenophon's Anabasis, in which their skill in archery is thought worthy of special notice.

CAREENING, the bringing a ship to incline on one side, in order to cleanse, repair, pitch, or caulk the opposite side.

CAREER, in the manège, a place inclosed with a barrier, in which they run the ring. It also denotes the race itself.

Career, in falconry, a flight or tour of the falcon, about 120 yards.

CARET (Latin *caret*, there is wanting, from *careo*), in writing, a character marked thus ʌ, to indicate that something added on the margin, or interlined, should be read in that place.

CAREW, George, was the brother of the author of the *Survey of Cornwall*, and like him passed his early life in studying at Oxford, at the Inns of Court, and in continental travel. At the recommendation of Queen Elizabeth, who conferred on him the honour of knighthood, he was appointed secretary to Sir Christopher Hatton, and afterwards, having been promoted to a mastership in chancery, was sent as ambassador to the king of Poland. In the reign of James he was employed in negotiating the treaty of union with Scotland, and for several years held the office of ambassador to the Court of France. On his return he wrote a *Relation of the State of France*, with sketches of the leading persons at the Court of Henry IV. It is written in the classical style of the Elizabethan age, and has been appended by Dr Birch to his *Historical View of the Negotiations between the Courts of England, France, and Brussels, from* 1592 *to* 1617. During his residence in France, he communicated much important information to the historian De Thou in regard to the affairs of Poland, which has been incorporated into that author's History of His Own Times. He died about the year 1613.

Carew, *George*, Earl of Totness, and Baron Carew of Clopton, Warwickshire, was born in 1557. After completing his studies at Oxford, he joined the army, and held an important command in the Irish wars against the Earl of Desmond and the rebels. He was successively appointed governor of Askeaton castle, lieutenant-general of artillery, and after a successful expedition to Cadiz (1596) lord-president of Munster, treasurer to the army, and ultimately one of the lords judges of Ireland. When he entered on his duties, the whole country was in open rebellion; but by prudent and vigorous policy, backed by his own intrepidity in the field, he soon reduced the rebels to submission. His greatest exploit was the capture of Dunboy castle, an event which disappointed the Spanish allies, and in reality put an end to the war. For his services in Ireland he was made governor of Guernsey, and raised to the peerage. He was afterwards made privy-councillor to James VI., and died at London in 1629. Carew wrote an account of the wars in Ireland in a book called *Hibernia pacata*, published after his death; and made several collections for the history of Henry V., which were afterwards digested into Speed's *History of Great Britain*.

Carew, *Richard*, author of the *Survey of Cornwall*, was born in 1555. At an early age he became a distinguished student of Christ Church, Oxford, and when only fourteen was chosen to dispute extemporaneously with Sir Philip Sydney, in presence of the Earls of Leicester, Warwick, and other noblemen. From Oxford he removed to the Middle Temple, where he spent three years, and then went abroad. On his return he was appointed sheriff of Cornwall, and published his Survey of the county, a work which enjoyed a high reputation, and has been several times reprinted. His other works are entitled, *The Examination of Men's Wits*, a translation from the Italian, part of which is said to have been executed by his father; *The True and Ready*

Way to learn the Latin Tongue, a tract included in Hartlib's book on the same subject; and *A Translation of the first Five Cantos of Tasso's Gierusalemme*. He died in 1620.

CAREW, *Thomas*, an English poet, was born about the year 1589. He studied at Oxford, and on the completion of his course was made gentleman of the privy chamber to Charles I. At court he was highly esteemed for the vivacity of his wit and the elegance of his manners; and his poetical tastes gained him the friendship of Ben Johnson, Sir William Davenant, and other celebrated literary men. He wrote several sonnets, amorous pieces, and masques, which were set to music by Henry Lawes and other eminent masters. His best known work is a masque called *Cœlum Britannicum*, performed by the king and several of the nobles at Whitehall on Shrove Tuesday 1633. He died in the prime of life about the year 1639.

CAREY, HENRY, a humorous poet and musical composer, was an illegitimate son of George Savile, Marquis of Halifax, and was born about the end of the seventeenth century. He studied music under Lennert, Roseingrave, and Geminiani, but never attained to excellence in the higher departments of composition. His ballads and songs, however, were exceedingly popular at the time. He wrote several dramatic pieces for Covent Garden theatre, among which may be mentioned a burlesque tragedy called *Chrononhotonthologos*; a farce called the *Honest Yorkshireman*; two interludes, called *Nancy* and *Thomas and Sally*; and two burlesque operas, called *The Dragon* and *Margery or the Dragoness*. His songs were collected and published by himself in a work called *The Musical Century*; and the tune of one of them, beginning "Of all the girls that are so smart," still survives in the popular air of *Sally in our Alley*. Carey, who seems to have been of an amiable but exceedingly irritable disposition, put an end to his life in 1744, probably in a fit of despondency caused by the malicious attacks of rival composers.

CAREY, *William*, a celebrated Baptist missionary and oriental scholar, was born at Paulerspury, Northamptonshire, in 1761. When a youth he wrought with his father, who was a shoemaker, and before he was twenty years of age he joined the Baptists, and devoted a large portion of his time to village preaching. In 1787 he became pastor of a Baptist congregation in Leicester, and five years after was chosen by a Baptist missionary association to proceed to India as their missionary. On reaching Bengal, Carey and his companions lost all their property in the Hooghly; but having received the charge of an indigo factory at Malda, he was soon placed in a favourable position for prosecuting the work of translating the Bible into Bengalee. In 1799 he quitted Malda for Serampore, where he established a church, a school, and a printing press for the publication of the Scriptures and philological works. In 1801 Carey was appointed professor of oriental languages in a college founded at Fort-William by the Marquis of Wellesley, and soon after received a doctor's degree from his native country. From this time till his death he devoted himself to the preparation of numerous philological works, consisting of grammars and dictionaries in the Mahratta, Sanscrit, Punjabee, Selinga, Bengalee, and Bhotanta dialects. The Sanscrit dictionary was unfortunately destroyed by a fire which broke out in the printing establishment. From the Serampore press there were issued no fewer than 24 different translations of the Scripture, which were all edited by Dr Carey. He died in 1834.

CARGADORS, the Dutch name for those brokers who find freight for ships, and give notice to merchants of the ships that are ready to sail, &c.

CARGILL, DONALD, one of the leaders of the Covenanters, was born in 1610. He was educated at St Andrews, and afterwards attached himself to the Protesters. He was soon after appointed one of the ministers of Glasgow, and made himself obnoxious to government by his open resistance to their measures. Compelled to remain at a distance from his charge, he ventured back to celebrate the communion and was arrested, but was liberated at the instance of some of his private friends. He was afterwards wounded at the battle of Bothwell Bridge, and fled to Holland, where he remained a few months. On his return he joined Richard Cameron in publishing the Sanquhar declaration (see BRITAIN, p. 432), and was immediately after apprehended. He was tried at Edinburgh for high treason, and beheaded on the 27th July 1681.

CARGO (Spanish *carga* or *carcazon*, a load), the goods, merchandise, or other effects with which a ship is laden. The person employed by merchants to proceed with the ship in charge of the cargo, and to dispose of it to the best advantage, is called the *super-cargo*.

CARIA, a maritime province in the S.W. corner of Asia Minor. The boundaries of the kingdom, as possessed by the original Carians, seem to have undergone rapid changes with the advancement of Dorian and Ionian colonization on the coast. Accordingly the earlier geographers assign it a much larger territory than those who wrote at a later period. The principal encroachment seems to have been made in the north, where the Ionian settlers dispossessed the Carians entirely of the plain between the Messogis range and the Mæander, which from that time forward became the northern boundary of Caria. The Dorian immigrants contented themselves with seizing on the islands and part of the sea-coast, which however still remained as the great natural boundary of the Carian province. The eastern frontier is distinctly marked by the range of Mount Cadmus; and the river Calbis, near the left bank of which stood Calynda, the frontier town according to Strabo, sufficiently divides the province from Lycia on the south. The interior of the country consisted chiefly of a fertile plain, inclosed by the Mæander and the Messogis hills, and several smaller valleys inclosed by the ridges which stretch from the eastern boundary in a south-westerly direction to the sea, and are prolonged in the various peninsulas and islands on the coast. Beyond the cultivation of the olive and vine, and the tending of their flocks of sheep on the highlands, the Carians paid little attention to agricultural pursuits. They served like the modern Swiss as mercenaries to almost all their more powerful neighbours; and while indifferent to everything but their pay, they were generally planted in the front of the battle, and fought with the greatest bravery. Their mercenary character in ancient times, however, gave rise to several proverbs in which cheapness, rudeness, and treachery were associated with the Carian name. *In Care periculum* indicated headless daring. *Cum Care Carissa* was a common mode of designating clownish behaviour. The islands on the coast were too widely scattered, and too much exposed to the powerful maritime states in the neighbourhood, to remain long in connection with an oppressed people on the mainland; but must have afforded admirable shelter to the Carians when they were the pirates of the Ægean. Syme alone remained faithful to the continental interest. Of the Carian ancestry very conflicting accounts have come down to us from antiquity. They piqued themselves in being an aboriginal people, but their Cretan rivals gloried in affirming that they had been once subjects of the great Minos. They seem originally to have been extensively scattered over the islands of the Ægean, and to have been confined within, if not actually driven to, their possessions on the mainland by the flood of Dorian and Ionian colonies, which seized on every convenient point for maritime settlements. According to Thucydides, their characteristic armour was to be seen in the graves of Delos; while vestiges of a totally distinct, although perhaps an allied people, were to be found

on the mainland which afterwards went by their name. If these native Pelasgi were dispossessed by the Carian fugitives, they themselves shared the same fate at the hands of the Dorian and Ionian colonies, and the enterprising Rhodians, who stripped them respectively of Cnidus and Halicarnassus, Mycale and Miletus, Peræa, and what was afterwards called the Rhodian Chersonese. Notwithstanding the presence of these invaders in their territory, the Carians still enjoyed a large measure of independence, retaining their own dialect, and preserving their own political constitution. Their Chrysoræum or convention met in the interior at the temple of Zeus Chrysoræus and settled their private affairs, even after the surrounding districts had yielded to a foreign yoke. The Persians, who, not without a protracted contest, reduced them to obedience after the Ionian revolt, pushed their conquests no farther than to establish a line of native princes, who ruled at Halicarnassus, and were dependent on the Persian crown. On the approach of Alexander the Great, Ada the rightful queen vindicated her claim to Grecian descent by detaching herself from the Persian interest, and was rewarded for her allegiance with the throne of Caria. Her descendants did not fare as well from the subsequent Macedonian princes, who established themselves in her dominions, and paved the way for their occupation by Antiochus the Great. On the rise of the Roman power in Asia Minor, the district of Caria was dismembered and partitioned between Eumenes, king of Pergamus, and the Rhodians, and soon after incorporated with the Roman province of Asia. On the fall of the Eastern empire it passed into the hands of the Turks.

CARIACO, a seaport-town of South America, in the republic of Venezuela and county of Cumana. It is situated in a large plain near the head of the gulf of the same name, 40 miles E.N.E. of Cumana. The climate is unhealthy and the town small, but it has some trade in cotton. Pop. 7000; N. Lat. 10. 30., W. Long. 63. 40.

CARIBBEAN SEA, that part of the Atlantic Ocean lying between the coasts of Central and South America and the islands of Cuba, Hayti, Porto Rico, and the Leeward and Windward Islands.

CARIBBEE ISLANDS, in its more extended sense, is applied to the whole of the West Indies; but strictly, it only comprehends that cluster of islands stretching from Porto Rico to the coast of South America, and known as the Leeward and Windward Islands. See West Indies.

CARICATURE (Italian *caricatura*, from *carica*, a load), a figure or a description in which beauties are concealed and blemishes exaggerated, but still so as to preserve a resemblance to the object.

CARICOUS, an epithet given to tumours that bear a resemblance to the form of a fig.

CARIGNANO, a town of Northern Italy, kingdom of Sardinia, and province of Turin, is situated on the left bank of the Po, here crossed by a wooden bridge 11 miles south of Turin. It is surrounded by old walls, and has a handsome church, a communal college, and several convents. Population about 8000, principally engaged in the spinning of silk and the manufacture of confectionery. The royal family name is derived from this place.

CARILLON, the French term for a chime of bells.

CARIMATA, an island in the Eastern Archipelago, lying off the west coast of Borneo, in E. Long. 108. 54., S. Lat. 1. 36. It is woody and mountainous, with a peak in the centre rising to the height of 2000 feet.

CARINA (Latin, *the keel of a ship*, or *a ship*), in the *Ancient Architecture*, was sometimes used to denote the vaulted portion of a building, from its resemblance to the form of a ship; as we designate the central vault of a Gothic cathedral the *nave*, from the Latin *navis*, a ship. For the same reason a place in Rome between the Cœlian and Esquiline hills was called *Carinæ*.

CARINI, a town of Sicily, in the intendancy of Palermo, on a rivulet of the same name, 12 miles W.N.W. of Palermo. It is pleasantly situated on an elevation, and is a neat clean town, with a Gothic castle, several churches, and other public buildings. Pop. 7000. Near it are ruins of the ancient Hyccara.

CARINTHIA. See Austria.

CARISBROOKE, a village and parish in the Isle of Wight, formerly a market-town, and capital of the island. It is situated at the base of a steep conical hill, on which stands its castle, one mile S.W. of Newport. The original fortress is supposed to have been built by the Saxons as early as the sixth century. Various additions were made to it at different times, the last by Queen Elizabeth, when the outer walls which still remain were made to inclose about 20 acres; and the old fortress, with its keep, covers an area of two acres. Here Charles I. was confined for thirteen months previous to his being delivered up to the parliamentary forces. Within the walls is a remarkable well 200 feet in depth. The church is of great antiquity, and adjoining it are some remains of a Cistercian priory. Pop. of parish (1851) 6712.

CARK (Saxon *carc*), care, distress, anxiety.

CARLETON, Sir Dudley, was born in Oxfordshire in 1573, and educated at Christ Church College, Oxford. He went in a diplomatic capacity to the Low Countries when King James resigned the cautionary towns to the States; and he was afterwards employed for twenty-nine years as ambassador to Venice, Savoy, and the United Provinces. Charles I. created him Viscount Dorchester, and appointed him one of his principal secretaries of state, an office which he held till his death in 1651. He published several works, consisting chiefly of speeches, letters, and other productions on political subjects. The most valuable was published after his death, and consist of a selection of letters to and from Sir Dudley Carleton during his embassy to Holland, from January 1616 to December 1620, 4to, 1757.

CARLI, Gian-Rinaldo, Count of, a celebrated Italian writer on antiquities and economics, was born at Capo d'Istria, in 1720. He was early distinguished for the extent and variety of his acquirements; for at the age of twenty-four he was appointed by the senate of Venice to the newly-established professorship of astronomy and navigation in the University of Padua, and intrusted with the superintendence of the Venetian Marine. After filling these offices for seven years with great credit, he resigned them in order to devote himself to antiquities and general economics. In 1754 he published the first volume of his great work *Delle Monete, e delle Instituzione delle Zecchi d'Italia*. This laborious work, which in nine years had increased to seven volumes 4to, was completed in 1785. An edition in 19 vols. 8vo appeared also at Milan from 1784 to 1794. In his speculations on the Balance of Trade, though he did not anticipate Adam Smith on this point, he was the first continental philosopher who maintained that what is termed the Balance of Trade between two nations is no criterion of the prosperity of each; for that both may be gainers by their reciprocal transactions, on the same principles as developed by Smith. His merits were appreciated by the discerning Leopold of Tuscany, afterwards Emperor of Germany, who in 1765 placed Count Carli at the head of the Council of Public Economy, and of the Board of Public Instruction. The duties of these honourable offices he continued to discharge for some years; but for several years before his death he was relieved from their toils; retaining, however, their emoluments, as a reward for his important services. It was during the leisure thus afforded that he completed and published his very valuable *Antichità Italiche*, Milan, 5 vols. 4to, 1788–91, in which the literature and arts of his country are ably discussed. It is highly praised for its research and erudition by Tiraboschi, Bossi, and

Ugoni. The accomplished author died at Milan in February 1795. (T. S. T.)

CARLINE, or CAROLINE THISTLE. This plant is said to have been discovered by an angel to Charlemagne, to cure his army of the plague; whence its denomination.

CARLINE, or *Caroline*, a silver coin current at Naples, worth about 4d. sterling.

CARLINES, or CARLINGS, in a ship, two pieces of timber ranging fore and aft from one beam to another directly over the keel. On these rest the ledges to which the planks of the deck are fixed. Carline knees are timbers lying athwart the ship, from the sides to the hatchway, and serving to sustain the deck.

CARLINGFORD, a seaport-town of Ireland, in the county of Louth, situated on a bay to which it gives name, ten miles from Dundalk. It is an inconsiderable town, and its inhabitants, amounting in 1851 to 887, are chiefly engaged in the oyster fishery in the bay. Previous to the union, it returned two members to the Irish parliament.

CARLISLE, a parliamentary and municipal borough, the capital of Cumberland, 301 miles N.N.W. from London; N. Lat. 54. 54., W. Long. 2. 55. It is situated on an eminence nearly inclosed by three streams, the Eden, the Caldew, and the Peteril, which are crossed by several handsome bridges. It is supposed to be of British origin, and seems to have been a Roman station, though not one of great importance. It was first fortified about the time of Agricola, but the erection of the castle does not date beyond the time of William Rufus. In border warfare Carlisle suffered severely; it was taken by David King of Scots, and afterwards besieged unsuccessfully by William the Lion. In the civil wars it declared for Charles I., and suffered from the armies of the Commonwealth. In 1745 it surrendered to Prince Charles Stuart; and, on being retaken by the Duke of Cumberland, was the scene of many cruel severities upon the conquered. After the junction of the two crowns it fell into decay, but has made rapid increase during the present century. Pop. (1801) 10,221; (1821) 15,476; (1841) 23,012; (1851) 27,484.

The principal business of the town consists in the manufacture of cotton goods and ginghams; and a considerable profit is derived from the coasting trade of Port-Carlisle on the Solway Frith, and of Bowness which communicates with Carlisle by a ship canal 11 miles long. The vessels belonging to the port in 1852 numbered 35, with a tonnage of 2023, besides two steam vessels of small burden. The coasting-trade (1852) employed 243 sailing and steam vessels, which entered with a tonnage of 32,554; while 442 cleared, with a tonnage of 41,155.

The municipal government of Carlisle is vested in a mayor, 10 aldermen, and 30 councillors. Since Edward I. it has returned two members to parliament. It is the see of a bishop (income L.3000), and contains an ancient cathedral in various styles of architecture, in the interior of which is a monument erected to Dr Paley, who was archdeacon of Carlisle. Besides the cathedral, there are four other Established churches, and several places of worship for Independents, Presbyterians, Baptists, Wesleyans, &c. Its educational establishments comprise the National, British, Fawcett, (so called from Rev. John Fawcett, late of St Cuthbert's Church,) industrial and private schools; its scientific and literary institutions include two literary associations, a mechanics' institute, public library, news-rooms, &c.; its charities consist of an infirmary, fever hospital, dispensary, and humane society. A county-court is held at Carlisle. The court-houses were erected at a cost of L.100,000. Among the more recent buildings, the custom-house, the fish-market, the news-room, and the railway station, have added considerably to the improvement of the town. A market is held on Wednesdays and Saturdays, and fairs in August and September. A considerable part of the ancient castle still remains, and it is now used as quarters for the garrison. Towards the north are the apartments in which Mary Queen of Scots was confined after the battle of Langside. The earldom of Carlisle is one of great antiquity, and is held by a branch of the Howard family.

CARLISLE, *Fifth Earl of.* See HOWARD, *Frederick.*

CARLISLE, *Sir Anthony*, an eminent English surgeon, was born at Durham in 1768. He studied under Mr Green, the founder of the hospital in that city, and afterwards in London under the two Hunters, Cruickshank, and Baillie. On the death of Mr Watson he was appointed surgeon to the Westminster Hospital; and was lecturer on anatomy and surgery in the College of Surgeons, of which body he was also elected the president. In 1808 he was appointed professor of anatomy to the Royal Academy, which office he held for sixteen years. He was the author of several detached papers on various professional subjects; in which he showed himself a better observer than a systematic author. To him we are indebted for the introduction of the straight-bladed amputating knife, and the concealed bistoury for such operations as *fistula in ano.* His essay "On the Disorders of Old Age" is his principal work. He died in 1840. (T. S. T.)

CARLOCK, a sort of isinglass imported from Russia. It is made of the sturgeon's bladder, and is used chiefly for clarifying wine.

CARLOS, SAN, a town of South America, in the republic of Venezuela, on the river Aguare, 150 miles S.W. of Caracas. It was formerly a place of considerable importance, but has now probably not more than 5000 inhabitants, principally engaged in the rearing of cattle and in the cultivation of indigo, coffee, and the other productions of the district.

CARLOVINGIAN, pertaining to Charlemagne; as, the *Carlovingian dynasty.*

CARLOW, an inland county of Ireland, in the province of Leinster; situated between 52. 26.—52. 54. N. Lat., and 6. 30.—7. 12., W. Long.; comprising, according to the Ordnance Survey, an area of 346 square miles, or 221,342 acres, of which 184,059 are arable, 31,249 uncultivated; 4927 in plantations; 620 in towns, and 505 under water. Carlow is bounded north by Kildare and Wicklow, east by Wicklow and Wexford, south by Wexford, and west by Queen's County and Kilkenny. Excepting Louth it is the smallest county in Ireland.

Previous to the arrival of Strongbow, and for some time afterwards, what is now the county of Carlow was divided into the districts of Hy Cabanagh and Hy Drone, forming the northern portion of the principality of Hy Kinselagh. Its most ancient Irish families were the Kavanaghs (descended from the celebrated Macmurrough, king of Leinster, who, in the reign of Henry II., for his own preservation, solicited the assistance of the English), the O'Ryans, the O'Nolans, and the O'Mores. After the English settlement, the families of St Aubin, De la Frayne, Bermingham, Carew, De la Landes, Grace and Butler, held extensive possessions here. In the time of Queen Elizabeth appear the families of Bagnal, Eustace, Burton, O'Brien, Ponsonby, Hamilton, Coke, Bernard, Vigors, Burdett, Bunbury, Beresford, Bruen, Bagot, and Browne.

Under the name of Catherlogh, the present county was made shire-ground in the reign of King John, and is now divided into seven baronies: Carlow, Forth, Idrone East and West, Kathvilly and St Mullins Lower and Upper; containing forty-four parishes and parts of parishes. It is within the diocese of Leighlin, of which it forms the greater part. In military arrangement, it is in the Kilkenny district, and contains barracks for cavalry and infantry at Carlow, where the staff of the county militia is also stationed. The headquarters of the constabulary force, consisting of 159

men and officers, are at Carlow; those of the four districts, comprising twenty stations, at Carlow, Bagnalstown, Tullow, and Borris. The assizes are held at Carlow, where the county prison, the county infirmary, and district lunatic asylum are situated. Quarter sessions are held at Carlow, Tullow, and Bagnalstown. There are loan funds at Leighlin Bridge and Tullow, but no savings-bank exists in the county. The only union workhouse is that of Carlow, but portions of the county are within the unions of Shillelagh, Enniscorthy, and New Ross. The amount of property valued under the Act 6th & 7th Will. IV., cap. 84 (Griffith's valuation) is L.164,795, and the net annual value of property rated to the poor is L.166,638. The principal towns are Carlow, pop. in 1851, 9121; Tullow, 2963; and Bagnalstown, 2292. The county returns three members to the imperial parliament, two for the county at large; constituency under 13th & 14th Vict., cap. 69, in 1851, 2090; and one for Carlow borough, constituency 237. Previous to the union with Great Britain, Carlow returned six members to the Irish parliament; two for the county, two for the borough of Carlow, and two for Leighlin borough. According to Ptolemy, the district was inhabited by the *Brigantes* and *Cauci;* Whitaker, however, considers it as forming the possessions of the *Coriundi.* In common with most other parts of Ireland, Carlow was occasionally devastated by the Danes, but not to the same extent as the maritime counties. The relics of antiquity in the county consist of large cromlechs at Browne's Hill near Carlow, and at Tobinstown. A rath near Leighlin Bridge, in which were found several urns of baked earth, contained only small quantities of dust. Some relics of ecclesiastical and monastic buildings exist, and also the remains of several castles built after the English settlement. The ruins of a round tower existed at the commencement of the present century near the church of Kellystown, but are not now visible.

The surface of the county is in general level or gently undulating, and of pleasing appearance, excepting the elevated tract of land known as the ridge of Old Leighlin, forming the commencement of the coal district of Leinster, and the south-eastern portion of the county bordering on Wexford, where the wild and barren granitic range of Mount Leinster and the Blackstairs mountain present a bolder aspect.

There are no lakes or canals in the county, neither does it contain the source of any important river; but on its western side it is intersected from north to south by the "goodly Barrow," which is navigable throughout the whole extent of the county, and affords means of communication with the port of Waterford; and on the eastern border by the Slaney, which passes out of Carlow into Wexford at Newtownbarry, but is not navigable in any part of its course through the county of Carlow. A branch of the Great Southern and Western railway connects the town of Carlow with Dublin, and the Irish South-Eastern line, commencing at Carlow, passes by Bagnalstown to Kilkenny, whence the Kilkenny and Waterford railway completes the means of communication by railway with Waterford.

The soil of the county rests mainly upon the lowest of the three formations of limestone observed in Ireland; but the granite formation of the county of Wicklow is exhibited in the south-eastern border of the county in the Mount Leinster range and the Blackstairs mountain. The great coal district of Leinster commences in the western edge of the county. The sandstone of this formation is frequently of such a nature as to split easily into layers, known in commerce as Carlow flags. Porcelain clay exists in the neighbourhood of Tullow; but no attempt has yet been made to turn this production to use. No metalliferous indications worth mentioning have been observed in any part of the county, and the few chalybeate springs which exist are of no medicinal importance.

The population of the county at the several periods when taken by the census was as follows:—

Year.	No. of souls.	Increase.	Decrease.
1813	69,566	...	...
1821	78,952	9386	...
1831	81,988	3036	...
1841	86,228	4240	...
1851	68,075	...	18,153

The soil of the county is of great natural richness, and generally of a calcareous nature; but although agriculture is the chief occupation of the inhabitants, and the system of tillage not behind what is usually practised in Ireland, much remains to be done in the way of improvement before the capabilities of the soil be fully developed. The extent of land under crops in 1847 was 85,246 acres, and in 1853, 84,422 acres, viz.:—wheat, 6687; oats, 27,707; barley, bere, rye, pease, and beans, 6712; potatoes, 10,608; turnips, 6306; other green crops, 1502; flax, 43; meadow and clover, 24,837. The cultivation of wheat is decreasing, while that of oats, potatoes, and green crops is on the increase. The number of farms in 1847 was 7762, which had declined in 1851 to 5250. The pasture land is of excellent quality, and generally occupied as dairy farms; the butter made in this county maintaining a high reputation in the Dublin market. The farms are frequently large; and great attention is paid to the breeding of cattle. In 1852 the stock of the county consisted of 7291 horses, 2532 mules and asses, 34,581 cattle, 42,825 sheep, 22,618 pigs, 3501 goats, and 106,654 poultry, of the total value of L.366,490.

The staple trade of the county, which has no manufactures, is in corn, flour, meal, butter, and provisions, which are exported in large quantities.

The manners and appearance of the peasantry differ little from those of the agricultural parts of the southern portion of Ireland. The people are, generally speaking, peaceable and industrious, exhibiting few indications of a tendency to agitation or turbulence. They dwell chiefly in detached cottages, or in small villages, there being but three towns, Carlow, Tullow, and Bagnalstown, of which the population exceeds 2000 souls.

In December 1851, there were 59 national schools in operation, attended by 6948 children, 3133 males and 3815 females; and at the same time the following was ascertained to be the state of elementary instruction among the population:—

	Rural Districts.	Civic Districts.	Total.	Per cent. in 1851.	Per cent. in 1841.
Could read and write,.........	7451	2700	10,151	32	27
Could read only, ...	7409	2084	9,493	30	32
Could neither read nor write,	9493	2775	12,268	38	41

The Roman Catholic is the prevailing religion, but what proportion its adherents bear to those of the Established Church is not ascertained. The number of Presbyterians and other Protestant Dissenters is very small.

Carlow, a parliamentary borough, and the capital of the county of Carlow, situated in the heart of the beautiful and well-cultivated vale formed by the river Barrow, which is navigable for small craft to its junction with the Grand Canal at Athy, and affords great facilities for the exportation of grain, butter, &c. to Dublin and Waterford. The population of Carlow in 1841 was 10,400, and in 1851, 9121, inhabiting 1375 houses. It is a neat and in some parts a well-built town, of modern aspect. The principal buildings are—the Roman Catholic College of St Patrick, a plain but spacious building, which, under the superintendence of the late Dr Doyle, rivalled Maynooth as a preparatory seminary for the Roman Catholic priesthood; the parish church, an old building, with a handsome steeple of modern erection; the Roman Catholic chapel or cathedral, a large and elegant structure; the old court-house, and the new court-house where the assizes are held, an octagonal stone

building with a handsome Ionic portico; the lunatic asylum for this and the adjoining counties; the county gaol; the union workhouse; the Wellington bridge over the river Barrow; and a barrack for cavalry and infantry.

This town was formerly of considerable importance. In the reign of Edward III. the king's exchequer was removed hither, and L.500, a large sum at that period, applied towards surrounding the town with a strong wall. The castle (supposed to have been founded by Hugh de Lacy, but sometimes attributed to King John), situated on an eminence overlooking the river Barrow, is still a chief feature of attraction in the general view of the town, but has lost much of its original grandeur in consequence of the blasting operations performed by a physician, who in 1814 attempted unsuccessfully to adapt it for the purposes of a lunatic asylum. It consisted of a hollow quadrangle, with a massive round tower at each angle. In the early part of the reign of Queen Elizabeth it was taken, and the town burned by the Irish chieftain Rory Oge O'More. When summoned to surrender by Cromwell, during the disastrous war of 1641, Carlow submitted without resistance. In the insurrection of 1798, the castle was attacked by an undisciplined body of insurgents, many of whom were intoxicated. They were speedily repulsed, and suffered severe loss, no quarter being given; and, in the confusion of their flight, many of the insurgents took refuge in houses, which the king's troops immediately set on fire. After the slaughter, about 420 bodies were collected and buried.

Carlow obtained a charter of incorporation at an early period, and was re-incorporated, with enlarged privileges, by James I. The corporation, which was styled "The Sovereign, Free Burgesses and Commonalty of the Borough of Catherlagh," and was authorized to return two members to the Irish parliament, was extinguished by the Municipal Reform act. The borough now sends one member to the imperial parliament; constituency in 1853 numbering 208.

Carlow is 49 miles S.W. of Dublin, with which it is connected by a branch of the Great Southern and Western railway. (H. S—R.)

CARLOWITZ, a town of the Austrian dominions, in the Slavonian military frontier and circle of Peterwardein, is situated on the right bank of the Danube eight miles S.E. of Peterwardein. Pop. 5800. It is the seat of the Greek archbishop in the Austrian dominions, and has, besides the cathedral, two Greek churches, a Roman Catholic church, seminaries for the Greek and Catholic clergy, a lyceum, hospital, &c.

CARLSBAD, a town of Bohemia, in the circle of Elbogen, on the Teple, near the junction with the Eger, 70 miles W.N.W. of Prague. It is situated in a narrow valley between steep granite mountains, and consists chiefly of lodging-houses and hotels for the accommodation of visitors, but has also some good shops and private houses, a theatre, hospital, reading-rooms, &c. Carlsbad is the most aristocratic watering-place in Europe. It is most frequented from the middle of June to the middle of August, and the number of visitors averages 5000. The permanent population is only about 3000. The springs differ but little from each other in their component parts, the principal ingredients being sulphate of soda, carbonate of soda, and common salt. The principal springs are the Sprugel, Muhlbrunnen, Neubrunnen, and Theresienbrunnen, having respectively a temperature of 165°, 138°, 147°, and 132° Fahr. They are said to have been discovered during a hunting excursion, by the Emperor Charles IV., to whom a statue has been erected in the market-place. The resident inhabitants make many curious articles in iron, steel, tin, and wood, for which they find a ready market during the season.

CARLSBURG, a fortified town of Transylvania, capital of a county of the same name, situated on the north bank of the Maros, 54 miles south of Clausenburg. It consists of the upper town or citadel, and the lower town. It has a fine Roman Catholic cathedral, containing among other tombs that of John Hunniades; also an ecclesiastical seminary, gymnasium, observatory, public library, mint, &c. Pop. 12,000.

CARLSHAMN, a small seaport-town of Sweden, in the laen of Bleking, on the Baltic, 27 miles west of Carlskrona. It has manufactures of sailcloth, leather, and tobacco. The harbour is small but secure, and by means of it a considerable trade is carried on in corn, iron, timber, pitch, tar, and potash. Pop. 4500.

CARLSKRONA, or Bleking, a laen or province of Sweden, bounded on the north by Wexio, N.E. by Calmar, east and south by the Baltic, and west by Christianstadt. It has an area of 1135 square miles, and (1845) 102,342 inhabitants. Its principal towns are Carlskrona and Carlshamn.

Carlskrona, the capital of the above province, a seaport-town on the Baltic, in N. Lat. 56. 10., E. Long. 15. 33., 55 miles east of Christianstadt. It takes its name from its founder Charles XI., and is built upon five small islands connected with each other and with the mainland by bridges. The town is well built, consisting partly of brick and stone, but principally of wooden houses. The harbour is capacious and secure, with a sufficient depth of water for the largest vessels. It has three entrances; the principal, and the only one practicable for large vessels, is on the south side of the town, and is defended by two strong forts. The dry docks are of great extent, and have been cut out of the solid granite rock. The arsenal and other buildings connected with the docks are extensive, and separated from the town by a wall. The manufactures are, naval equipments, linen cloths, tobacco, and refined sugar; the exports, metals, potash, tar, pitch, &c. The town is very deficient in good water. Carlskrona is the principal station of the Swedish navy. Pop. about 12,000.

CARLSRUHE (*Charles' rest*), a city of western Germany, capital of the Grand Duchy of Baden and of the circle of Middle Rhine. It stands on an elevated plain of the Hardt Forest (which nearly surrounds it), 380 feet above the level of the sea, 5 miles from the Rhine, and 39 miles W.N.W. of Stuttgardt. The Mannheim and Basle railway passes the city. Carlsruhe takes its name from Charles William, Margrave of Baden, who in 1715 erected a hunting seat here, around which the town has since been built. From the palace the principal streets, 17 in number, radiate in the form of an extended fan, in a S.E., S., and S.W. direction. The palace, erected in 1751 on the site of the previous erection of 1715, is a plain building composed of a centre and two wings, presenting nothing remarkable except the tower *Bleythurm*, from the summit of which a splendid view of the city and surrounding country is obtained. In front of the palace is the Great Circle, a semicircular line of buildings, containing the government offices and the palace of the margraves of Baden. Carlsruhe has several fine public squares, the principal of which is the market-place. In the centre of it is a pyramid in honour of Charles William, the founder of the city, whose remains are interred there. Among the public buildings are the council-house, hall of representatives, mint, post-office, barracks, arsenal, theatre, museum, polytechnic school, cannon foundry, a synagogue, and several Protestant and Catholic churches. There are also several hospitals, a deaf-mute asylum, botanic gardens, lyceum; military, medical, and veterinary schools; academies of architecture, painting, and music; and numerous literary and scientific associations. The town is adorned with several public fountains, and is supplied with water by an aqueduct from Durlach. Carlsruhe carries on few manufactures, chiefly silks, cottons, carpets, woollens, jewellery, tobacco, and snuff. Pop. (1849) 23,217.

CARLSTAD, a province or laen of Sweden. It is

bounded W. and N.W. by Norway, N.E. by Falun, E. by Obevo, S. by Wernersborg and Lake Werner. Area 6945 square miles. Pop. (1845) 209,596. The surface is mountainous, interspersed with numerous lakes and rivers, and it has some rich iron mines. The principal towns are Carlstad, Cristenshamn, and Philipstad.

CARLSTAD, the capital of the above province, stands on the island of Tingvalla, at the mouth of the Clara, on the north shore of Lake Werner. It is regularly built, the streets wide and straight, and the houses of wood. It is the seat of a bishop, and has a handsome cathedral, a gymnasium, observatory, theatre, cabinet of natural history, and an agricultural society. The Gotha canal has considerably increased its commerce. Exports copper, iron, corn, salt, timber, &c. Pop. 3400. It was founded by Charles IX., from whom it takes its name.

CARLSTADT, a royal free city of Austrian Croatia, capital of a county of that name, stands on the Kulpa, which here receives the Korana and the Dobra, 32 miles S.W. of Agram. It consists of the fortress, which is surrounded by ramparts, trenches, and palisades; the inner town and suburb. Carlstadt is the seat of a bishop, and has one Greek and five Catholic churches, a Catholic gymnasium, and many handsome public buildings. It has a considerable transit trade, and manufactures the liqueur called *rosoglio*. Pop. 7000.

CARLUKE, a burgh of barony, in the county of Lanark, Scotland, pleasantly situated near the right bank of the Clyde, 5 miles N.W. of Lanark. Pop. (1851) 2845, principally engaged in cotton-spinning, and in the extensive coal, iron, and lime works in the vicinity. There are many fine orchards in the neighbourhood.

CARLYLE, JOSEPH DACRE, a celebrated orientalist, was born in 1759 at Carlisle, where his father was a physician. Having completed his education at the grammar-school, he went to Cambridge, where he took a master's degree, and was elected a fellow of Queen's College. During his stay at college, with the assistance of a native of Baghdad then resident at Cambridge, he had attained great proficiency in Arabic literature; and after succeeding Dr Paley in the chancellorship of Carlisle, he was appointed in 1794 professor of Arabic in the University of Cambridge. Two years before his appointment he published his translation of the *History of Egypt*, written by Maured Allatafet Jemalledin, known in the east as the historiographer of Egypt; and two years after his election to the professorship, a volume of *Specimens of Arabic Poetry*, from the earliest times to the extinction of the khalifs, with some account of the authors. Having been appointed chaplain by Lord Elgin to the Embassy at Constantinople, he prosecuted his researches into Eastern literature, and made a lengthened tour through Asia Minor, Palestine, Greece, and Italy, collecting in his travels several valuable Greek and Syriac MSS., for a projected critical edition of the New Testament, collated with the Syriac and other versions—a work, however, which he did not live to complete. On his return he was presented by the Bishop of Carlisle to the living of Newcastle-upon-Tyne, where he died in 1804. After his death there appeared a volume of poems, descriptive of the scenes of his travels, with prefaces extracted from his journal; and amongst other valuable works which he left unfinished was a half-corrected edition of the Bible in Arabic.

CARMAGNOLA, a town of Piedmont, near the Po, in the province and 16 miles south of the town of Turin. It is well built, and many of its streets and squares are ornamented with porticoes. It has a fine Gothic and several other churches, monasteries, hospital, and a considerable trade in silk, flax, hemp, corn, and cattle. Pop. about 12,000.

CARMAGNOLA, *Francesco Bussone di*, one of the most celebrated Condottieri of the early part of the fourteenth century, was born in Piedmont in 1390. He was captain-general of the Venetian army that several times defeated Visconti, Duke of Milan; but the Venetian state becoming jealous of him, he was recalled, imprisoned, tortured, and then beheaded in 1432, on accusations which are of doubtful character.

CARMEL, a range of hills in Palestine, extending N.W. from the plain of Esdraelon, and ending in a promontory which forms the Bay of Acre. The whole range extends about 18 miles, and its greatest elevation is about 15,000 feet. It is of limestone formation, and received its name from the luxuriant verdure with which it is clothed, especially in spring. In its sides are numerous caverns, to which the prophets used to retreat; but it is principally celebrated for the sacrifice which Elijah offered up there in antagonism to the priests of Baal. On the traditional site of Elijah's altar there appears to have been a temple, which was once the retreat of Pythagoras, and contained an oracle where Vespasian consulted the God of Carmel. The summit is now crowned by a convent belonging to the Carmelites, and in the cave of Elijah lower down is a Moslem sanctuary. There was another Carmel (Josh. xv. 55) near Hebron.

CARMELITES, one of the four orders of mendicant friars, who derive their appellation from Mount Carmel. Their annalists not only attribute the origin of their order to the prophet Elias, but enumerate among their members all the prophets and holy persons mentioned in the Scriptures from Elias to Christ, and likewise include Pythagoras and the ancient Druids. Phocos, a Greek monk, relates that in his time, A.D. 1185, Elias's cave was still extant on the mountain, and near it were the remains of an ancient monastery, at which some years previous a monk of Calabria, by revelation as he pretended from the prophet Elias, had fixed his abode with ten brethren. In 1209 Albert, the patriarch of Jerusalem, gave the solitaries a rigid rule, which was afterwards printed by the Jesuit Papebroch. This was confirmed in 1224 by Pope Honorius III. It contained sixteen articles, by which they were confined to their cells; enjoined to continue day and night in prayer; prohibited from holding property; enjoined fasting from the feast of the holy cross till Easter, except on Sundays, and abstinence at all times from flesh. They were also obliged to labour, and to observe a strict silence from vespers till tierce the next day.

On the peace concluded by the Emperor Frederic II. with the Saracens, the Carmelites were expelled from the Holy Land. Some took refuge in 1238 at Cyprus, and founded a monastery in the forest of Fortania: some of the Sicilian brothers returned to their own country, and founded a monastery at Messina. Several of the English brothers retired to England for the purpose of establishing monasteries: and those of Provence, in 1244, founded one in the desert of Aigualates, about a league from Marseilles. Thus the number of their monasteries rapidly increased, and they held their European general chapter in 1245 at their monastery at Aylesford in England. The order continued to flourish till it had thirty-eight provinces; besides the congregation of Mantua, in which were fifty-four monasteries, under a vicar-general; and the congregations of Barefooted Carmelites in Italy and Spain, which had their peculiar general.

After the establishment of the Carmelites in Europe, their rule was in some respects altered. Innocent IV. added to the first article a precept of chastity, and relaxed the 11th, which enjoins abstinence at all times from flesh, permitting them, when travelling, to eat boiled flesh. This pope likewise gave them leave to eat in a common refectory, and to keep asses or mules. Their rule was again mitigated by Eugenius IV. and Pius II. Hence the order became divided into two branches, viz. *the Carmelites of the ancient observance*, who wore shoes; and those *of the strict observance*, who are the *barefooted Carmelites*—a reform insti-

tuted in 1540 by Sta. Theresa, a nun of the convent of Avila in Castile. These last are divided into two congregations—that of Spain, and that of Italy.

The habit of the Carmelites was at first white, and the cloak was edged at the bottom with several lists; but Honorius IV. changed it for that of Minims. They wear a scapulary, of a brown colour, thrown over the shoulders.

CARMENTALIA, an ancient Roman festival, celebrated annually on the 11th and 15th of January in honour of Carmenta or Carmentis, a prophetess of Arcadia, and the mother of Evander, with whom she came into Italy sixty years before the Trojan war. This feast, which was chiefly celebrated by women, was established in commemoration of a great fecundity among the Roman matrons after a general reconciliation with their husbands, with whom they had been at variance on account of the use of coaches having been prohibited them by an edict of the senate.

CARMICHAEL, ARCHIBALD NISBET, an accomplished Greek scholar, born at Edinburgh, Sept. 26, 1794. He was elected in 1824 to one of the classical masterships in the Edinburgh Academy; and in this situation he died Jan. 8th, 1847. He published several classical text-books, but is best known by his able treatise on *Greek Verbs, their leading Formations, Defects, and Irregularities.*

CARMINATIVE (Latin *carmen*, a verse or charm), a term applied to medicines which relieve flatulencies by exciting gentle perspiration. Among the ancients their operation was accompanied by the singing of a stanza (*carmen*) —whence the term.

CARMINE, a very brilliant red colour, obtained by the aid of ammonia from the cochineal insect, *Coccus cacti.* For an excellent method of preparing this pigment, see Berzelius, *Traité de Chimie*, tom. vii. p. 676.

CARMONA, a town of Spain, province of Seville, situated on a gentle elevation overlooking a plain, one of the richest in Spain, being almost wholly covered for more than twenty miles with woods of olive trees. A castle, now in ruins, was formerly the principal fortress of Peter the Cruel, and contained a spacious palace within its defences. The principal entrance to the town is by an old Moorish archway; and part of the ancient college of San Teodomir is of Moorish architecture. The gate on the road to Cordova is partly of Roman construction; and the tower of the church of San Pedro is an imitation of the Giralda at Seville. The manufactures consist of woollen stuffs, hats, soap, glue, leather, &c.; but its principal trade is in corn and cattle. It was the Roman Carmo, a strongly fortified city; and its strength was greatly increased by the Moors, who surrounded it with a strong wall, now in ruins, and ornamented it with fountains and magnificent palaces. Pop. 15,121.

CARNAC, a village of France, department of Morbihan, in the arrondissement and 18 miles S.E. of L'Orient. About three-fourths of a mile from the village is the great Celtic monument of Carnac, consisting of 11 lines of rude granitic blocks set on end, forming 10 avenues with a curved row of 18 stones touching at its extremities the two outside rows. There are said to be several thousands of these stones, none exceeding 18 feet in height; and a very large proportion are cubical masses not more than 3 feet high. The object and the epoch of the construction of this extraordinary monument are alike unknown.

CARNAC, *Temple of.* See THEBES.

CARNATIC, a large province of Southern India, so denominated by Europeans. It extends along the eastern coast about 600 miles in length, and from 50 to 100 miles in breadth. It is bounded on the north by the Guntoor circar, the limit being the small river Gundezama, which falls into the sea at Muntapilly, and thence it stretches southward to Cape Comorin. It is divided into the Southern, Central, and Northern Carnatic. The region south of the river Coleroon, which passes the town of Trichinopoly, is called the Southern Carnatic. The principal towns of this division are Tanjore, Trichinopoly, Madura, Tranquebar, Negapatam, and Tinevelly. The Central Carnatic extends from the Coleroon river on the south to the river Pennar on the north: its chief towns are Madras, Pondicherry, Arcot, Vellore, Cuddalore, Pullicat, Nelloor, &c. The Northern Carnatic extends from the river Pennar to the northern limit of the country; and the chief towns are Ongole, Carwaree, and Samgaum. The soil is various: in a great part of the country it is deep and rich, whilst in other tracts it is sandy, and, as water is scarce, unproductive. This defect is, however, supplied by artificial means; an extensive system of canal irrigation having been established within the delta formed by the Coleroon and the Cauvery. In such parts as are at too great a distance to have water thus conveyed to them, tanks are constructed, some of them of great extent, and formed by inclosing the waters deposited in low situations with a strong mound of earth; while others are of a smaller size, and of a quadrangular form, lined with stone, and with a flight of steps descending to the bottom. In these reservoirs are collected supplies during the periodical rains, which are afterwards distributed over the rice fields, or reserved for the use of the cattle in the dry season. The climate, except on the sea-coast, where there are sea and land breezes, is liable to excessive heats, the thermometer standing in the coolest and shadiest parts at 115 degrees. Occasional showers fall in May, June, and July; but the S.W. monsoon which prevails during those months expends its violence chiefly on the opposite coast of Malabar. As the S.W. monsoon dies away, the N.E. sets in, and continues to blow during October and November, bringing with it an annual rainfall of about 30 inches. The principal rivers are the Kistnah on the northern frontier, the Cauvery and Coleroon, the Pennar and the Palar; all of which rise in the high lands among the Ghauts, and take an easterly course to the Bay of Bengal. The vegetable productions are numerous, and similar to those found in most other parts of Hindustan. Famines and scarcities, owing to drought, have been more frequent in the Carnatic than in the Bengal provinces. This country in former times was the scene of unintermitting violence and strife between the numerous chieftains and petty potentates among whom it was divided; and forts and fortresses accordingly crown almost all the elevated points. They are built of a square form; but from the long period of internal tranquillity which the country has enjoyed, are now rapidly falling into decay. Large temples and other public monuments of civilization abound in the Carnatic. The temples are commonly built in the middle of a square area, and inclosed by a wall fifteen or twenty feet high, which conceals them from the public view, as they are never raised above it. The Carnatic, as above defined, comprehends within its limits the maritime provinces of Nellore, Chingleput, South Arcot, Tanjore, Madura, and Tinevelly, besides the inland districts of North Arcot and Trichinopoly. The aggregate population has been returned at 10,142,319, which consists chiefly of Hindus of the Brahminical persuasion, the Mohammedans being but thinly scattered over the country. The Brahmins rent a great proportion of the land; and also fill different offices in the collection of the revenue and the administration of justice. Throughout the country they appropriate to themselves a particular quarter in every town, generally the strongest part of it.

Trade and manufactures are carried on to a considerable extent. The exports are piece goods, consisting mostly of blue cloths, coarse chintzes, and the like; also indigo, grain, and other commodities.

The Carnatic was first invaded by the Mohammedans in A.D. 1310, when they defeated the Hindu sovereign and conquered the country. After this period it was liable to

an occasional tribute to the Deccany sovereigns; and early in the eighteenth century it was overrun by the armies of Aurungzebe. It was dismembered from the Mogul empire in 1717, when Nizam ul Mulk obtained possession of the Deccan and the south of India. In 1743 he appointed Anwar ud Deen nabob of the Carnatic and Arcot; in 1754 a competition for the government arose; and after a long and tedious war, in which the English and the French took different sides, Mohammed Ali was left in possession of that portion of the Carnatic which was the fruit of the successes achieved by the British. The Carnatic was laid completely waste in its central parts by Hyder Ali, but was again reconquered by the British in 1783. In 1801 all the possessions of the nabob of the Carnatic were transferred to the British by treaty, the conditions of which were, that a revenue should be reserved to the nabob of several lacs of pagodas annually; and that the British should undertake to support a sufficient civil and military force for the protection of the country and the collection of the revenue. A liberal establishment was also provided for the other branches of the family of Mohammed Ali Khan.

The Southern Carnatic, when it came into the possession of the British, was occupied by military chieftains called polygars, who ruled over the country, and held lands by doubtful tenures. They were unquestionably a disorderly race; and the country, by their incessant feuds and plunderings, was one continued scene of strife and violence. They were transferred to the dominions of the British in the year 1792, in virtue of a treaty concluded by Lord Cornwallis with the nabob of Arcot. But the conditions of that treaty were variously understood; and it was found necessary, for the peace of the country, to reduce these refractory polygars to obedience. In 1801 an insurrection took place, which was crushed by a military force; after which their forts and military establishments were abolished, the country was searched for arms, and some severe examples being made, tranquillity was restored. (D. B—N.) (E. T.)

CARNATION (from *caro carnis*, flesh), in painting, denotes those parts of a picture that represent flesh, or which are naked and without drapery. Titian, Correggio, Rubens, and Vandyk, excelled in carnations.

Carnation is also the name given by gardeners to a cultivated species of Dianthus.

CARNAUL. See KURNOOL.

CARNEADES, a celebrated philosopher, and the founder of the Third or New Academy at Athens, was born at Cyrene in Africa, about B.C. 213. He was a strenuous opponent of the Stoics, and applied himself with great zeal to refute the works of Chrysippus, one of the most eminent philosophers of their sect. In B.C. 155 Carneades, accompanied by Diogenes and Critolaus, was sent on an embassy to Rome, to deprecate a fine of 500 talents which had been imposed on the Athenians for plundering the city of Oropus. Before obtaining an audience of the senate, these philosophers harangued the people in various parts of the city, and drew together great multitudes by their eloquence. The Athenian ambassadors, said many of the senators, "were sent rather to force us to comply with their demands, than to solicit them by persuasion;" meaning that it was impossible to resist the powerful eloquence of Carneades. His subtilty in argument was most conspicuously displayed in his two orations on justice. The first of these was in commendation of the virtue; and the second, which he delivered on the following day, was a refutation of the first, and showed that justice was but a mere matter of compact for the maintenance of civil society. This grieved the honest mind of Cato, who urged the senate to send Carneades back to Athens lest the Roman youth should be corrupted by his pernicious doctrines. Such indeed, according to Plutarch, was the enthusiasm excited by his discourses, that the young Romans were carried away with a kind of mania for philosophizing, and forsook their usual pursuits. Paradox was the element of Carneades: he delighted in demolishing his own work, because it served in the end to confirm his grand principle—that there are only probabilities or resemblances of truth in the mind of man; so that of two things directly opposite, either may be chosen indifferently. Quintilian remarks, that although Carneades might argue in favour of injustice, yet he was invariably actuated by the strictest sense of honour. He died in B.C. 129, at the age of 85. (See *Diog. Laert.* iv.)

CARNEDD, in *British Antiquity*, denotes a cairn or heap of stones, thrown together on occasion of confirming and commemorating a covenant. (See Gen. xxxi. 46.) They were also used as sepulchral monuments.

CARNEIA, in *Antiquity*, a festival in favour of Apollo surnamed Carneios, and celebrated in most of the cities of Greece, but especially at Sparta, where it was instituted. The reason of the name, as well as the origin of the institution, is controverted. It commenced on the seventh day of the month Carneios, and lasted nine days. The ceremonies were an imitation of the method of living and discipline used in camps.

CARNELIAN, a well-known variety of calcedony, the produce of India. See CALCEDONY, and AGATE.

CARNIFEX, among the Romans, the common executioner. By reason of the disgrace attached to his office, the carnifex was prohibited by law from residing within the city. In writers of the middle ages carnifex signifies a butcher.

CARNIOLA. See AUSTRIA.

CARNIVAL, a season of festivity, observed with much pomp and solemnity in the chief cities of the Catholic countries of Europe. It begins on the day of the Epiphany, and ends on Ash-Wednesday. The etymology of the word, like the origin of the fête itself, is uncertain. The most probable is that which derives it from the Latin words *carni vale*—farewell to flesh—inasmuch as a provision is in this particular made beforehand against the abstinence observed by all good Catholics during the season of Lent. From the earliest ages it has been celebrated in all Catholic countries with much pomp and show, more especially at Venice and Rome. The most widely diffused recreation is that of masquerades, which, though they have now declined considerably both in frequency and splendour, are still much in vogue in France and Italy, as well as in southern Germany. Great license, often degenerating into licentiousness, prevailed, and still continues to prevail in these countries during that season of the year.

CARNIVOROUS, an epithet applied to those animals which naturally seek and feed on flesh.

It has been disputed whether man is naturally carnivorous. Those who take the negative side of the question insist chiefly on the structure of our teeth, which are mostly incisores or molares; not such as carnivorous animals are furnished with, and which are proper to tear flesh in pieces; and to this it may be added, that, even when we do feed on flesh, it is not without a preparatory alteration by boiling, roasting, or the like. To these arguments Dr Wallis subjoins another, which is, that all quadrupeds which feed on herbs or plants have a long colon, with a cæcum or some equivalent at its upper end, which conveys the food by a long progress from the stomach downwards, in order to its slower passage and longer stay in the intestines; but that, in carnivorous animals, such cæcum is wanting, and instead of it there is a shorter and more slender gut, and a quicker passage through the intestines. Now, in man the cæcum is very visible; a strong presumption that nature did not intend him for a carnivorous animal. It is true the cæcum is but small in adults, and seems of little or no use; but in a fœtus it is much larger in proportion; and it is probable that our customary change of diet, as we grow up, may occasion this shrinking. But to these arguments Dr Tyson

replies, that if man had been designed by nature to be not carnivorous, there would doubtless have been found, somewhere on the globe, people who do not feed on flesh, which is not the case. Neither are carnivorous animals always without a colon and cæcum; nor are all animals carnivorous which have these parts. The opossum, for instance, has both a colon and cæcum, and yet feeds on poultry and other flesh; whereas the hedgehog, which has neither colon nor cæcum, and so ought to be only carnivorous, feeds on both. Hogs, too, which have both, will sometimes feed on flesh; and rats and mice, which have large cæcums, relish bacon as well as bread and cheese. Lastly, the human race are furnished with teeth necessary for the preparation of all kinds of food; from which it would seem that nature intended we should live on all. And as the alimentary duct in the human body is fitted for digesting all kinds of food, we may conclude that nature did not intend to deny us any.

CARNOT, Lazare Nicolas Marguerite, one of the most consistent but intemperate of the French republicans, of the bloody period of the first French revolution, was born at Nolay in Burgundy, May 13, 1758. After a good mathematical education in his native province he was admitted as an officer of the engineer corps under the patronage of the prince of Condé, and was a captain in that corps when the storms of the revolution thrust him forward in political life, as he was beginning to be known by some mathematical essays and poetic effusions of small merit. In 1791 he was returned a member of the National Assembly for the Pas de Calais, and was soon engaged in the most violent measures of the republican party. It would have been lucky for his memory had his zeal been less unscrupulous; but he soon leagued himself with the party of the Mountain, became a member of the committee of public safety under Robespierre, voted for arming with pikes 30,000 *sans culottes*, for the condemnation of the princes, and the execution of the king; in short, he was highly accountable for the indiscriminate bloodshed that characterized the Reign of Terror. His genius, however, was more military than political, and he laboured energetically in improving the discipline of the French army; is said to have been the proposer of the military conscription; cashiered on the field a general who had retreated before the enemy; and as commissary of the republic put himself at the head of the troops. It is certain that his activity and spirit produced great effects on the soldiery, and thus he contributed materially to the wonderful successes of the armies of France. In 1794 he was president of the convention; but in the following year his severities had rendered him unpopular; and when Legendre moved his arrest in the convention, he was saved by the exclamation of a member, "This is the man who organized victory in the French armies." Afterwards Carnot became one of the five directors of the republic, and was the author of the *Plan for the Invasion of England*, by landing two armies simultaneously on the coasts of Sussex and Yorkshire. In this tract he stated that walls and hedges, instead of being a defence, would aid the advance of a disciplined enemy; and maintained that open plains would give us greater advantages, by permitting the superiority of our cavalry and horse artillery to have full effect; while he greatly underrated the efforts of an irregular force, animated by a love of home, and of national independence. Soon afterwards Carnot was proscribed, and compelled to take refuge in Germany, where, though under the protection of a monarch, he published his *Mémoire Justificatif*, in which he declares himself the "irreconcilable enemy of kings." This memoir hastened the fall of the Directory, already shaken by its vices and its crimes. On its downfall he returned to France, and he was minister of war in 1800, but soon resigned his office; having, with a consistency then not common, opposed the consulship for life; and afterwards the imperial title to Bonaparte, when, as one of the tribunate, he persisted in refusing to affix his name to the registers.

Carnot now devoted himself to the peaceful pursuits of science. He was an active member of the Institute. His best production in this field, perhaps, is the *Réflexions sur la Métaphysique du Calcul Infinitésimal;* next to that we would place his *Principes Fondamentaux d'Equilibre et Mouvement*—works of great originality and power. His work *De la Défense des Places Fortes* is far less esteemed by competent judges. From the Institute he was twice expelled; first, through the influence of the Directory, and secondly, on the restoration of the Bourbons in 1814. On Napoleon's reverses in the Russian campaign, he offered his services to his country, and was made governor of Antwerp, which he defended till the abdication in 1814, when he retired to Germany. On Napoleon's return from Elba, he was minister of war; but on the overthrow of the emperor of the French, Carnot retired first to Warsaw, and finally to Magdeburg, where he died in 1823.

The republican principles of Carnot, and the stern severity of his temper, impressed the lines of his countenance, and indicated the cruelty of which he has too justly been accused; but he did not disgrace himself by the peculation of which his brother directors of the republic cannot be acquitted. (T. S. T.)

CARNUNTUM, an ancient Celtic town, afterwards a Roman colony or municipium in Pannonia, on the Danube. It was for three years the residence of Marcus Aurelius, during his wars with the Marcomanni and Quadi. It was taken and destroyed by German invaders in the fourth century, but was afterwards rebuilt. It was finally destroyed in the wars against the Magyars in the middle ages. Extensive ruins of this town are to be seen not far from Presburg.

CARO, Annibale, a celebrated Italian poet, born at Civita Nuova in 1507. He held successively the office of confidential secretary to the dukes of Parma, Pier-Lugio, and Ottavio Farnese, and to the cardinals Rameccio and Alexander. His works consist principally of Italian translations from the Greek of Gregory Nazianzen, Cyprian, and Aristotle, and from the Latin of Virgil. They are uniformly remarkable for the purity and elegance of their style. His fame has been greatly damaged by the virulence with which he attacked Ludovico Castelvetro in one of his canzoni, and his baseness in denouncing him to the holy office for having translated some of Melancthon's writings. He died at Rome about 1566.

CAROLAN, Turlogh (1670–1738), an eccentric musical genius, born at Nabber, in Westmeath, where his father was a poor farmer. Having lost the use of his eyes when a child, he resorted to playing on the harp, by which he maintained himself. (See Kitto's "*Lost Senses.*")

CAROLINA, North, one of the United States of North America, bounded N. by Virginia, W. by Tennessee, S. by Georgia and South Carolina, and E. by the Atlantic Ocean. It lies between 33. 50. and 36. 30. N. Lat., and 75. 25. and 84. 30. W. Long. Length 430, breadth 198 miles; area, 43,800 square miles, or 2,803,200 acres.

The entire coast is lined with low narrow belts of sand, broken through at intervals by channels, communicating between the ocean and the lakes or lagoons which lie between the sand-banks and the mainland. South of Cape Lookout, these inlets are numerous and the lagoons narrower; while north of that cape the converse is the case. Beyond these banks are extensive shoals; furious gales, too, are prevalent; so that, altogether, the navigation of this coast is highly dangerous. Ocracoke Inlet, the only navigable passage north of Cape Lookout, is full of shifting sand-banks, and at low tides even in the main channel has only six feet of water. Roanoke Inlet, opposite the island of that

name, is now obstructed; but operations have been commenced for re-opening it. To the northward, between the main land and the narrow beach stretching southward from Cape Henry, lies Currituck Sound, 50 miles in length by from two to ten in breadth. West of this, running inland, is Albemarle Sound, 60 miles in length from east to west, and from 5 to 15 in breadth. Its waters are fresh, and not subject to tidal influences, though they are affected by particular winds. These two sounds communicate with the Sound of Pamlico, which lies south of Currituck, and is 86 miles long by from 10 to 20 in breadth; its general depth is about 20 feet, but it abounds in shoals; it is somewhat influenced by the tides, and is connected with the ocean by Ocracoke Inlet. Cape Hatteras, the headland of the triangular island which separates Pamlico from the ocean, is one of the most dangerous projections on the American coast. Cape Fear and Cape Lookout are also, as their names indicate, dangerous points on this coast. The islands are barren, and only inhabited by a few fishermen and pilots.

From the coast, for 60 or 80 miles inland, the land is low, traversed by sluggish and muddy streams, and abounds in extensive marshes and swamps, which cover about one-tenth of the whole state. The soil, except along the banks of the streams, where it is often fertile, is sandy and barren. The natural production of this soil is the pitch pine, which attains a fuller development here than in the states further north, and yields vast quantities of tar, pitch, turpentine, and lumber. The swamps are usually overgrown with cedars and cypresses, intermingled with maples, poplars, and white oaks, and having an almost impervious under-growth of reeds, grasses, briers, &c. Some of these swamps have been drained, and produce good crops of rice and cotton.

Beyond this region the country begins to rise into small hills; stones appear and ripple the surface of the streams. For 40 miles beyond the flat region, as far as the lower fall of the rivers, extends a flat belt of land, moderately undulating, with a sandy soil, of which pitch pine is the principal natural production. West of the falls, the surface is more undulated, the streams flow more swiftly, and the land is more fertile, producing wheat, rye, barley, oats, flax. Farther west, beyond the Yadkin and the Catawba, is an elevated region forming part of the great table-land of the United States, and lying from 1000 to 1200 feet above the level of the sea. Towering above it are the peaks of the Blue Ridge, the chief of which are the Black Mountain, with an elevation of 6426 feet, the highest east of the Rocky Mountains; and Roan Mountain, the summit of which is a broad meadow, with an elevation of 6038 feet above the sea. Mount Ararat, or the Pilot Mountain, in Surrey county, situated in a comparatively level region, exhibits a striking symmetry of form, being nearly cylindrical, and from the summit, which is accessible by a path in some places nearly perpendicular, the view is grand and extensive. Between the mountain ranges in the western part of the state the soil is productive.

North Carolina is well watered by numerous streams, many of them very considerable, but offering few facilities for navigation. They are generally shallow near their mouths, or lost in lagoons, or broken by falls in the upper part of their courses. Cape Fear river is the principal one whose course lies entirely within the state, and is, moreover, the only large stream that flows directly into the ocean; its principal sources are the Haw and the Deep, which rise near the northern boundary of the state, and unite their waters at Haywood, in Chatham county; it flows in a S.E. direction, and has a course of about 280 miles. At Fayetteville it is navigable for large boats, and above Wilmington it forms two branches which re-unite below that town, flowing to the ocean in a broad, sluggish stream, obstructed by sand-banks, and difficult of navigation. By diminishing the breadth of the river, and by stopping up some of the smaller outlets, these defects have in some measure been removed, and the main channel, as far as Wilmington, has a depth of from 12 to 13 feet. The S.W. or main entrance has a depth of from 10 to 14½ feet on the bar. The Chowan and Roanoke flow into Albemarle Sound; the former, formed by the union of the Meherrin and Nottaway, is accessible for small vessels to Murfreeboro'; the latter is navigable for 30 miles for the small craft which ply on the sound. The Tar, which flows into the Pamlico Sound, is navigable for vessels drawing 8 feet of water to Washington; and the Neuse, also flowing into the Pamlico Sound, for large boats to Kingston. The Waccamaw, Lumber, Yadkin, and Catawba, pass into South Carolina. From the west of the Blue Ridge flow New River, Wataga, French Broad, Little Tennessee, and Hiwassee, the waters of which flow into the Ohio.

Professor Olmsted, in his report on the geology of North Carolina, has given a full and accurate account of its mineral resources, which are extensive and valuable. The low country consists of deposits of sand and clay, similar to, and belonging to the same age (the tertiary) as those of Eastern Virginia and Maryland. These beds contain few minerals, but abound in deposits of shell, marl, fossiliferous limestone, green vitriol, and bog-iron ore. A ledge of micaceous rocks, seen in the ravines and beds of rivers, forms the line which divides the low land from the upper country. Formations of mica slate, chlorite slate, gneiss, and granite, lie west of this line. Among the minerals of this section are hematitic iron ores, plumbago, and occasionally soapstone and serpentine. This strip is succeeded by a belt of sandstone, running south-westerly from Granville across the state. Freestone of different qualities is abundant in some parts of the formation, which also contains argillaceous iron ore, and some coal measures of great extent, including the best varieties of bituminous and anthracite coal. Next to this is the great slate formation, about 20 miles in breadth, running from N.E. to S.W., quite across the state. Within this district are found numerous beds of porphyry, soapstone, serpentine, greenstone, and very fine whetstone-slate. The slate formation is succeeded by another belt of primary rocks, reaching nearly to the Blue Ridge. This comprises the gold region of North Carolina. Iron ore is also abundant, chiefly in the form of magnetic oxide, and has been extensively wrought. The gold district is for the most part barren, and the inhabitants poor and ignorant. The principal mines are Anson's, Read's, and Parker's. The first is in Anson county, and was once productive; but operations have been retarded by a dispute as to the ownership of the land. Read's mine is in Cabarrass county, and was the first wrought. Large masses of metal, weighing 400, 500, or 600 pennyweights are occasionally met with, and one piece was found weighing 28 lb. avoirdupois. Parker's mine is situated on a small stream 4 miles south of the Yadkin. The metal exists chiefly in flakes and grains; but a mass weighing 4 lb. 11 oz. has been found.

No state in the Union possesses a greater variety of staple productions. All kinds of grain growing in the north are successfully cultivated. The striking diversity of climate and soil between the low lands of the east, the high lands of the west, and the moderately diversified interior, produces a corresponding diversity in its agricultural productions. The low lands yield cotton, rice, and indigo; and grapes, plums, &c. grow spontaneously. Further west, in the interior and valleys of the high lands, the soil is well adapted for wheat, tobacco, hemp, Indian corn, and the grains and fruits which flourish northward. The mountainous districts afford excellent pasturage for herds of cattle and horses.

By the census of 1850, the improved farm lands amounted to 5,453,975 acres, and 15,543,008 acres of unimproved land attached to the farms. The principal productions are wheat, rye, Indian corn, oats, rice, tobacco, cotton, pease, beans, potatoes, barley, buck-wheat, hay, hemp, flax, hops, &c. The value of home-made manufactures during the above year was $2,086,522. During the last few years several cotton and woollen manufactories have been established.

The progress of the population from 1790 to 1850 was as follows:—

	Whites.	Free Coloured.	Slaves.	Total.
1790	288,204	4975	100,572	393,751
1800	337,764	7043	133,296	478,103
1810	376,410	10,266	168,824	555,500
1820	419,200	14,612	205,017	638,829
1830	472,843	19,543	245,601	737,987
1840	484,870	22,732	245,817	753,419
1850 { Males	273,025	13,298	144,581	869,039
Females	280,003	14,165	143,967	

The number of males engaged in professions, trades, and other occupations in 1850 was 139,387; of these, 81,898 were farmers and 28,143 labourers. The births for the year ending 1st June 1850 were 16,648 whites and free coloured, and 8086 slaves; deaths, 6028 of the former and 4329 of the latter.

The militia is composed of 79,448 men, of whom 4267 are commissioned officers. Every white male citizen between the ages of 18 and 45 years, unless exempt by law, is liable to military duty. The revenue from all sources for the year ending 31st October 1852 was $366,728; the expenditure, $249,254.

The value of exports for year ending June 1851, was $431,095; imports $206,931. The total shipping owned in the state at 30th June 1850, was 45,218 tons, of which 14,932 tons were registered, 27,535 were enrolled and licensed, and 2751 licensed (under 20 tons). The enrolled and licensed shipping are all employed in the coasting trade, and of this 3226 tons were navigated by steam. The principal ports are Wilmington and Newbern. At 1st January 1853, 249 miles of railway were in operation.

The state in 1850 had 2657 public schools, with 2730 teachers, and 104,095 pupils; 272 academies and other schools, with 403 teachers and 7822 pupils; and 5 colleges with 29 teachers and 513 pupils. The number returned by families as attending school during the year was 100,591 whites and 217 free coloured; in the former case being equal to 5½ of the white population. Adults who could not read and write, 26,239 male, and 47,327 female whites, and 6857 free coloured. There were 4 public schools, 19 Sunday school, 5 college. and 9 church libraries, with 29,592 volumes, in the state. The total number of churches in the state was 1795, with 572,924 sittings. Of these churches 615 were Baptist, 784 Methodist, 151 Presbyterian, 50 Episcopal, 49 Lutheran, 54 Free, and 4 Roman Catholic.

The legislative body consists of a senate and house of representatives; the former composed of 50, and the latter of 120 members. The right of suffrage is vested in every free white man 21 years of age who has resided in the district for 12 months, and owned a freehold within the same for 6 months; but the freehold qualification is not required in voting for representatives. The senators and representatives are chosen biennially. The governor is elected for two years, by the persons qualified to elect members of the house. The supreme court consists of a chief justice and 2 associate justices, and holds three sessions annually, 2 in the city of Raleigh, and 1 in Morgantown. The superior or circuit courts, of which there are 7, consist of a judge and solicitor, who hold courts twice a-year in each county of the state. North Carolina sends 8 representatives to the American congress.

The first English settlement in North America was made on Roanoke island in the state. Queen Elizabeth in 1584 granted by patent to Sir Walter Raleigh such lands as he might discover in America "not possessed by any Christian people." He accordingly despatched two vessels, which anchored early in July in Ocracoke Inlet; and the accounts brought home were so favourable that Sir Walter at once sent out a colony. Discouraged, however, by their contests, and the scarcity of provisions, they returned home. A few days after their departure, a ship under Sir Richard Grenville arrived; and finding the colony gone, left 15 men with provisions for 2 years to keep up the settlement. Raleigh then sent out another colony, which landed on Roanoke in July 1587, but found no traces of Grenville's men except a few scattered human bones. About 100 persons were left at the settlement; but on account of the troubles consequent on the attempted Spanish invasion of England, Roanoke was not revisited till 1590, when none of the colonists were found. The first permanent settlement was made in 1650 by some whites from Virginia; and in 1667 the colony obtained a representative government. In 1717 it was brought under the direct control of the crown; and in 1720 was divided into North and South Carolina.

Carolina, *South*, one of the United States of North America, is situated between N. Lat. 32. 4. and 35. 12., and W. Long. 78. 25. and 83. 19. It is of an irregularly triangular form, and is bounded N. by North Carolina, S.E. by the ocean, and S.W. by Georgia, from which it is separated by the river Savannah. Area 28,000 square miles. Its coast is upwards of 200 miles in length, and is lined towards the south by a chain of fine islands, between which and the shore the navigation is convenient. The land is naturally divided into an upper, middle, and lower country. The lower country extends for about 100 miles from the coast, and is covered with pine forests, interspersed by swamps and marshes, and permeated by sluggish streams The middle country is an undulating district chiefly of sand, which extends about 50 or 60 miles westward. This tract occasionally presents an oasis of verdure or a field of maize, but otherwise offers little to attract the agriculturist. Westward of this is the "Ridge," where the country rises suddenly and somewhat precipitously, and afterwards continues gradually to ascend. Its surface is beautifully diversified with hills and dales, interspersed with extensive forests, and watered by fine streams. This part of the country gradually ascends to the mountainous region in the west, where the Blue Ridge passes through the state. One of the most conspicuous of the peaks here is the Table Mountain, which rises to the height of 4000 feet above the sea.

South Carolina is abundantly watered. One of its triangular sides is washed by the ocean, and another is watered by the river Savannah, accessible to vessels for more than half its length, and to small boats for 100 miles farther. Its principal rivers have their sources in the Blue Ridge. The great Pedee, 450 miles long, rises in North Carolina, where it has the name of Yadkin; and, after receiving the waters of Lynch's Creek and Black River from the right, and Little Pedee and Waccamaw from the left, it falls into Winyaw Bay. It is navigable for sloops for 130 miles. The Santee is formed by the junction of the Catawba and the Congaree. Steamboats ascend to Camden and Columbia; and by the aid of canals there is navigation for boats to the mountains. The Congaree is itself formed by the junction of two considerable navigable streams, the Saluda and Broad rivers. The Edisto, Cambahee, Ashley, Cooper, and Coosawatchie, are smaller streams in the southern part of the state, navigable for some distance by small vessels. The lower part of the courses of these rivers are generally shallow, and obstructed by bars. The coast presents no good harbour, but has numerous entrances, accessible to small vessels, and very advantageous to an extensive and active coasting trade. The harbour of Charleston, the largest and most commercial place in the state, is obstructed at its entrance by a dangerous sand-bar; and that of Georgetown—at the head of Winyaw Bay, 13 miles from the ocean—will admit only small vessels. The harbour of Beaufort, on the island of Port Royal, is the best in the state, but little frequented. St Helena Sound is the most spacious opening for a great distance along the coast; but, although about 3 miles wide and 10 miles long, it is too much beset by shoals to be of any great commercial value. The range of islands on the southern coast are separated from the mainland by narrow channels. These islands are low and flat, covered with forests of live oak, pine, and palmettoes, and yield the black seed or Sea Island cotton. Formerly these were the haunts of alligators, but they are now well peopled and cultivated.

Its geological character much resembles that of North Carolina. The western part of the state belongs to the auriferous belt of the Atlantic slope, and for a number of years the production of gold has been such as to induce the miner to continue his pursuit. The washings are the most productive; but in several cases large nuggets have been dug up. Iron of a very superior quality is abundant, but coal is not found. Granite, sienite, gneiss, mica slate, soapstone, porcelain-clay, limestone, chalk, red and yellow ochre, and precious stones, are found in various parts of the state.

A great similarity of surface and soil is observable in the

Carolina.

upper regions; and this is also true of the lower districts. Oak is the natural growth of the one, and pine of the other. Clay forms the soil of by far the largest portion of the state, and except in the immediate vicinity of the ocean is almost the universal substratum. The high lands above the falls of the rivers are naturally much superior to those of the pine-covered region; but the alluvial bottoms of the former are greatly surpassed in richness by the river swamps of the latter. The swamps, covering about 2000 square miles, are capable of thorough and economical draining, and may thus be converted into tracts of great fertility. The pine forests cover about 6,000,000 acres.

South Carolina is remarkable for the richness, variety, and abundance of its productions. Of articles of food it produces rice, wheat, Indian corn, oats, rye, barley, peas, beans, potatoes, &c., besides cotton, hemp, flax, indigo, tobacco, sugar-cane, olives, oranges and other fruits, and a variety of culinary and medicinal plants. Its woods abound in game, and the shores and rivers present almost every variety of fish.

The manufactures are chiefly such as are required in an agricultural country. The number of manufacturing establishments in operation in June 1850, and producing to the value of $500 and upwards annually, was 1473. Of these 18 were cotton factories, 91 tanneries, and 6 iron works. The value of exports for the year ending 3d June 1852, was $11,670,021, the whole being the produce of the state; imports $2,177,614. The number of ships which entered during the year ending 30th June 1850 was 305 vessels of 96,916 tons; the number that cleared was 375 vessels of 125,052 tons. The total amount of shipping owned in the state was 36,072 tons, of which 17,126 tons were registered, 18,926 enrolled and licensed, and 69 licensed (under 20 tons). Of the registered tonnage 1116, and of the enrolled and licensed 6339 were propelled by steam. South Carolina is said to have 2400 miles of inland navigation; and in 1852 had 447 miles of railway in operation, 203 in progress, and 98 projected.

The decennial population since 1790 was as follows:—

		Whites.	Free coloured.	Slaves.	Total.
1790		140,178	1801	107,094	249,073
1800		196,255	3185	146,151	345,591
1810		214,196	4554	196,365	415,115
1820		237,440	6826	258,475	502,741
1830		257,863	7921	315,401	581,185
1840		259,084	8276	327,038	594,398
1850	Males,	137,747	4131	187,756	668,507
	Females,	136,816	4829	197,228	

The births during the year ending 1st June 1850, and surviving at that date, were, of whites and free coloured 6607, and of slaves 9194; deaths—2879 of the former, and 5167 of the latter.

The number of public schools in the state in 1850 was 724, with 739 teachers, and 17,838 pupils; of academies and other schools, 202, with 333 teachers, and 7467 pupils; and of colleges 8, with 43 teachers, and 720 pupils. The number attending school during the year, as returned by families, was 40,293 whites, and 80 free coloured persons—being in the former 6·8 of the white population. Adults unable to read and write—whites 15,684, free coloured 880. There were 16 public, 3 school, and 7 college libraries, having in all 107,472 volumes. The number of places of worship was 1182, with 460,530 sittings; of these, 484 were Methodist, 413 Baptist, 136 Presbyterian, 72 Episcopal, 41 Lutheran, and 17 Roman Catholic.

South Carolina, according to last census, sends 6 representatives (formerly 7) to congress. The legislature consists of a house of representatives and senate. The representatives, 124 in number, are elected for two years, and must be free white men, 21 years of age, and citizens of the state for 3 years, with certain property qualifications. The senators, 45 in number, are chosen for 4 years, one-half going out every two years: they must be free white men of at least 30 years of age, citizens of the state for 5 years, and possessed of a certain value of property. The legislature assembles annually at Columbia. The governor is elected by the senate and house of representatives jointly for two years, and is not re-eligible until the expiry of 4 years. The judiciary consists of a law and an equity court of appeals, courts for correction of errors, of common pleas, and general sessions, &c. Courts of common pleas and general sessions are held in each district twice a-year.

Caroline Islands || Carpathian Mountains.

The militia force in 1850 consisted of 55,209 men, of whom 2591 were commissioned officers. The revenue for year ending 30th Sept. 1852 was $739,696, and the expenditure $359,913: the absolute debt was $1,914,438, and the contingent $1,051,422: total property of the state $5,240,467. (De Bows' *Industrial Resources of the South and West; Gazetteer of the United States; Statistics of the United States; American Almanac*, &c.)

CAROLINE ISLANDS, or NEW PHILIPPINES, are upwards of 400 small islands in the Pacific Ocean, arranged in numerous groups, between Lat. N. 6. and 11., and Long. E. 138. and 163. The principal groups are Yap, Hogol, Ualan, &c. The inhabitants belong to the Malay race, and subsist chiefly by fishing.

CAROLINE *Books*, the name of four books composed by order of Charlemagne, to refute the second council of Nice.

CAROLOSTADT, or CARLOSTADT (*Andrew Bodenstein*), one of the Reformers, was a canon and archdeacon at Wittemberg when he became acquainted with Luther, who converted Carlostadt to his opinions. He was associated with the great Reformer in his early struggles against the Romish Church; but differing from him in regard to the Eucharist, and afterwards being suspected of favouring the Anabaptists, his intimacy with Luther was broken, and a partial reconciliation was effected only a short while before his death. He was for some time minister at Orlamund in Thuringia, but afterwards professor at Zurich and Basle, at which latter place he died in 1541 or 1543. He was the first Reformer who entered into the matrimonial state.

CAROLUS, an old English broad piece of gold, struck under Charles I., and worth twenty shillings. Also a small copper coin, mixed with a little silver, struck under Charles VIII. of France, and worth twelve deniers.

CAROMEL, or CARAMEL, the name given to a dark-brown porous mass obtained from sugar by exposing it to a heat of from 400° to 430°. It is greatly used to colour various liquors, as brandy, beer, &c. See BREWING, p. 331.

CAROOR, a town of Hindustan, in the British district of Coimbetoor, presidency of Madras. It is situated on the north bank of the Ambrawati, or Caroor river, and contains above 1000 houses. The Caroor was the ancient boundary between the dominions of Mysore and Trichinopoly. It was taken by the British in 1760. It is 42 miles west from Trichinopoly. E. Long. 78. 9., N. Lat. 10. 58.

CARORA, a well-built town of Venezuela, in the province of Coro, 94 miles S.S.W. of the town of that name. Pop. probably about 6000. It has manufactures of leather, ropes, and hammocks; and carries on a considerable trade in aromatic balsams, gums, and agricultural productions.

CAROTIDS, two arteries of the neck, which convey the blood from the aorta to the brain.

CAROUGE, a town in the canton of Geneva, pleasantly situated on the Arve, and connected with the city of Geneva by a bridge. Pop. 4000.

CARP. See ICHTHYOLOGY, and ANGLING.

CARPÆA, in *Grecian Antiquity*, a kind of mimetic dance peculiar to the Ænianians and Magnesians. It was performed by two persons, the one representing a labourer, the other a robber. The labourer, laying by his arms, began to plough and sow, but looking warily around as if afraid of being surprised. The robber at length appears, and the labourer seizes his arms and fights in defence of his oxen. Sometimes the robber was overcome, sometimes the labourer—the victor's reward being the oxen and plough. The design of this exercise was to accustom the peasants to defend themselves against the attacks of ruffians. (Xen. *Anab.* vi.; Athen. i.; Maxim. Tyr. *Diss.* xxviii.)

CARPATHIAN MOUNTAINS, or KRAPACKS, a great central European chain, inclosing Transylvania and Hungary, in a curve 800 miles long, the eastern point of which

rests on the Danube at Orsova, the western on the same river at Presburg. It forms the main water-shed between the northern seas and the Black Sea, and varies in elevation from 200 to nearly 9000 feet. See HUNGARY and TRANSYLVANIA.

CARPATHUS, the ancient name of the island of Scarpanto, about 30 miles S.W. of Rhodes. The surrounding sea was called *Carpathium Mare* from this island.

CARPENTARIA, GULF OF, an extensive arm of the sea deeply indenting the north coast of Australia, between S. Lat. 10. 40. and 17. 30., and E. Long. 136. and 142. It averages 350 miles in length and breadth, and contains numerous islands.

CARPENTER, LANT, LL.D., was born at Stourbridge in 1780. He studied at Glasgow, and was for some time minister of a dissenting congregation in Exeter, but afterwards removed to Bristol. He was drowned during a voyage between Leghorn and Naples, in 1840. His works are principally controversial. He was joined with the Rev. Dr William Shepherd, and the Rev. Jeremiah Joyce, in a valuable work entitled *Systematic Education.*

CARPENTER (French *charpentier*, Lat. *carpentarius*), an artificer who works in timber.

CARPENTRAS, capital of an arrondissement of the same name, department of Vaucluse, France, on the Auzon, 15 miles N.E. of Avignon. It is well built, but the streets are mostly narrow and filthy. It is surrounded by old walls. Public buildings, the cathedral, rebuilt in 1405; a palace of justice, formerly the episcopal palace; an aqueduct of 48 arches, finished in 1734; a hospital; and the remains of a Roman triumphal arch. It has a theatre, public library, and museum; also distilleries, dye-works, tanneries, chemical works, and a considerable trade in silk, madder, honey, wax, olive oil, &c. It was anciently an important Roman city. Pop. (1851) of city 10,473, of arrondissement 57,034.

CARPENTRY.

WE must begin by informing our readers, that the bulk of the present article was written by the late Professor Robison, in order to form, with those on ROOF, and STRENGTH OF MATERIALS, also written by him for this Encyclopædia, a uniform system of the most useful departments of practical mechanics, deduced, in the same familiar and elementary manner, from the simple principles of the composition of forces. In here reprinting his contribution, we shall premise some introductory observations, which may be considered as a retrospective summary of the doctrine of Passive Strength, accompanied by some of the most useful propositions respecting the resistance of elastic substances, derived from the principles which have been already laid down in our article BRIDGE; and subjoining a few notes on such passages as may appear to require further illustration or correction. Some of the demonstrations will be partly borrowed from a work which has been published since the death of Professor Robison, but others will be more completely original; and of the remarks, the most important will probably be those which relate to the form and direction of the abutment of rafters; a subject which seems to have been very incorrectly treated by former writers on Carpentry.[1]

I.—ABSTRACT OF THE DOCTRINE OF PASSIVE STRENGTH.

The effects of forces of different kinds, on the materials employed in the mechanical arts, require to be minutely examined in the arrangement of every work dependent on them; and of these effects, as exhibited in a solid body at rest, we may distinguish seven different varieties; the extension of a substance acting simply as a tie; the compression of a block supporting a load above it; the detrusion of an axis resting on a support close to its wheel, and resisting by its lateral adhesion only; the flexure of a body bent by a force applied unequally to its different parts; the torsion or twisting, arising from a partial detrusion of the external parts in opposite directions, while the axis retains its place; the alteration or permanent change of a body which settles, so as to remain in a new form, when the force is withdrawn; and lastly, the fracture, which consists in a complete separation of parts before united, and which has been the only effect particularly examined by the generality of authors on the strength of materials.

The analogy of the laws of extension and compression has been demonstrated in a former article (BRIDGE), and their connection with flexure has been investigated; but it is not easy to compare them directly with the resistance opposed to a partial detrusion, the effects of which are only so far understood as they are exhibited in the phenomena of twisting; and these appear to justify us in considering the resistance of lateral adhesion as a primitive force, deduced from the rigidity or solidity of the substance, and proportional to the deviation from the natural situation of the particles. The resistance exhibited by steel wire, when twisted, bears a greater proportion to that of brass than the resistance to extension or compression, but the forces agree in being independent of the hardness produced by tempering.

Flexure may be occasioned either by a transverse or by a longitudinal force. When the force is transverse, the extent of the flexure is nearly proportional to its magnitude; but when it is longitudinal, there is a certain magnitude which it must exceed in order to produce, or rather to continue, the flexure, if the force be applied exactly at the axis. But it is equally true that the slightest possible force applied at a distance from the axis, however minute, or with an obliquity however small, or to a beam already a little curved, will produce a certain degree of flexure; and this observation will serve to explain some of the difficulties and irregularities which have occurred in making experiments on beams that are exposed to longitudinal pressure.

Stiffness, or the power of resisting flexure, is measured by the force required to produce a given minute change of form. For beams similarly fixed, it is directly proportional to the breadth and the cube of the depth, and inversely to the cube of the length. Thus a beam or bar two yards long will be equally stiff with a beam one yard, provided that it be either twice as deep or eight times as broad. If the ends of a beam can be firmly fixed, by continuing them to a sufficient distance, and keeping them down by a proper pressure, the stiffness will be four times as great as if the ends were simply supported. A hollow substance, of given weight and length, has its stiffness

[1] These introductory observations to Professor Robison's article, and the notes subjoined to it, were written by the late Dr Thomas Young.

nearly proportional to the square of the diameter; and hence arises the great utility of tubes when stiffness is required, this property being still more increased by the expansion of the substance than the ultimate strength. It is obvious that there are a multiplicity of cases in carpentry where stiffness is of more importance than any other property, since the utility as well as beauty of the fabric might often be destroyed by too great a flexibility of the materials.

If we wish to find how much a beam of fir will sink when it is loaded in the middle, we may multiply the cube of the length in inches by the given weight in pounds, and divide by the cube of the depth, and by ten million times the breadth; but, on account of the unequal texture of the wood, we must expect to find the bending somewhat greater than this in practice, besides that a large weight will often produce an alteration, or permanent settling, which will be added to it: a beam of oak will also sink a little more than a beam of fir with the same weight.

With respect to torsion, the stiffness of a cylindrical body varies directly as the fourth power of the diameter, and inversely in the simple proportion of the length: it does not appear to be changed by the action of any force tending to lengthen or to compress the cylinder; and it may very possibly bear some simple relation to the force of cohesion, which has not yet been fully ascertained; but it appears that, in an experiment of Mr Cavendish, the resistance of a cylinder of copper to a twisting force, acting at its surface, was about $\frac{1}{100}$ of the resistance that the same cylinder would have opposed to direct extension or compression.

Alteration is often an intermediate step between a temporary change and a complete fracture. There are many substances which, after bending to a certain extent, are no longer capable of resuming their original form; and in such cases it generally happens that the alteration may be increased without limit, until complete fracture takes place, by the continued operation of the same force which has begun it, or by a force a little greater. Those substances which are the most capable of this change are called ductile; and the most remarkable are gold, and a spider's web. When a substance has undergone an alteration by means of its ductility, its stiffness, in resisting small changes on either side, remains little or not at all altered. Thus, if the stiffness of a spider's web, in resisting torsion, were sufficient at the commencement of an experiment to cause it to recover itself, after being twisted in an angle of ten degrees, it would return ten degrees, and not more, after having been twisted round a thousand times. The ductility of all substances capable of being annealed is greatly modified by the effects of heat. Hard steel, for example, is incomparably less subject to alteration than soft, although in some cases more liable to fracture; so that the degree of hardness requires to be proportioned to the uses for which each instrument is intended; although it was proved by Coulomb, and has since been confirmed by other observers, that the primitive stiffness of steel, in resisting small flexures, is neither increased nor diminished by any variation in its temper.

The strength of a body is measured by the force required completely to overcome the corpuscular powers concerned in the aggregation of its particles, and it is jointly proportional to the primitive stiffness and to the toughness of the substance, that is, to the degree in which it is capable of a change of form without permanent alteration. It becomes, however, of importance in some cases to consider the measure of another kind of strength, which has sometimes been called resilience, or the power of resisting a body in motion, and which is proportional to the strength and the toughness conjointly, that is, to the stiffness and the square of the toughness. Thus, if we double the length of a given beam, we reduce its absolute strength to one half, and its stiffness to one eighth; but since the toughness, or the space through which it will continue to resist, is quadrupled, the resilience will be doubled, and it would require a double weight to fall from the same height, or the same weight to fall from a double height, in order to overcome its whole resistance. If we wish to determine the resilience of a body from an experiment on its strength, we must measure the distance through which it recedes or is bent previously to its fracture; and it may be shown that a weight which is capable of breaking it by pressure, would also break it by impulse if it moved with the velocity acquired by falling from a height equal to half the deflection. Thus, if a beam or bar were broken by a weight of 100 pounds, after being bent six inches without alteration, it would also be broken by a weight of 100 pounds falling from a height of three inches, or moving in a horizontal direction with a velocity of four feet in a second, or by a weight of one pound falling from a height of 300 inches. This substitution of velocity for quantity of matter has, however, one limit, beyond which the velocity must prevail over the resistance, without regard to the quantity of matter; and this limit is derived from the time required for the successive propagation of the pressure through the different parts of the substance, in order that they may participate in the resistance. Thus, if a weight fell on the end of a bar or column with a velocity of 100 feet in a second, and the substance could only be compressed $\frac{1}{200}$ of its length, without being crushed, it is obvious that the pressure must be propagated through the substance with a velocity of 20,000 feet in a second, in order that it might resist the stroke; and, in general, a substance will be crushed or penetrated by any velocity exceeding that which is acquired by a body falling from a height, which is to half that of the modulus of elasticity of the substance, as the square of the greatest possible change of length is to the whole length. From the consideration of the effect of rigidity in lessening the resilience of bodies, we may understand how a diamond, which is capable of resisting an enormous pressure, may be crushed with a blow of a small hammer, moving with a moderate velocity. It is remarkable that, for the same substance in different forms, the resilience is in most cases simply proportional to the bulk or weight, while almost every other kind of resistance is capable of infinite variation by change of form only.

The elaborate investigations of M. Lagrange, respecting the strength and the strongest forms of columns, appear to have been conducted upon principles not altogether unexceptionable; but it is much easier to confute the results than to follow the steps of the computations. One great error is the supposition that columns are to be considered as elastic beams, bent by a longitudinal force; while, in reality, a stone column is never slender enough to be bent by a force which it can bear without being crushed and even for such columns as are capable of being bent by a longitudinal force, M. Lagrange's determinations are in several instances inadmissible. He asserts, for example, that a cylinder is the strongest of all possible forms, and that a cone is stronger than any conoid of the same bulk; but it appears to be demonstrable in a very simple manner, and upon incontestable principles, that a conoidal form may be determined, which shall be stronger than either a cone or a cylinder of the same bulk.

When a column is crushed, its resistance to compression seems to depend in great measure on the force of lateral adhesion, assisted by a kind of internal friction, dependent on the magnitude of the pressure; and it commonly gives way by the separation of a wedge in an

oblique direction. If the adhesion were simply proportional to the section, it may be shown that a square column would be most easily crushed when the angle of the wedge is equal to half of a right angle; but if the adhesion is increased by pressure, this angle will be diminished by half the angle of repose appropriate to the substance. In a wedge separated by a direct force from a prism of cast iron, the angle was found equal to $32\frac{1}{2}°$, consequently the angle of repose was $2 \times 12\frac{1}{2}° = 25°$, and the internal friction to the pressure as 1 to ·466, the tangent of this angle; there was, however, a little bubble in the course of the fracture, which may have changed its direction in a slight degree. The magnitude of the lateral adhesion is measured by twice the height of the wedge, whatever its angle may be. In this instance the height was to the depth as 1·57 to 1, consequently the surface, affording an adhesion equal to the force, was somewhat more than three times as great as the transverse section, and the lateral adhesion of a square inch of cast iron would be equal to about 46,000 pounds; the direct cohesive force of the same iron was found by experiment equal to about 20,000 pounds for a square inch. It is obvious that experiments on the strength of a substance in resisting compression ought to be tried on pieces rather longer than cubes, since a cube would not allow of the free separation of a single wedge so acute as was observed in this experiment; although, indeed, the force required to separate a shorter wedge on each side would be little or no greater than for a single wedge. The same consideration of the oblique direction of the plane of easiest fracture would induce us to make the outline of a column a little convex externally, as the common practice has been; for a circle cut out of a plank possesses the advantage of resisting equally in every section, and consequently of exhibiting the strongest form, when there is no lateral adhesion; and in the case of an additional resistance proportional to the pressure, the strongest form is afforded by an oval consisting of two circular segments, each containing twice the angle formed by the plane of fracture with the horizon. If we wish to obtain a direct measure of the lateral adhesion, we must take care to apply the forces concerned at a distance from each other not greater than one sixth of the depth of the substance, otherwise the fracture will probably be rather the consequence of flexure than of detrusion. Professor Robison found this force in some instances twice as great as the direct cohesion, or nearly in the same proportion as it appears to have been in the experiment on the strength of cast iron; Mr Coulomb thinks it most commonly equal only to the cohesion; and in fibrous substances, especially where the fibres are not perfectly straight, the repulsive strength is generally much less than would be inferred from this equality, and sometimes even less than the cohesive strength.

It is well known that the transverse strength of a beam is directly as the breadth and as the square of the depth, and inversely as the length; and the variation of the results of some experiments from this law can only have depended on accidental circumstances. If we wish to find the number of hundredweights that will break a beam of oak supported at both ends, supposing them to be placed exactly on the middle, we may multiply the square of the depth in inches by 100 times the breadth, and divide by the length; and we may venture in practice to load a beam with at least an eighth as much as this, or, in case of necessity, even a fourth. And if the load be distributed equally throughout the length of the beam, it will support twice as much; but for a beam of fir the strength is somewhat less than for oak. A cylinder will bear the same curvature as the circumscribing prism, and it may be shown that its strength, as well as its stiffness, is to that of the prism as one fourth of its bulk is to one third of the bulk of the prism. The strength of a beam supported at its extremities may be doubled by firmly fixing the ends where it is practicable; and we have already seen that the stiffness is quadrupled: but the resilience remains unaltered, since the resistance is doubled, and the space through which it acts is reduced to a half. It is therefore obviously of importance to consider the nature of the resistance that is required from the fabric which we are constructing. A floor, considered alone, requires to be strong; but in connection with a ceiling, its stiffness requires more particular attention, in order that the ceiling may remain free from cracks. A coach-spring requires resilience for resisting the relative motions of the carriage, and we obtain this kind of strength as effectually by combining a number of separate plates, as if we united them into a single mass, while we avoid the stiffness, which would render the changes of motion inconveniently abrupt.

In all calculations respecting stiffness, it is necessary to be acquainted with the modulus of elasticity, which may be found for a variety of substances in the annexed table.

Height of the Modulus of Elasticity in Thousands of Feet.

Iron and steel	10,000	Fir wood	10,000
Copper	5,700	Elm	8,000
Brass	5,000	Beech	8,000
Silver	3,240	Oak	5,060
Tin	2,250	Box	5,050
Crown glass	9,800	Ice	850

II.—PROPOSITIONS RELATING TO FLEXURE.

A. *The stiffness of a cylinder is to that of its circumscribing rectangular prism, as three times the bulk of the cylinder is to four times that of the prism.*

We may consider the different strata of the substance as acting on levers equal in length to the distance of each from the axis; for although there is no fixed fulcrum at the axis, yet the whole force is the same as if such a fulcrum existed, since the opposite actions of the opposite parts would relieve the fulcrum from all pressure. Then the tension of each stratum being also as the same distance x, and the breadth of the stratum being called $2y$, the fluxion of the force on either side of the axis will be $2x^2ydx$, while that of the force of the prism, the radius being r, is $2rx^2dx$. Now z being the area of half the portion included between the stratum and the axis, of which the fluxion is ydx, the fluxion of $z - \frac{y^3x}{rr}$ will be

$$ydx - \frac{y^3dx}{r^2} - \frac{3y^2xdy}{r^2}$$

$$= ydx\left(1 - \frac{y^2}{r^2}\right) - \frac{3yx}{r^2}\,ydy.$$

But $1 - \frac{y^2}{r^2} = \frac{x^2}{r^2}$, and $-ydy = xdx$,

therefore the fluxion is

$$\frac{x^2ydx}{r^2} + \frac{3x^2ydx}{r^2} = \frac{4x^2ydx}{r^2};$$

consequently the fluent of $2x^2ydx$ is $\frac{1}{2}r^2z - \frac{1}{2}y^3x$, which, when $y = 0$, becomes $\frac{1}{2}r^2z$, or one fourth of the product of the square of the radius by the area of the section, while the fluent of $2rx^2dx$, that is, $\frac{2}{3}rx^3$, the force of the prism, becomes $\frac{2}{3}r^4$ or $\frac{1}{3}r^2 \times 2r^2$, one third of the product of the same square into the area of the section of the prism.

Hence the radius of curvature of a cylindrical column, instead of $\frac{Maa}{12fy}$ (Art. BRIDGE, Prop. G), will be $\frac{Maa}{16fy}$, the weight of the modulus M decreasing in the same propor-

tion as the bulk when the prism is reduced to a cylinder. The force is supposed in this proposition to be either transverse or applied at a considerable distance from the axis; but the error will not be material in any other case.

B. *When a longitudinal force f is applied to the extremities of a straight prismatic beam, at the distance b from the axis, the deflection of the middle of the beam will be* $b\left(\text{SECANT}\left[\sqrt{\left(\frac{3f}{M}\right)}\cdot\frac{e}{a}\right]-1\right)$; M *being the weight of the modulus, e the length of the beam, and a its depth.*

The curvature being proportional to the distance from the line of direction of the force, or to the ordinate, when that line is considered as the absciss, the elastic curve must in this case initially coincide with a portion of the harmonic curve, well known for its utility in the resolution of a variety of problems of this kind. Now if the half length of the complete curve be called k, corresponding to a quadrant of the generating circle, and the greatest ordinate y, c being the quadrant of a circle of which the radius is unity, the radius of curvature r corresponding to y will be $\frac{kk}{ccy}$, that is, a third proportional to y and $\frac{k}{c}$ the radius of the generating circle; consequently $\frac{\text{M}aa}{12fy} = \frac{kk}{ccy}$, $kk = \frac{\text{M}aacc}{12f}$, and $k = \frac{1}{2}\sqrt{\frac{\text{M}}{3f}}\cdot ac$; but by the nature of the curve, $y : b = 1 : \cos.\frac{ec}{2k} = \sec.\frac{ec}{2k} : 1$, and $y = b\sec.\frac{ec}{2k} = b\sec.\sqrt{\frac{3f}{\text{M}}}\cdot\frac{e}{a}$, which is the ordinate at the middle; and the deflection from the natural situation is $y - b$.

It follows that, since the secant of the quadrant is infinite, when $\sqrt{\frac{3f}{\text{M}}}\cdot\frac{e}{a}$ becomes equal to c, the deflection will be infinite, and the resistance of the column will be overcome, however small the distance b may be taken, provided that it be of finite magnitude; and since in this case $\frac{3fee}{\text{M}aa} = cc$, $f = \frac{\text{M}aacc}{3ee} = \cdot 8225\ \text{M}\frac{aa}{ee}$, which is the utmost force that the column will bear: and for a cylinder we find, by the same reasoning, $f = \frac{\text{M}aacc}{4ee} = \cdot 6169\ \text{M}\frac{aa}{ee}$. If b be supposed to vanish, we shall have in theory an equilibrium without flexure; but since it will be tottering, it cannot exist in nature.

By applying this determination to the strength of wood and iron, compared with the modulus of elasticity, it appears that a round column or a square pillar of either of these substances cannot be bent by any longitudinal force applied to the axis, which it can withstand without being crushed, unless its length be greater than twelve or thirteen times its thickness respectively; nor a column or pillar of stone, unless it be forty or forty-five times as long as it is thick. Hence we may infer, as a practical rule, that every piece of timber or iron intended to withstand any considerable compressing force, should be at least as many inches in thickness as it is feet in length, in order to avoid the loss of force which necessarily arises from curvature.

C. *When a beam, fixed at one end, is pressed by a force in a direction deviating from the original position of the axis in a small angle, of which the tangent is t, the deflection becomes* $d = at\frac{\text{M}}{12f}\ \text{TANG.}\left(\sqrt{\frac{12f}{\text{M}}}\cdot\frac{e}{a}\right)$.

The inclination of the curve to the absciss being inconsiderable, it will not differ sensibly from a portion of a harmonic curve; and supposing the quadrantal length of this curve k, we have again, as in the last proposition, $k = \frac{1}{2}\sqrt{\frac{\text{M}}{3f}}\cdot ac$, or, for a cylinder, $k = \frac{1}{4}\sqrt{\frac{\text{M}}{f}}\cdot ac$. Now, the tangent of the inclination of the harmonic curve varies as the sine of the angular distance from the middle; consequently, as $\text{SIN.}\frac{k-e}{k}\cdot c$, or $\cos.\frac{ec}{k}$, is to the radius, so is the tangent t, expressing the difference of inclination of the end of the beam and the direction of the force, which is also that of the middle of the supposed curve, to the tangent of the extreme inclination of the curve to its absciss, which will therefore be $t\ \text{SEC.}\frac{ec}{k}$; consequently the greatest ordinate will be $\frac{kt}{c}\ \text{SEC.}\frac{ec}{k}$, and since the ordinates are as the sines of the angular distances from the origin of the curve, the ordinate at the fixed end of the beam, corresponding to the angle $\frac{ec}{k}$, that is, the deflection, will be $\frac{kt}{c}\ \text{SEC.}\frac{ec}{k}.\ \text{SIN.}\frac{ec}{k} = \frac{kt}{c}\ \text{TANG.}\frac{ec}{k} = \frac{1}{2}\sqrt{\frac{\text{M}}{3f}}\cdot at\ \text{TANG.}\frac{2e}{a}\sqrt{\frac{3f}{\text{M}}}$, or, for a cylinder, $\frac{1}{4}\sqrt{\frac{\text{M}}{f}}\cdot at\ \text{TANG.}\frac{4e}{a}\sqrt{\frac{f}{\text{M}}}$.

By means of this proposition we may determine the effect of a small lateral force in weakening a beam or pillar which is at the same time compressed longitudinally by a much greater force, considering the parts on each side of the point to which the lateral force is applied, as portions of two beams, bent in the manner here described, by a single force slightly inclined to the axis.

D. *A bar fixed at one end, and bent by a transverse force applied to the other end, assumes initially the form of a cubic parabola, and the deflection at the end is* $d = \frac{4e^3f}{\text{M}aa}$.

The ordinate of a cubic parabola varying as x^3, its second fluxion varies as $6x\,(dx)^2$, or since the first fluxion of the absciss is constant, simply as the absciss x, measured from the vertex of the parabola, which must therefore be situated at the end to which the force is applied, and the absciss must coincide with the tangent of the bar. But if we begin from the other end, we must substitute $e-x$ for x, and the second fluxion of the ordinate will be as $6\,(e-x)\,(dx)^2$, the first as $6exdx - 3x^2dx$, and the fluent as $3ex^2 - x^3$, which, when $x = e$, becomes $2e^3$, while it would have been $3e^3$ if the curvature had been uniform, and the second fluxion had been everywhere $6e(dx)^2$. Now the radius of curvature at the fixed end being $r = \frac{\text{M}aa}{12ef}$, and the versed sine of a small portion of a circle being equal to $\frac{ee}{2r}$, this versed sine will be expressed by $\frac{6e^3f}{\text{M}aa}$; and two thirds of this, or $\frac{4e^3f}{\text{M}aa}$, will be the actual deflection.

E. *The depression of a bar, fixed horizontally at one end, and supporting only its own weight, is* $d = \frac{3e^4}{2maa}$; *m being the height of the modulus of elasticity.*

The curvature here varies as the square of the distance from the end, because the strain is proportional to the weight of the portion of the bar beyond any given point, and to the distance of its centre of gravity conjointly, that is, to $(e-x)\ \frac{1}{2}\,(e-x)$, so that if the second fluxion

Carpentry.

at the fixed end be as $e^2(dx)^2$, it will elsewhere be as $(e-x)^2(dx)^2$; and the corresponding first fluxions being e^2xdx and $e^2xdx - ex^2dx + \frac{1}{3}x^3dx$, the fluents will be $\frac{1}{2}e^2x^2$, and $\frac{1}{2}e^2x^2 - \frac{1}{3}ex^3 + \frac{1}{12}x^4$, or, when $x = e$, $\frac{1}{12}e^4$, and $(\frac{1}{2} - \frac{1}{3} + \frac{1}{12})e^4 = \frac{1}{4}e^4$; consequently the depression must be half the versed sine in the circle of greatest curvature. Now the radius of curvature $\frac{Maa}{12fy}$ becomes here $\frac{Maa}{6ef}$, the force being applied at the distance $\frac{1}{2}e$; and since the weight of the bar is to that of the modulus of elasticity in the proportion of the respective lengths, we have $\frac{f}{M} = \frac{e}{m}$, and $r = \frac{maa}{6ee}$, and the versed sine for the ordinate e will be $\frac{3e^4}{maa}$, half of which is the actual depression.

F. *The depression of the middle of a horizontal bar, fixed at both ends, and supporting its own weight only, is* $d = \frac{5e^4}{32maa}$.

The transverse force at each point of such a bar, resisted by the lateral adhesion, is as the distance x from the middle (*Art.* BRIDGE, under Prop. L); but this force is proportional to the first fluxion of the strain or curvature, consequently the curvature itself must vary as the corrected fluent of $\pm xdx$, taking here the negative sign, because the curvature diminishes as x increases; and the corrected fluent will be $\frac{1}{4}e^2 - x^2$, since it must vanish when $x = \frac{1}{2}e$; the first fluxion of the ordinate will then be $\frac{1}{4}e^2xdx - \frac{1}{3}x^3dx$, and the fluent $\frac{1}{8}e^2x^2 - \frac{1}{12}x^4$, or for the whole length $\frac{1}{2}e$, $\frac{1}{192}e^4$, instead of $\frac{1}{32}$, or $\frac{6}{192}$, which would have been its value if the curvature had been equal throughout. Now the strain at the middle is the difference of the opposite strains produced by the forces acting on either side; and these are the half weight acting at the mean distance $\frac{1}{4}e$, and the resistance of the support, which is equal to the same half weight, but acts at the distance $\frac{1}{2}e$, the difference being equivalent to the half weight, acting at the distance $\frac{1}{4}e$, so that the curvature at the middle is the same as if the bar were fixed there, and loose at the ends; that is, as in the last proposition, substituting $\frac{1}{2}e$ for e, $r = \frac{2maa}{3ee}$; and the versed sine at the distance $\frac{1}{2}e$ being $\frac{e^2}{8r}$, or $\frac{3e^4}{16maa}$, $\frac{5}{6}$ of this will be $\frac{5e^4}{32maa}$. This demonstration may serve as an illustration of two modes of considering the effect of a strain, which have not been generally known, and which are capable of a very extensive application.

It follows that where a bar is equally loaded throughout its length, the curvature at the middle is half as great as if the whole weight were collected there, the strain derived from the resistance of the support remaining in that case uncompensated. The depression produced by the divided weight will be $\frac{5}{8}$ as great as by the single weight, since $\frac{5}{6} \times \frac{1}{2}$ is to $\frac{2}{3}$ as 5 to 8. M. Dupin found the proposition, by many experiments, between $\frac{2}{3}$ and $\frac{3}{5}$; and $\frac{5}{8}$ is a very good mean for representing these results.

III.—ELEMENTS OF CARPENTRY.

Definition.

"Carpentry is the art of framing timber for the purposes of architecture, machinery, and, in general, for all considerable structures."

It is not intended in this article to give a full account of carpentry as a mechanical art, or to describe the various ways of executing its different works, suited to the variety of materials employed, the processes which must be followed for fashioning and framing them for our purposes, and the tools which must be used, and the manner in which they must be handled. This would be an occupation for volumes, and, though of great importance, must be entirely omitted here. Our only aim at present will be to deduce, from the principles and laws of mechanics, and the knowledge which experience, and judicious inferences from it, have given us concerning the strength of timber, in relation to the strain laid on it, such maxims of construction as will unite economy with strength and efficacy.

Carpentry.

This object is to be attained by a knowledge, 1*st*, of the strength of our materials, and of the absolute strain that is to be laid on them; 2*dly*, of the modifications of this strain, by the place and direction in which it is exerted, and the changes that can be made by a proper disposition of the parts of our structure; and, 3*dly*, having disposed every piece in such a manner as to derive the utmost advantage from its relative strength, we must know how to form the joints and other connections in such a manner as to secure the advantages derived from this disposition.

An important branch of mechanical science.

This is evidently a branch of mechanical science which makes carpentry a *liberal* art, constitutes part of the learning of the ENGINEER, and distinguishes him from the workman. Its importance in all times and states of civil society is manifest and great. In the present condition of these kingdoms, raised by the active ingenuity and energy of our countrymen to a pitch of prosperity and influence unequalled in the history of the world, a condition which consists chiefly in the superiority of our manufactures, attained by prodigious multiplication of engines of every description, and for every species of labour, the Science (so to term it) of carpentry is of immense consequence. We regret therefore exceedingly that none of our celebrated artists have done honour to themselves and their country, by digesting into a body of consecutive doctrines the results of their experience, so as to form a system from which their pupils might derive the first principles of their education. The many volumes called Complete Instructors, Manuals, &c. take a much humbler flight, and content themselves with instructing the mere workman; or sometimes give the master builder a few approved forms of roofs and other framings, with the rules for drawing them on paper, and from thence forming the working draughts which must guide the saw and the chisel of the workman. Hardly any of them offer any thing that can be called a principle, applicable to many particular cases, with the rules for this adaptation. We are indebted for the greatest part of our knowledge of this subject to the labours of literary men, chiefly foreigners, who have published in the memoirs of the learned academies dissertations on different parts of what may be termed the *Science of Carpentry*. It is singular that the members of the Royal Society of London, and even of that established and supported for the encouragement of the arts, have contributed so little to the public instruction in this respect. We have observed some beginnings of this kind, such as the last part of Nicholson's *Carpenter's and Joiner's Assistant*; and it is with pleasure we can say, that we were told by the editor this work was prompted in a great measure by what has been delivered in our articles ROOF and STRENGTH OF MATERIALS. It abounds more in important and new observations than any book of the kind that we are acquainted with. We again call on such as have given a scientific attention to this subject, and pray that they would render a meritorious service to their country by imparting the result of their researches. The very limited nature of this work does not allow us to treat the subject in de-

Principally indebted to foreigners for a knowledge of this subject.

Carpentry. tail; and we must confine our observations to the fundamental and leading propositions.

Theory founded on what.

The theory, so to term it, of carpentry is founded on two distinct portions of mechanical science, namely, a knowledge of the strains to which framings of timber are exposed, and a knowledge of their *relative* strength.

We shall therefore attempt to bring into one point of view the propositions of mechanical science that are more immediately applicable to the art of carpentry, and are to be found in various articles of our work, particularly Roof and Strength of Materials. From these propositions we hope to deduce such principles as shall enable an attentive reader to comprehend distinctly what is to be aimed at in framing timber, and how to attain this object with certainty; and we shall illustrate and confirm our principles by examples of pieces of carpentry which are acknowledged to be excellent in their kind.

Composition and resolution of forces.

The most important proposition of general mechanics to the carpenter is that which exhibits the composition and resolution of forces; and we beg our practical readers to endeavour to form very distinct conceptions of it, and to make it very familiar to their minds. When accommodated to their chief purposes, it may be thus expressed:

1. If a body, or any part of a body, be at once pressed in the two directions AB, AC (fig. 1, Plate CLIX.), and if the intensity or force of those pressures be in the proportion of these two lines, the body is affected in the same manner as if it were pressed by a single force acting in the direction AD, which is the diagonal of the parallelogram ABDC formed by the two lines, and whose intensity has the same proportion to the intensity of each of the other two that AD has to AB or AC.

Such of our readers as have *studied* the laws of motion, know that this is fully demonstrated. Such as wish for a very accurate view of this proposition will do well to read the demonstration given by D. Bernoulli, in the first volume of the *Comment. Petropol.*, and the improvement of this demonstration by D'Alembert in his *Opuscules* and in the *Comment. Taurinens.* The practitioner in carpentry will get more useful confidence in the doctrine, if he will shut his book, and verify the theoretical demonstrations by actual experiments. They are remarkably easy and convincing. Therefore it is our request that the artist, who is not so habitually acquainted with the subject, do not proceed further till he has made it quite familiar to his thoughts. Nothing is so conducive to this as the actual experiment; and since this only requires the trifling expense of two small pulleys and a few yards of whipcord, we hope that none of our practical readers will omit it: they will thank us for this injunction.

Illustrated by experiment.

2. Let the threads A*d*, AF*b*, and AE*c* (fig. 2), have the weights *d*, *b*, and *c*, appended to them, and let two of the threads be laid over the pulleys F and E. By this apparatus the knot A will be drawn in the directions AB, AC, and AK. If the sum of the weights *b* and *c* be greater than the single weight *d*, the assemblage will of itself settle in a certain determined form: if you pull the knot A out of its place, it will always return to it again, and will rest in no other position. For example, if the three weights are equal, the threads will always make equal angles, of 120 degrees each, round the knot. If one of the weights be three pounds, another four, and the third five, the angle opposite to the thread stretched by five pounds will always be square, &c. When the knot A is thus in equilibrio, we must infer that the action of the weight *d*, in the direction A*d*, is in direct opposition to the combined action of *b* in the direction AB, and of *c* in the direction AC. Therefore, if we produce *d*A to any point D, and take AD to represent the magnitude of the force, or pressure exerted by the weight *d*, the pressures exerted on A by the weights *b* and *c*, in the directions AB, AC, are in fact equivalent to a pressure acting in the direction AD, whose intensity we have represented by AD. If we now measure off by a scale on AF and AE the lines AB and AC, having the same proportions to AD that the weights *b* and *c* have to the weight *d*, and if we draw DB and DC, we shall find DC to be equal and parallel to AB, and DB equal and parallel to AC; so that AD is the diagonal of a parallelogram ABDC. We shall find this always to be the case, whatever are the weights made use of; only we must take care that the weight which we cause to act without the intervention of a pulley be less than the sum of the other two; if any one of the weights exceeds the sum of the other two, it will prevail, and drag them along with it.

Carpentry.

Now since we know that the weight *d* would just balance an equal weight *g*, pulling directly upwards by the intervention of the pulley G; and since we see that it just balances the weights *b* and *c*, acting in the directions AB, AC; we must infer that the knot A is affected in the same manner by those two weights, or by the single weight *g*; and therefore that *two pressures, acting in the directions and with the intensities* AB, AC, *are equivalent to a single pressure having the direction and proportion of* AD. In like manner, the pressures AB, AK, are equivalent to AH, which is equal and opposite to AC. Also AK and AC are equivalent to AI, which is equal and opposite to AB.

We shall consider this combination of pressures a little more particularly.

Suppose an upright beam BA (fig. 3), pushed in the direction of its length by a load B, and abutting on the ends of two beams AC, AD, which are firmly resisted at their extreme points C and D, which rest on two blocks, but are nowise joined to them; these two beams can resist no way but in the directions CA, DA, and therefore the pressures which they sustain from the beam BA are in the directions AC, AD. We wish to know how much each sustains: Produce BA to E, taking AE from a scale of equal parts, to represent the number of tons or pounds by which BA is pressed. Draw EF and EG parallel to AD and AC; then AF, measured on the same scale, will give us the number of pounds by which AC is strained or crushed, and AG will give the strain on AD.

It deserves particular remark here, that the length of AC or AD has no influence on the strain arising from the thrust BA, while the directions remain the same. The effects, however, of this strain are modified by the length of the piece on which it is exerted. This strain compresses the beam, and will therefore compress a beam of double length twice as much. This may change the form of the assemblage. If AC, for example, be very much shorter than AD, it will be much less compressed: the line CA will turn about the centre C, while DA will hardly change its position; and the angle CAD will grow more open, the point A sinking down. The artist will find it of great consequence to pay a very minute attention to this circumstance, and to be able to see clearly the change of shape which necessarily results from these mutual strains. He will see in this the cause of failure in many very great works. By thus changing shape, strains are often produced in places where there were none before, and frequently of the very worst kind, tending to break the beams across.

The dotted lines of this figure show another position of the beam AD'. This makes a prodigious change, not only in the strain on AD', but also in that on AC. Both of them are much increased; AG is almost doubled, and AF is four times greater than before. This addition was

made to the figure to show what enormous strains may be produced by a very moderate force, AE, when it is exerted on a very obtuse angle.[1]

The fourth and fifth figures will assist the most uninstructed reader in conceiving how the very same strains, AF, AG, are laid on these beams, by a weight simply hanging from a billet resting on A, pressing hard on AD, and also leaning a little on AC; or by an upright piece, AE, joggled on the two beams AC, AD, and performing the office of an ordinary king-post. The reader will thus learn to call off his attention from the means by which the strains are produced, and learn to consider them abstractedly merely as strains, in whatever situation he finds them, and from whatever cause they arise.

We presume that every reader will perceive, that the proportions of these strains will be precisely the same if every thing be inverted, and each beam be drawn or pulled in the opposite direction. In the same way that we have substituted a rope and weight in fig. 4, or a king-post in fig. 5, for the loaded beam BA of fig. 3, we might have substituted the framing of fig. 6, which is a very usual practice. In this framing, the batten DA is stretched by a force AG, and the piece AC is compressed by a force AF. It is evident that we may employ a rope or an iron rod hooked on at D, in place of the batten DA, and the strains will be the same as before.

This seemingly simple matter is still full of instruction; and we hope that the well-informed reader will pardon us, though we dwell a little longer on it for the sake of the young artist.

By changing the form of this framing, as in fig. 7, we produce the same strains as in the disposition represented by the dotted lines in fig. 3. The strains on both the battens AD, AC, are now greatly increased.

The same consequences result from an improper change of the position of AC. If it is placed as in fig. 8, the strains on both are vastly increased. In short, the rule is general, that the more open we make the angle against which the push is exerted, the greater are the strains which are brought on the struts or ties which form the sides of the angle.

The reader may not readily conceive the piece AC of fig. 8 as sustaining a compression; for the weight B appears to hang from AC as much as from AD. But his doubts will be removed by considering whether he could employ a rope in place of AC. He cannot; but AD may be exchanged for a rope. AC is therefore a strut, and not a tie.

In fig. 9, Plate CLX., AD is again a strut, butting on the block D, and AC is a tie; and the batten AC may be replaced by a rope. While AD is compressed by the force AG, AC is stretched by the force AF.

If we give AC the position represented by the dotted lines, the compression of AD is now AG′, and the force stretching AC′ is now AF′; both much greater than they were before. This disposition is analogous to fig. 8, and to the dotted lines in fig. 3. Nor will the young artist have any doubts of AC′ being on the stretch, if he consider whether AD can be replaced by a rope. It cannot, but AC′ may; and it is therefore not compressed, but stretched.

In fig. 10 all the three pieces, AC, AD, and AB, are ties, on the stretch. This is the complete inversion of fig. 3; and the dotted position of AC induces the same changes in the forces AF, AG′, as in fig. 3.

Thus have we gone over all the varieties which can happen in the bearings of three pieces on one point. All calculations about the strength of carpentry are reduced to this case; for when more ties or braces meet in a point (a thing that rarely happens), we reduce them to three, by substituting for any two the force which results from their combination, and then combining this with another: and so on.

The young artist must be particularly careful not to mistake the kind of strain that is exerted on any piece of the framing, and suppose a piece to be a brace which is really a tie. It is very easy to avoid all mistakes in this matter by the following rule, which has no exception: (See Note AA.)

Rule for distinguishing the cases of compression and extension.

Take notice of the direction in which the piece acts from which the strain proceeds. Draw a line in that direction *from* the point on which the strain is exerted, and let its length (measured on some scale of equal parts) express the magnitude of this action in pounds, hundreds, or tons. From its *remote* extremity draw lines parallel to the pieces on which the strain is exerted. The line parallel to one piece will necessarily cut the other, or its direction produced. If it cut the piece itself, that piece is compressed by the strain, and it is performing the office of a strut or brace; if it cut its direction produced, the piece is stretched, and it is a tie. In short, the strains on the pieces AC, AD, are to be estimated in the direction of the points F and G *from* the strained point A. Thus, in fig. 3, the upright piece BA, loaded with the weight B, presses the point A in the direction AE; so does the rope AB in the other figures, or the batten AB in fig. 5.

In general, if the straining piece is within the angle formed by the pieces which are strained, the strains which they sustain are of the opposite kind to that which it exerts. If it be pushing, they are drawing; but if it be within the angle formed by their directions produced, the strains which they sustain are of the same kind. All the three are either drawing or pressing. If the straining piece lie within the angle formed by one piece and the produced direction of the other, its own strain, whether compression or extension, is of the same kind with that of the most remote of the other two, and opposite to that of the nearest. Thus, in fig. 9, where AB is drawing, the remote piece AC is also drawing, while AD is pushing or resisting compression.

In all that has been said on this subject, we have not spoken of any joints. In the calculations with which we are occupied at present, the resistance of joints has no share; and we must not suppose that they exert any force which tends to prevent the angles from changing. The joints are supposed perfectly flexible, or to be like compass joints, the pin of which only keeps the pieces together when one or more of the pieces draws or pulls. The carpenter must always suppose them all compass joints when he calculates the thrusts and draughts of the different pieces of his frames. The strains on joints, and their power to produce or balance them, are of a different kind, and require a very different examination.

General expression of the magnitude of the strain.

Seeing that the angles which the pieces make with each other are of such importance to the magnitude and the proportion of the excited strains, it is proper to find out some way of readily and compendiously conceiving and expressing this analogy.

In general the strain on any piece is proportional to the straining force. This is evident.

[1] The reader is requested to add accents to the extreme letters D and F of fig. 3, which correspond to the position of the beam AGD indicated by the dotted lines. Accents are also wanted to the upper F and the lower C and G in fig. 9; also to the upper F and lower G in fig. 10; and in this *b* should be C. In fig. 11, the *i* towards the left should be *t*, and an accent is wanting over the upper *f*. In fig. 12, the dotted line CK should be continued upward and marked I. In fig. 16. the letters should stand thus, A C E *e* D *f* F B.

Carpentry.

Secondly, the strain on any piece AC is proportional to the sine of the angle which the straining force makes with the other piece directly, and to the sine of the angle which the pieces make with each other inversely.

For it is plain that the three pressures AE, AF, and AG, which are exerted at the point A, are in the proportion of the lines AE, AF, and FE (because FE is equal to AG). But because the sides of a triangle are proportional to the sines of the opposite angles, the strains are proportional to the sines of the angles AFE, AEF, and FAE. But the sine of AFE is the same with the sine of the angle CAD, which the two pieces AC and AD make with each other; and the sine of AEF is the same with the sine of EAD, which the straining piece BA makes with the piece AC. Therefore we have this analogy, Sin. CAD : Sin. $\text{EAD} = \text{AE} : \text{AF}$, and $\text{AF} = \text{AE} \times \frac{\text{Sin. EAD}}{\text{Sin. CAD}}$. Now the sines of angles are most conveniently conceived as decimal fractions of the radius, which is considered as unity. Thus. *Sin.* 30° is the same thing with 0·5, or $\frac{1}{2}$; and so of others. Therefore, to have the strain on AC, arising from any load AE acting in the direction AE, multiply AE by the sine of EAD, and divide the product by the sine of CAD.

This rule shows how great the strains must be when the angle CAD becomes very open, approaching to 180 degrees. But when the angle CAD becomes very small, its sine (which is our divisor) is also very small; and we should expect a very great quotient in this case also. But we must observe, that in this case the sine of EAD is also very small; and this is our multiplier. In such a case, the quotient cannot exceed unity.

But it is unnecessary to consider the calculation by the tables of sines more particularly. The angles are seldom known any otherwise but by drawing the figure of the frame of carpentry. In this case, we can always obtain the measures of the strains from the same scale, with equal accuracy, by drawing the parallelogram AFCG.

Strains propagated to the points of support.

Hitherto we have considered the strains excited at A only as they affect the pieces on which they are exerted. But the pieces, in order to sustain, or be subject to, any strain, must be supported at their ends C and D; and we may consider them as mere intermediums, by which these strains are made to act on those points of support: Therefore AF and AG are also measures of the forces which press or pull at C and D. Thus we learn the supports which must be found for these points. These may be infinitely various. We shall attend only to such as somehow depend on the framing itself.

Action of a straining beam.

Such a structure as fig. 11 very frequently occurs, where a beam BA is strongly pressed to the end of another beam AD, which is prevented from yielding, both because it lies on another beam HD, and because its end D is hindered from sliding backwards. It is indifferent from what this pressure arises: we have represented it as owing to a weight hung on at B, while B is withheld from yielding by a rod or rope hooked to the wall. The beam AD may be supposed at full liberty to exert all its pressure on D, as if it were supported on rollers lodged in the beam HD; but the loaded beam BA presses both on the beam AD and on HD. We wish only to know what strain is borne by AD.

All bodies act on each other in the direction perpendicular to their touching surfaces; therefore the support given by HD is in a direction perpendicular to it. We may therefore supply its place at A by a beam AC, perpendicular to HD, and firmly supported at C. In this case, therefore, we may take AE, as before, to represent the pressure exerted by the loaded beam, and draw EG perpendicular to AD, and EF parallel to it, meeting the perpendicular AC in F. Then AG is the strain compressing AD, and AF is the pressure on the beam HD.

The form of the abutting joint of no great importance.

It may be thought, that since we assume as a principle that the mutual pressures of solid bodies are exerted perpendicular to their touching surfaces, this balance of pressures, in framings of timbers, depends on the directions of their butting joints; but it does not, as will readily appear by considering the present case. Let the joint or abutment of the two pieces BA, AD, be mitred in the usual manner, in the direction *f*A*f'*. Therefore, if A*c* be drawn perpendicular to A*f*, it will be the direction of the actual pressure exerted by the loaded beam BA on the beam AD. But the re-action of AD, in the opposite direction A*t*, will not balance the pressure of BA; because it is not in the direction precisely opposite. BA will therefore slide along the joint, and press on the beam HD. AE represents the load on the mitre joint A. Draw E*c* perpendicular to A*c*, and E*f* parallel to it. The pressure AE will be balanced by the re-actions *c*A and *f*A; or, the pressure AE produces the pressures A*c* and A*f*, of which A*f* must be resisted by the beam HD, and A*c* by the beam AD. The pressure A*f* not being perpendicular to HD, cannot be fully resisted by it; because (by our assumed principle) it re-acts only in a direction perpendicular to its surface. Therefore draw *fp*, *fi*, parallel to HD, and perpendicular to it. The pressure A*f* will be resisted by HD with the force *p*A; but there is required another force *i*A, to prevent the beam BA from slipping outwards. This must be furnished by the re-action of the beam DA. (See Note BB.) In like manner, the other force A*c* cannot be fully resisted by the beam AD, or rather by the prop D, acting by the intervention of the beam; for the action of that prop is exerted through the beam in the direction DA. The beam AD, therefore, is pressed to the beam HD by the force A*c*, as well as by A*f*. To find what this pressure on HD is, draw *cg* perpendicular to HD, and *co* parallel to it, cutting EG in *r*. The forces *g*A and *o*A will resist, and balance A*c*.

Thus we see that the two forces A*c* and A*f*, which are equivalent to AE, are equivalent also to A*p*, A*i*, A*o*, and A*g*. But because A*f* and *c*E are equal and parallel, and E*r* and *fi* are also parallel, as also *cr* and *fp*, it is evident, that *if* is equal to *r*E, or to *o*F, and *i*A is equal to *rc*, or to G*g*. Therefore the four forces A*g*, A*o*, A*p*, A*i*, are equal to AG and AF. Therefore AG is the compression of the beam AD, or the force pressing it on D, and AF is the force pressing it on the beam HD. The proportion of these pressures, therefore, is not affected by the form of the joint.

This remark is important; for many carpenters think the form and direction of the butting joint of great importance; and even the theorist, by not prosecuting the general principle through *all* its consequences, may be led into an error. The form of the joint is of no importance, in as far as it affects the strains in the direction of the beams; but it is often of great consequence, in respect to its own firmness, and the effect it may have in bruising the piece on which it acts, or being crippled by it.

Origin of the strain on a tie-beam.

The same compression of AB, and the same thrust on the point D by the intervention of AD, will obtain, in whatever way the original pressure on the end A is produced. Thus, supposing that a cord is made fast at A, and pulled in the direction AE, and with the same force, the beam AD will be equally compressed, and the prop D must re-act with the same force.

But it often happens that the obliquity of the pressure on AD, instead of compressing it, stretches it; and we desire to know what tension it sustains. Of this we have a familiar example in a common roof. Let the two rafters AC, AD (fig. 12), press on the tie-beam DC. We may

Carpentry.

suppose the whole weight to press vertically on the ridge A, as if a weight B were hung on there. (See Note CC.) We may represent this weight by the portion A*b* of the vertical or plumb line, intercepted between the ridge and the beam. Then drawing *bf* and *bg* parallel to AD and AC, A*g* and A*f* will represent the pressures on AC and AD. Produce AC till CH be equal to A*f*. The point C is forced out in this direction, and with a force represented by this line. As this force is not perpendicularly across the beam, it evidently stretches it; and this extending force must be withstood by an equal force pulling it in the opposite direction. This must arise from a similar oblique thrust of the opposite rafter on the other end D. We concern ourselves only with this extension at present; but we see that the cohesion of the beam does nothing but supply the balance to the extending forces. It must still be supported externally, that it *may resist*, and by resisting obliquely, be stretched. The points C and D are supported on the walls, which they press in the directions CK and DO, parallel to A*b*. If we draw HK parallel to DC, and HI parallel to CK (that is to A*b*), meeting DC produced in I, it follows from the composition of forces, that the point C would be supported by the two forces KC and IC. In like manner, making DN = A*g*, and completing the parallelogram DMNO, the point D would be supported by the forces OD and MD. If we draw *go* and *fk* parallel to DC, it is plain that they are equal to NO and CI, while A*o* and A*k* are equal to DO and CK, and A*b* is equal to the sum of DO and CK (because it is equal to A*o* + A*k*). The weight of the roof is equal to its vertical pressure on the walls.

Thus we see, that while a pressure on A, in the direction A*b*, produces the strains A*f* and A*g*, on the pieces AC and AD, it also excites a strain CI or DM in the piece DC. And this completes the mechanism of a frame; for all derive their efficacy from the triangles of which they are composed, as will appear more clearly as we proceed.

External action of a frame.

But there is more to be learned from this. The consideration of the strains on the two pieces AD and AC, by the action of a force at A, only showed them as the means of propagating the same strains in their own direction to the points of support. But, by adding the strains exerted in DC, we see that the frame becomes an intermedium, by which exertions may be made on other bodies in certain directions and proportions, so that this frame may become part of a more complicated one, and, as it were, an element of its constitution. It is worth while to ascertain the proportion of the pressures CK and DO, which are thus exerted on the walls. The similarity of triangles gives the following analogies:

$$\mathrm{DO} : \mathrm{DM} = \mathrm{A}b : b\mathrm{D}$$
$$\mathrm{CI, or\ DM} : \mathrm{CK} = \mathrm{C}b : \mathrm{A}b$$
$$\mathrm{Therefore\ DO} : \mathrm{CK} = \mathrm{C}b : b\mathrm{D}.$$

Or, *the pressures on the points* C *and* D, *in the direction of the straining force* A*b*, *are reciprocally proportional to the portions of* DC *intercepted by* A*b*.

Also, since A*b* is = DO + CK, we have

$$\mathrm{A}b : \mathrm{CK} = \mathrm{C}b + b\mathrm{D}\ (\mathrm{or\ CD}) : b\mathrm{D}, \text{ and}$$
$$\mathrm{A}b : \mathrm{DO} = \mathrm{CD} : b\mathrm{C}.$$

In general, any two of the three parallel forces A*b*, DO, CK, are to each other in the reciprocal proportion of the parts of CD, intercepted between their directions and the direction of the third.

And this explains a still more important office of the frame ADC. If one of the points, such as D, be supported, an external power acting at A, in the direction A*b*, and with an intensity which may be measured by A*b*, may be set in equilibrio with another acting at C, in the direction CL, opposite to CK or A*b*, and with an intensity represented by CK; for since the pressure CH is partly withstood by the force IC, or the firmness of the beam DC supported at D, the force KC will complete the balance. When we do not attend to the support at D, we conceive the force A*b* to be balanced by KC, or KC to be balanced by A*b*. And, in like manner, we may neglect the support or force acting at A, and consider the force DO as balanced by CK.

Thus our frame becomes a lever, and we are able to trace the interior mechanical procedure which gives it its efficacy: it is by the intervention of the forces of cohesion, which connect the points to which the external forces are applied with the supported point or fulcrum and with each other.

It becomes a lever.

These strains or pressures A*b*, DO, and CK, not being in the directions of the beams, may be called *transverse*. We see that by their means a frame of carpentry may be considered as a solid body: but the example which brought this to our view is too limited for explaining the efficacy which may be given to such constructions. We shall therefore give a general proposition, which will more distinctly explain the procedure of nature, and enable us to trace the strains as they are propagated through all the parts of the most complicated framing, finally producing the exertion of its most distant points.

General proposition.

We presume that the reader is now pretty well habituated to the conception of the strains as they are propagated along the lines joining the points of a frame, and we shall therefore employ a very simple figure.

Let the strong lines ACBD (fig. 13) represent a frame of carpentry. Suppose that it is pulled at the point A by a force acting in the direction AE, but that it rests on a fixed point C, and that the other extreme point B is held back by a power which resists in the direction BF: It is required to determine the proportion of the strains excited in its different parts, the proportion of the external pressures at A and B, and the pressure which is produced on the obstacle or fulcrum C.

It is evident that each of the external forces at A and B tend one way, or to one side of the frame, and that each would cause it to turn round C if the other did not prevent it; and that if, notwithstanding their action, it is turned neither way, the forces in actual exertion are in equilibrio by the intervention of the frame. It is no less evident that these forces concur in pressing the frame on the prop C. Therefore, if the piece CD were away, and if the joints C and D be perfectly flexible, the pieces CA, CB, would be turned round the prop C, and the pieces AD, DB, would also turn with them, and the whole frame change its form. This shows, by the way, and we desire it to be carefully kept in mind, that the firmness or stiffness of framing depends entirely on the triangles bounded by beams which are contained in it. An open quadrilateral may always change its shape, the sides revolving round the angles. A quadrilateral may have an infinity of forms, without any change of its sides, by merely pushing two opposite angles towards each other, or drawing them asunder. But when the three sides of a triangle are determined, its shape is also invariably determined; and if two angles be held fast, the third cannot be moved It is thus that, by inserting the bar CD, the figure becomes unchangeable; and any attempt to change it by applying a force to an angle A, immediately excites forces of attraction or repulsion between the particles of the stuff which form its sides. Thus it happens, in the present instance, that a change of shape is prevented by the bar CD. The power at A presses its end against the prop; and in doing this it puts the bar AD on the stretch, and also the bar DB. Their places might therefore be supplied by cords or metal wires. Hence it is evident that

DC is compressed, as is also AC; and, for the same reason, CB is also in a state of compression; for either A or B may be considered as the point that is impelled or withheld. Therefore DA and DB are stretched, and are resisting with attractive forces. DC and CB are compressed, and are resisting with repulsive forces; and thus the support of the prop, combined with the firmness of DC, puts the frame ADBC into the condition of the two frames in fig. 8 and fig. 9. Therefore the external force at A is really in equilibrio with an attracting force acting in the direction AD, and a repulsive force acting in the direction AK. And since all the connecting forces are mutual and equal, the point D is pulled or drawn in the direction DA. The condition of the point B is similar to that of A, and D is also drawn in the direction DB. Thus the point D, being urged by the forces in the directions DA and DB, presses the beam DC on the prop, and the prop resists in the opposite direction. Therefore the line DC is the diagonal of the parallelogram, whose sides have the proportion of the forces which connect D with A and B. This is the principle on which the rest of our investigation proceeds. We may take DC as the representation and measure of their joint effect. Therefore draw CH, CG, parallel to DA, DB. Draw HL, GO, parallel to CA, CB, cutting AE, BF, in L and O, and cutting DA, DB, in I and M. Complete the parallelograms ILKA, MONB. Then DG and AI are the equal and opposite forces which connect A and D; for GD = CH = AI. In like manner DH and BM are the forces which connect D and B.
